Antibacterial activity. MIC values showed different susceptibilities of *Streptococcus pneumoniae* isolates to AEO and antibiotics (tab. II). Almost all combinations AEO-amoxicillin showed indifferent effects (FIC index=1.015-2). Additive effects on *S. pneumoniae 4566* (FIC index=1) and *4723* (FIC index=0.62 and 0.75) isolates were noticed for one and two combinations, respectively. It is worthy to note that one combination determined a weak synergistic effect on *S. pneumoniae 4723* isolate (FIC index=0.5) (tab. III). In case of combinations AEO-ciprofloxacin, only one showed an additive effect (FIC index=0.62); all the others developed indifferent effects (FIC index=1.03-2). In this study no antagonistic interactions were noticed suggesting that the co-administration of herbal products containing AEO with amoxicillin or ciprofloxacin will not affect the activity of these antibiotics in infections with *Streptococcus pneumoniae* strains.

Antagonistic interactions between plant extracts, essential oils or even phytochemicals and antibiotics have already been men-

tioned in literature. The combination *Coriandrum sativum* essential oil-cephalotin showed antagonistic effects on a large number of bacteria (*Escherichia coli*, *Staphylococcus aures*, *Pseudomonas pyocyaneus*, *Micrococcus luteus*, *Mycobacterium smegmatis*, *Yersinia enterocolitica*) (15). Essential oils of *Melaleuca alternifolia*, *Thymus vulgaris*, *Mentha piperita* and *Rosmarinus officinalis* in combination with amphotericin B showed mainly antagonistic effects on *Candida albicans* (13).

TABLE II

Antibacterial activity of anise essential oil, amoxicillin and ciprofloxacin against *Streptococcus pneumoniae* clinical isolates

Clinical isolate	MIC (mg/mL)		
	AEO	Amox	Cipro
S. pneumoniae 4409	12.5	0.12×10^{-3}	1×10^{-3}
S. pneumoniae 4546	6.25	0.03×10^{-3}	0.5×10^{-3}

CONCLUSIONS

The results of this study suggest that herbal products containing anise essential oil may be used as expectorants in combination with amoxicillin or ciprofloxacin in *Streptococcus pneumoniae* infections without diminishing antibiotic efficacy.

It is obvious that an extensive investigation on a large number of clinical isolates is needed to confirm the results reported in the present study.

ACKNOWLEDGEMENTS

The authors are grateful to the Microbiology Laboratory, Lung Clinical Hospital, Iasi, for providing the clinical isolates for this study.

NEWS

NEW TARGET FOR THE OLD ASPIRIN

Non-steroidal anti-inflammatory drugs (NSAIDs), such as aspirin, a classical and authentic cyclooxygenase (COX) inhibitor, reduces the risk of developing several types of cancer. On site of inflammation, induction of COX-2 quickly results in the biosynthesis of prostaglandins leading to inflammatory response. Overexpression of inducible COX-2 and an increased prostaglandin biosynthesis play a significant role in carcinogenesis. Ogawa and coworkers investigated the effect of aspirin on regional lymph node metastasis during the development of lung cancer in mice. The carcinoma model was obtained by injecting a solution containing Lewis lung carcinoma (LLC) cells overexpressing green fluorescent protein (GFP) and BD Matrigel in the male mice lungs. Operative mortality was 10%. Single pulmonary nodules developed at the implanted site in 95% of animals, and regional mediastinal lymph node metastasis were observed 14 days after LLC-GFP cell injection in mice. Aspirin was orally administered (100 mg/kg, twice a day) after LLC-GFP cell injection. The reducing of percentage metastasis to regional lymph nodes was observed beginning with day 12 (63%), with no significant suppression of primary tumor growth in the lungs. Aspirin treatment led to a significant reduction in mortality (survival rate 70%; $P < 0.0001$). The authors suggested that COX inhibitors have potential to prevent lymph node metastasis (Ogawa F, Amano H, Ito Y, Matsui Y et al. Aspirin reduces lung cancer metastasis to regional lymph nodes. *Biomed Pharmacother* 2014; 68:79–86).

NONCONVENTIONAL TECHNIQUES FOR SEPARATION OF BIOSYNTHETIC AMINO ACIDS (Abstract): Amino acids can be obtained by biosynthesis, by protein hydrolysis or by extraction from natural sources. The most efficient methods are the first two, but the separation of amino acids from fermentation broths or protein hydrolysates is rather difficult. Amino acids dissociate in aqueous solutions, forming characteristic ionic species depending on the solution pH-value. These properties make amino acids to be hydrophilic at any pH-value. This paper presents a review of the separation studies of some amino acids by nonconventional methods, namely individual or selective reactive extraction. Separation of some amino acids from their mixture obtained either by fermentation or protein hydrolysis by reactive extraction with different extractants indicated the possibility of the amino acids selective separation as a function of the pH-value of aqueous solution correlated with the acidic or basic character of each amino acid. **Keywords:** AMINO ACIDS, REACTIVE EXTRACTION, EXTRACTANT, DISSOCIATION CONSTANT, SELECTIVITY FACTOR

Amino acids represent one of the most important classes of biosynthetic compounds, being the main structural components of protein and enzymes. The growing interest for amino acids production is supported by their numerous applications in biology, biochemistry, food, pharmaceutical and chemical industry. They can be obtained by chemical synthesis, isolation from natural materials, biosynthesis and chemo-enzymatic methods (1, 2). The most promising methods for amino acids production are based on biosynthesis and protein hydrolysates, but the separation step is difficult and sometimes represents the main drawback of the biotechnological process (1-5).

The downstream processing of amino acids includes ion exchange, crystallization at the isoelectric point, chromatography, liquid-liquid extraction, aqueous two phase systems and liquid membrane (1, 4, 6). Recent studies approached the separation of amino acids by reactive extraction as an alternative for individual separation but most important for achieving selective separation of amino acids from various mixtures. Compared with solvent extrac-

tion, the reactive extraction implies the presence of an extractant added in solvent, compound that is capable to react with the solvent resulting a compound miscible only with the solvent and though increasing either the compound solubility or extraction selectivity (6-9).

Mechanism of amino acids separation by reactive extraction

Reactive extraction method have been used for the recovery of biosynthesis products (organic acids, antibiotics, vitamins, amino acids etc.) from aqueous solutions using an organic phase in which different extractants were added (10-14).

Amino acids are compounds that possess both amino and carboxyl groups (fig.1) and, depending on the functional side chain groups, they can have basic properties like arginine, acidic like glutamic acid, or neutral like glycine (2).

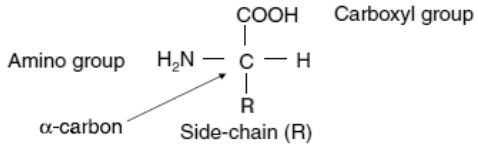

Fig. 1. General structure of amino acids

In aqueous solution, amino acids present amphoteric properties according to the following equilibrium (10):

$$^{-}H_3N-RCOOH \overset{K_{a1}}{\rightleftharpoons} H_2N-RCOOH \overset{K_{a2}}{\rightleftharpoons} H_2N-RCOO^{-}$$

If the pH of aqueous solution is lower than their corresponding dissociation constant (pKa) the amino groups are protonated, and ionized if the pH is above the respective pKa value.

The solubility of amino acids in nonpolar solvents is very low, the extraction using nonpolar solvent being very difficult. However, the extraction efficiency can be increased by the addition of cationic or anionic extractants which, at certain pH-values, below or above the isoelectric point of an amino acid can form complexes with amino acids, which are preferentially soluble in the organic phase (7, 15-17).

Separation of amino acids by reactive extraction is possible by using an extractant in the organic phase, like phosphoric acid derivates, high molecular weight quaternary aliphatic amines or crown ethers (7,17-21).

The reactive extraction of amino acids with an organophosphoric extractant (HP) occurs by means of an interfacial chemical reaction of the ion exchange type and implies the presence of amino acids in the cationic form (17):

$$R_1^{+}\text{-}CH(NH_3^{+})\text{-}COOH_{(aq)} + 2HP_{(o)} \rightleftharpoons R_1^{+}\text{-}CH(NH_3^{+})\text{-}COOH.P^{-}{}_{2\,(o)} + 2H^{+}_{(aq)}$$

The extraction of amino acids depends on the pKa values of the amino acids and the cationic extractant. A predicting model for extraction behavior of amino acids by cationic extractants was developed by Lukhezo et al. (23) and correlated well with the experimental data from extraction systems of individual amino acids with di(2-ethylhexyl)phosphoric acid(D2EHPA), di(2-ethylhexyl) monothio phosphoric acid (D2EHPA(S)), dinonyl naphthalene-sulphonic acid (DNNSA) and Versatic 10

(decanoic acid) in toluene. The main disadvantage of the extraction at low pH-value of aqueous phase is the co extraction of other cations existing in solution.

Extraction of amino acids with amine occur with the formation at the interface of hydrophobic ion pairs with the participation of the protonated amino acid (pH of the aqueous phase lower than the pH of isoelectric point of the amino acid), of an anion present in the aqueous solution and an extractant added in the organic solvent (17):

$$R\text{-}CH(NH3+)\text{-}COOH(aq) + A\text{-}(aq) + Q(o) \leftrightarrow R\text{-}CH(NH3+A\text{-})COOH.Q(o)$$

The reactive extraction with the amine salts requires the amino acid in the anionic form which occurs for pH-value of the aqueous phase greater than the pH of the amino acid isoelectric point. In the extraction system can be established the following equilibriums:

- dissociation of amino acid in the aqueous phase

$R\text{-}CH(NH_2)COOH_{(aq)} + HO^-_{(aq)} \leftrightarrow H_2O + R\text{-}CH(NH_2)COO^-_{(aq)}$

- reactive extraction of amino acid in the anionic form by an interfacial reaction of ion exchange type

$R\text{-}CH(NH_2)COOH^-_{(aq)} + QCl_{(o)} \leftrightarrow R\text{-}CH(NH_2)COO^-Q^+_{(o)} + Cl^-_{(aq)}$

- coextraction of hydroxyl group or of another anion present in aqueous phase

$HO^-_{(aq)} + QCl_{(o)} \leftrightarrow Q^+HO^-_{(o)} + Cl^-_{(aq)}$

Besides pH-value, the extraction of amino acids is influenced by the extractant concentration, surface-active substances in the system, the intensity of mixing, etc. One of the most important challenges in the separation of amino acids is the coextraction of other compounds present in the medium, like secondary amino acids, hydroxyl ions, affecting the extraction of the main solute. Some of them may exist in an ionic form, at the optimum pH of extraction, which can compete with primary amino acid and so decreasing the separation efficiency (24).

Separation of individual and mixture of amino acids

In order to achieve a high selectivity for extraction of different compounds from mixtures it is necessary to understand the mechanism and conditions for extraction process which is usually performed for every compound by studying the behavior of this in individual extraction systems.

Optimum conditions for recovery of amino acids are usually achieved by use of hydrophobic counter-ions. For example, Cascaval et. al (1996), Kelly et. al (1998), Smirnova et al. (2004) studied the extraction of amino acids with cationic extractants like D2EHPA and DNNSA. The cationic carrier di(2-ethylhexyl)phosphoric acid (D2EHPA) was widely used for extraction of amino acids because it is one of the most promising candidates for its chemical stability, high complexing ability, stripping characteristics, and extremely low solubility in aqueous acidic solutions (5,17,25).

Didi et al. (2009) studied the extraction of two aminoacids, phenylalanine and tyrosine, with different extractants: D2EHPA, TOPO (trioctylphosphine oxide) and TBP (tri n-butyl phosphate) dissolved in chloroform and Aliquat 336 (n-methyl-n,n-dioctyloctan-1-ammonium chloride) dissolved in kerosene (26). The experimental data indicated that the best extraction system for phenylalanine was the one with D2EHPA, the extraction yield being

82.12%, followed by D2EHPA + TBP (73.48%) and Aliquat 336 + kerosene (30.1%). Reactive extraction of tyrosine with D2EHPA or Aliquat 336 showed the highest yield of 23.4% and 22.4% respectively. Once more, the authors highlighted that the separation yield is controlled by the pH-value of the aqueous phase, which is due to the acidic or basic character of each amino acid (26).

The extraction of phenylglycine in alkaline solution using TOMAC (tri-n-octylmethylammonium chloride) as extractant dissolved in1-decanol was studied by Munoz et al. (10). The authors quantified the extraction yield as a function of the chloride/phenylglycine initial molar ratio and the influence of water coextraction on the extraction efficiency. As shown in figure 2, the extraction yield increases with the chloride/phenylglycine initial molar ratio, for the same initial hydroxide ion concentration, decreases when the initial hydroxide ion concentration is increased for the same chloride/phenylglycine initial molar ratio, and reaches an asymptotic value due to the limited amount of phenylglycine and hidroxyl ions to be extracted.

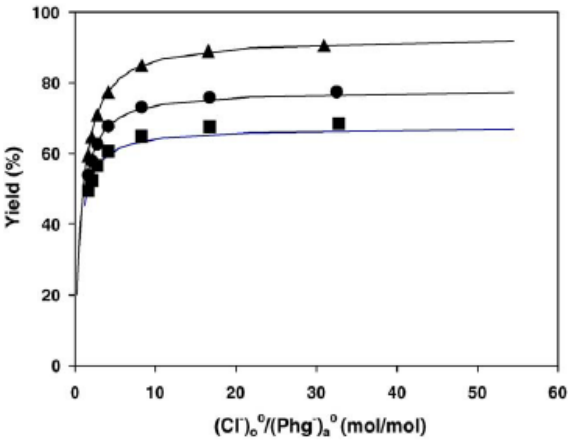

Fig. 2. Extraction yield of phenylglycine as function of chloride/phenylglycine initial molar ratio. $[Phg^-]^0_a$ = 3.3–66.1 mM, *Va*/*Vo* = 2.
(▲) $[OH^-]^0_a$ = 10 mM; (●) $[OH^-]^0_a$ = 50 mM; (■) $[OH^-]^0_a$ = 100 mM.

There are some studies where the separation of phenylalanine was performed for high values of aqueous phase pH, using TOMAC, Adogen 464 or Amberlite LA-2 dissolved in xylene (26,27). Thus, Cameron et al (2001) studied the recovery of amino acids from aqueous solutions by reactive extraction using a mixture of extractants: D2EHPA and Aliquat 336 dissolved in methyl isobutyl ketone (26). By using this extraction system it was possible to extract phenylalanine for large range of aqueous phase pH from 1.8-9.2. When using only the Aliquat 336 in methyl isobutyl ketone for extraction of phenylalanine, the extraction mechanism involves an ion exchange reaction between chloride ion of extractant and the amino acid anion. The formation of 2:1 complexes form was explained by the possibility of formation of hydrogen bonds

between the amino acid zwitterion form and a complex amino acid / extractant. If the extraction is carried out using only D2EHPA, at the formation of the interfacial complex participates one molecule of amino acid and one molecule of extractant (27).

Extraction of tryptophan and tyrosine from basic solutions using TOMAC, as extractant, dissolved in xylene requires the amino acids to be in anionic form, a pH-value with at least two units greater than the corresponding value of pK_{NH2} = 9.39. Tyrosine extraction occurs by formation of dianions by proteolyses of the phenolic proton, pH_{OH} = 10.07 at pH greater than 12. At the end of the extraction process, tryptophan remains in the organic phase, whereas tyrosine is transferred into the aqueous phase thus the selective separation can be achieved (28).

Caşcaval et al. (1996) studied the extraction of glutamic acid using Amberlite LA-2, dissolved in butyl acetate. It was observed that the pH of the aqueous phase or of the emulsion has a very important influence on the yield of extraction. Increasing the pH-value from 0.5 to pH = 3.2, corresponding to the isoelectric point, leads to a decrease of the extraction efficiency from 98% to 0%. At low pH-values corresponding to the first stage of glutamic acid ionization, pK_1, the amino acid is found only in the protonated form. Consequently, the reactive extraction processes involve the protonated glutamic acid and the anion derived from sulfuric acid (used to change the pH) in the aqueous phase and extractant in the organic phase. The complex formed is of ion pair type and it is soluble only in the organic phase. The coefficients for individual mass transfer (tab. I) were determined for three values of pH and three concentrations of the extractant (29).

TABLE I

Values of the individual mass transfer coefficients

Extractant concentration, g/l	**pH**	**$k \cdot 10^2$, s^{-1}**
64	1.5	2.66
92	0.5	4.60
92	1.5	4.00
92	2.0	0.67
166	1.5	5.00

In another study, Cascaval et al. analyzed the possibility to extract individual amino acids with basic, acidic or neutral character by reactive extraction systems with D2EHPA as extractant dissolved in butyl acetate. In all cases, the extraction degree increases with the increase of pH value, reaches a maximum for a pH extraction domain of about 2-3 pH units, followed by a sharp decrease. The maximum is the result of the two opposite phenomena which occur as pH-value increases: increase of the concentration of the extractant active form which is able to react with the amino acid and decrease of the total amount of amino acid present in cationic form (17).

Reactive extraction of the acidic amino acids: aspartic acid, glutamic acid occurs with high efficiency at pH = 2.5, the extraction degree being comparable: 77% for aspartic acid and 80% for glutamic acid (figure 3).

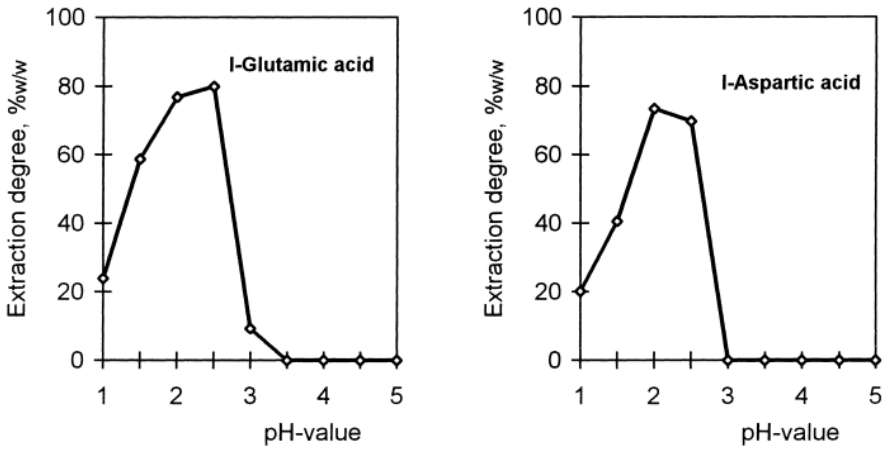

Fig. 3. Effect of aqueous solution pH-value on the reactive extraction degrees of acidic amino acids with D2EHPA dissolved in butyl acetate.

Due to the increasing concentration of the zwitterions of both amino acids in the aqueous phase, any further increase of pH leads to strong decrease of the extraction degree. At the isoelectric point of each amino acid reactive extraction becomes ineffective (17). For extraction system of neutral amino acids (l-glycine, l-alanine, l-tryptophan, l-cysteine), the maximum extraction yields were obtained at pH = 3 and depend on the amino acid hydrophobicity, the values varying between 78.4% for l-glycine and 90% for tryptophan. For pH-values higher than 3, the separation efficiency decreases, as a result of the amino acid carboxyl group dissociation and reaches zero at the corresponding value of isoelectric point. The maximum separation yield for the basic amino acids studied (l-histidine, l-lysine, l-arginine) varies between 57.8% w/w for l-histidine and 68% w/w for l-lysine and l-arginine, being reached at pH-value of 2.5–3. The difference is due to the more pronounced dissociation of l-histidine at this pH-value and, thus, to the formation of dication-anionic species in aqueous solution. The increase of pH-value leads to a significant decrease of the extraction degrees, which become 0 at pH 4 for l-histidine, and pH = 5 for the other two amino acids (17).

Selective separation of amino acids from fermentation broths is currently an intensively studied problem. Analysis of the correlation between the extraction constant the pH at isoelectric point and the hydrophobicity of amino acids is a precondition to achieve selectivity for extraction of these compounds.

Kelly et al. (1998) studied the extraction and fractionation of mixtures of amino acids by some cationic extractants with varying acid dissociation constants (D2EHPA, DNNSA, D2EHPA(S) and Versatic 10) dissolved in toluene. The authors evaluated the separation factors, as the ratio of partition coefficients, between amino acids with similar chemical structures. The amino acid mixture included arginine, phenylalanine, glycine, alanine and aspartic acid. It was observed that the extraction capacities for the amino acids, subject to the extractants,

were generally found to decrease in the order arginine < phenylalanine < alanine < glycine < aspartic acid. In order to achieve high efficiency of selective extraction (over 80%) the experiments were performed using an excess of cationic extractants, their concentrations being: 4 times for DNNSA, 400 times D2EHPA and D2EHPA(S) and 1000 times Versatic that of amino acid concentrations. The separation factor of amino acids with similar chemical structure, defined as the ratio of the distribution coefficient between two amino acids, were calculated for different pH-values and for used extractant, except Versatic 10 (in which extraction was poor). The highest values for extraction efficiency and the separation factor were obtained for the extraction system with DNNSA (tab. II). Extractive loading capabilities of the extractants were found to decrease in the order DNNSA < D2EHPA(s) < D2EHPA < Versatic 10.

TABLE II

Separation factor of amino acids at different pH-values by DNNSA

Amino acid pairing	Separation factor				
	pH = 1	pH = 1.5	pH = 2.5	pH = 3	pH = 3.5
arginine-henylalanine	9.4	11.0			
phenylalanine-alanine		16.7	11.5	6.3	3.6
alanine-glycine		4.8	5.4	7.8	11.9
glycine-aspartic acid		2.7	3.0	3.0	

Selective separation of some amino acids was the aim of the study performed by Caşcaval et al. (2001). The authors studied the separation by reactive extraction with D2EHPA in butyl acetate of amino acids with acidic character (aspartic acid, glutamic acid), basic character (histidine, lysine, arginine) and neutral character (glycine, tryptophan, cysteine, alanine). Due to the rather low extraction degrees of each group of amino acids at the required pH-values for selective separation, for total recovery of the considered amino acids a multistage extraction has to be used (tab. III).

TABLE III

The experimental conditions for the reactive extraction and separation of amino acids from a mixture

Extracted amino acids	pH domain	One stage extraction degree (% w/w)	Number of extraction stages
Neutral amino acids	5–5.5	20-25	9
Acidic amino acids	2–2.5	60-63	3
Basic amino acids	4–4.5	18-25	10

By means of the pH influence on reactive extraction of the considered amino acids, an operation flow for selective separation has been elaborated and demonstrated experimentally.

Using multistage extraction, the total separation of the following amino acids groups has been performed: neutral amino acids (l-glycine, l-alanine, l-tryptophan) at pH 5–5.5, basic amino acids (l-lysine, l-

arginine) and l-cysteine at pH 4–4.5, l-histidine at pH 3–3.5, and acidic amino acids (l-aspartic acid, l-glutamic acid) at pH 2–2.5 (17).

FATIGUE LIFE OF RECIPROC AND MTWO INSTRUMENTS SUBJECTED TO STATIC AND DYNAMIC TESTS

This study evaluated the influence of flexibility and reciprocating movement on the fatigue life of endodontic instruments subjected to static and dynamic tests. The rotary nickel-titanium instruments used in this study were Reciproc and Mtwo. The instruments were initially subjected to a cantilever-bending test and then to static and dynamic fatigue tests. Reciproc instruments were operated in reciprocating movement, whereas Mtwo instruments were worked in continuous rotation. The means of bending resistance (maximum load in grams) of the instruments were 274.9 for Reciproc and 429 for Mtwo. The mean times (in seconds) to fracture of the instruments subjected to static and dynamic tests were 214.5 (static) and 286.3 (dynamic) for Reciproc and 38.9 (static) and 99 (dynamic) for Mtwo. The Student's t test revealed significant differences in all tests ($P < .05$). The results of the present study showed longer fatigue life for instruments with higher flexibility, driven by reciprocating movement, and in the dynamic testing model. These findings reinforce the assumption that use of reciprocating movement is a means to prolong the fatigue life of rotary nickel-titanium endodontic instruments during instrumentation of curved canals (Lopes HP, Elias CN, Vieira MV, Siqueira JF Jr, Mangelli M, Lopes WS, Vieira VT, Alves FR, Oliveira JC,Soares TG. Fatigue Life of Reciproc and Mtwo instruments subjected to static and dynamic tests. *J Endod*. 2013; 39(5): 693 – 696).

CHITOSAN/HYALURONIC ACID POLYELECTROLYTE COMPLEX HYDROGELS IN THE MANAGEMENT OF BURN WOUNDS (Abstract): **Aim:** This paper is a short review on the state-of-the-art of the use of polyelectrolyte complexes containing polysaccharides for wound and burn healing and treatment using the chitosan/hyaluronic acid polyelectrolyte complex (PEC) hydrogel. **Results and conclusions**: PEC is suitable for wound healing because a wet treatment can be realized and both components of PEC contribute by their properties to the enhanced antimicrobial activity, promote wound healing and prevent wound damage during treatment. **Keywords**: WOUND HEALING, DRESSING, CHITOSAN, HYALURONIC ACID.

Contamination and infection remain serious complications of wound burns and sepsis is a leading cause of mortality and morbidity in patients with major burns. Several factors contribute to the colonization of wounds, including the presence of: serous exudates that contain several proteins providing nutrients for bacteria, necrosed tissue that enhances the proliferation of micro-organisms and their invasion of the underlying viable tissues, and a compromised immune response that prevents the full expression of natural defenses (1). Initially, a burn is sterile, but rapidly becomes colonized, predominantly by Gram positive bacteria in the first instance (2). Once bacterial density reached up to 10^5/g of tissue, wound infection and sepsis are likely to occur. Early application of topical antimicrobial agents is the most effective way of preventing invasive burn infection when combined with early eschar excision (3).

Wound healing is an intricate process in which the skin (or another organ-tissue) repairs itself after injury. It is a particular biological process related to general phenomenon of growth and tissue regeneration. Wound healing progresses by a series of independent overlapping steps such as hemostasis, inflammation, migration/granulation/proliferation and maturation phases of tissue formation, matrix remodeling/reshaping/ and reepithelialization, in which a variety of cellular and matrix components act together to re-establish affected tissue integrity and to replace the

lost tissue (4).

Dressings are applied on open wounds for centuries to protect them from injuries and bacterial invasion. Recently, dressings made from novel polymers are used for the delivery of drugs to acute, chronic, and other types of wounds. Many types of dressings, of occlusive or semi-occlusive nature have been developed. These include collagen/glicosaminoglican sponges, alginate gels, hydrocolloids, hydrogels, polyurethane, collagen, chitosan (CS), pectin and hyaluronic acid-based biomaterials. CS has a beneficial influence in all stages of wound healing (5). Wet dressings have a superior quality because the controlled wet medium at the interface wound- bandage favors wound healing (6).

CHITOSANS (CSs) are polycationic copolymers of β -(1 - 4)-2-acetamido-2-deoxy-D-glucopyranose (deacetylated units) and 2-amino-2-deoxy-D-glucopyranose *N*-acetyl-D-glucosa-mine (acetylated units) as chitin derivatives with different deacetylation degrees (from 70 to 95%) and average molecular weight ranges from 10 to 1.000 kDa (7, 8) (fig. 1).

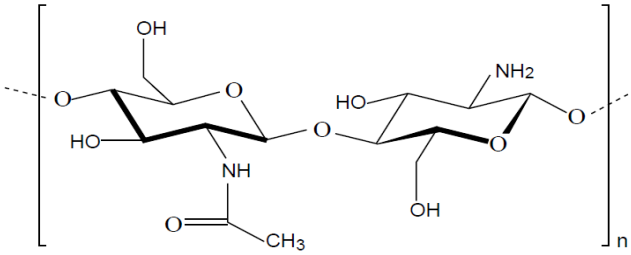

Fig. 1. The CS structure

Chitosan exhibits a good biocompatibility and biodegradability (9) which allows its wide medical applications as topical formulation in ophthalmology, as implants (10) or injection (11), and facilitates the penetration of hydrophilic drugs across mucosal epithelia. Because of the positive charges at physiological pH, CS is a good bioadhesive, increasing the retention to the application sites, efficient for wound healing (12) also because of its bacteriostatic effect (13).

Many studies have reported on the use of chitin, CS, and their derivatives as wound healing accelerators (>75 %) (14), acting in each stage of the healing process by enhancing the functions of the inflammatory cells polymorphonuclear leukocytes, macrophages, fibroblasts or osteoblasts, and by increasing the resistance to wound extension (15).

To further improve the CS properties, chemical modification and copolymerization are applied. These techniques could lead to the formation of entities with unknown toxicological profiles, therefore they should be avoided and the strategies based on non-covalent bonding preferred, this being achieved by electrostatic forces, hydrophobic or hydrogen bonding. Amino groups C_2 position in glucopyranosic units of CS can electrostatically interact with anionic groups (e.g. carboxyl) of polyanions of natural origin (such as pectine, alginate, carrageenan, xanthan gum, carboxymethyl cellulose, chondroitin sulphate, dextran sulphate, hyaluronic acid) or syn-

thetic origin (e.g. polyacrylic acid, polyphosphoric acid, poly(L-lactide) forming polyelectrolyte complexes (PEC) (16).

Hyaluronic acid (HA) was discovered by *Meyer and Palmer* in 1934 in the vitreous humor of bovine eyes. Hyaluronic acid (also called hyaluronan or hyaluronate) is the only nonsulphated glycosaminoglycan found in the extracellular matrix throughout connective, epithelial and neural tissues. Hyaluronic acid is a naturally occurring physiological constituent of the connective tissue, especially in the gingival mucosa (17). It is a glycosaminoglycan, a linear anionic polysaccharide, composed of repeating disaccharides, α-(1,4)-D-glucuronic acid, and β-(1,3)-N-acetyl-D-glucosamine linked by β-(1 - 3) bonds (fig. 2).

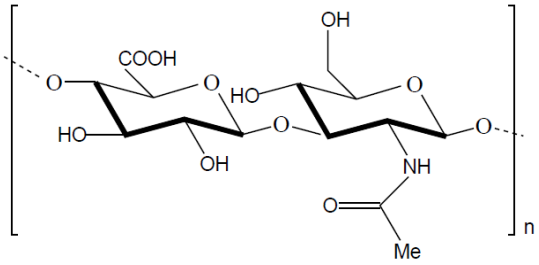

Fig. 2. The hyaluronic acid structure

HA is produced by bacterial fermentation of a *Streptococcus* sp. or is extracted for commercial purpose from rooster combs, umbilical cords, synovial fluids, or vitreous humour. It has been used in ophthalmic surgery, arthritis treatment, in tissue engineering, component of scaffolds for wound healing and implants devices (18). The implants covered with HA and its derivatives reduce adsorption, adhesion and cellular proliferation of *Staphlococcus aureus* at least 100 times (19).

HYDROGELS are macromolecular networks swollen in water or biological fluids. Hydrogels are often divided into three classes depending on the nature of their network, namely entangled networks, covalently cross linked networks, and networks formed by physical interactions, but a clear differentiation between them does not exist. Chemical hydrogels are formed by irreversible covalent bonds, while physical hydrogels are formed by various reversible links. These can be ionic interactions, as in ionically cross linked hydrogels and polyelectrolyte complexes (PEC), or secondary interactions, as in CS/poly (vinyl alcohol) (PVA) complexed hydrogels, grafted CS hydrogels and entangled hydrogels. The latter are formed by solubilization of CS in an acidic aqueous medium and their use is limited by their lack of mechanical strength and tendency to dissolve (20).

Due to the potential toxicity of free unreacted covalent cross linkers, which require an additional purification step during hydrogel manufacturing, the development of alternative types of hydrogels was necessary and desirable. Hydrogels formed by direct interaction between polymeric chains without the addition of cross linkers were prepared by complexation with another polymer or by aggregation after grafting.

POLYELECTROLYTE COMPLEX HYDROGELS (PECs)

Polyelectrolyte complex hydrogels are formed by ionic crosslinking (of ions or ionic molecules with high molecular weight, and in the case of polyelectrolytes with a certain distribution of molecular weight) and are generally biocompatible networks exhibiting interesting swelling characteristic, being an alternative to covalently cross linked hydrogels. Electrostatic attraction between amino cationic groups of CS and anionic carboxyl group of HA is the main and the strongest interaction in this PEC (fig. 3).

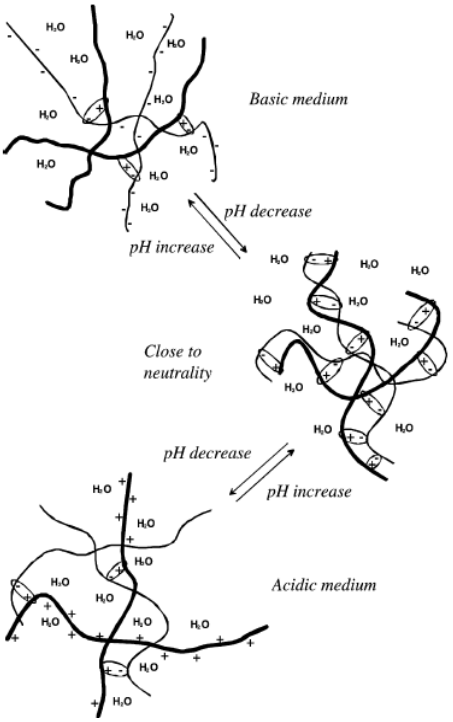

Fig. 3 pH-dependent structure and swelling of PEC containing a polysaccharide (as CS): - negative charges (HA), + positive charges (CS), ⬭ ionic interactions, —— CS; —— HA (adapted from 25)

BIO-SMART HYDROGELS rapidly respond to the action of external stimuli (or local environmental variations) by changes in the internal structure, size, volume, refraction index, and mechanical properties of the network. They are considered superabsorbent materials because they can absorb a high amount of water (solvent), hundred times their weight. Compared to covalently cross linked hydrogels, PEC has a higher swelling sensitivity, especially to pH changes, which led to a wide variety of applications. Bio-smart polysaccharidic hydrogels show good biocompatibility and bacteriostatic properties necessary for wound healing (20).

PEC PREPARATION

CS or its positively charged derivatives, such as glycol CS (21) or N-dodecylated CS (22), and HA are used. The reaction occurs in aqueous solution, this being the main advantage over covalent crosslinking, because biocompatibility is assured and purification before delivery avoided. Both polymers should be in ionized state and bear opposite charges, therefore the reaction can only occur at a pH value close to the pK interval of both polymers; pK_a of CS is ~ 6.5 (23) while that of HA is about 3.0 (24). During complexation, polyelectrolyte may coacervate or form a less compact hydrogel; if interactions are very strong precipitation occurs. Precipitation is very frequent and hinders hydrogel formation. It can be avoided by weakening the electrostatic interaction, adding salts such as NaCl. The presence of salts reduces the interaction between electrolytes by the contribution of the ions in the reaction environment. Phase separation usually does not occur, and a viscous, macroscopically homogeneous mixture, which may gel

when temperature is lowered, is obtained (25). Other factors affecting PEC properties are: pH, temperature, ionic strength, order of mixing, as well as polymer flexibility, molecular weight, degree of deacetylation of CS, and substitution degree of both polymers when derivatives are used. Injectable hydrogels for *in vitro* delivery of an adipogenic factor of insulin and adipose tissue engineering have been prepared by Schiff-base reaction between *N*-succinyl-CS and aldehyde of hyaluronic acid (26) and HA/CS polyelectrolyte complexes were obtained also by electro spinning (27).

PEC PROPERTIES

Stoichiometric PECs contain equal amounts of oppositely charged polyions, so the resulted PEC will have zero overall net charge, are usually insoluble and precipitate from solution (28). CS properties are maintained in PEC and hydrogels, therefore these are very well tolerated by living organisms and can be used in various applications: controlled release systems, cell cultures, enzymes immobilization, tissue regeneration and wound healing. CS-HA PEC protects HA against enzymatic hydrolysis, but only at pH values different of the optimum for enzymatic activity. Cells proliferation and activity in wound healing is reduced comparatively with that of CS (29). Both swelling and release profiles are pH-responsive. In acidic medium polyacid is neutralized, and because of free amino groups of CS positive charges will be present within gels. Mutual repulsion and water penetration together with contraions to neutralize these charges will determine the swelling. In case of a prolonged immersion in water a shrinkage is observed, because of segmental mobility of polyelectrolyte chains in swollen state, which allow the completion of interpolyelectrolyte reaction (30). In basic medium the mechanism is the same, but swelling is induced by negative charges of the polyacid (31). This is the logical reason for sensibility of the swelling to the ions presence and swelling rate is controlled by diffusion of mobile ions and changes in ionization degree. Osmotic pressure and electrostatic repulsion are responsible for swelling, which control the network forces depending on elasticity. If swelling becomes too important, dissolution happens at certain pHs. To prevent dissolution, covalent crosslinking is applied, but this will create biocompatibility problems.

TISSUE REGENERATION AND WOUND HEALING USING CS/HA CONTAINING FORMULATIONS

CS, with a structure similar with that of glycosaminoglycans (GAG) is indicated for preparing PEC hydrogels with GAG polyanions, such as chondroitin sulphate or HA, useful in cartilage reconstruction and wound healing, which mimic the GAG-rich extracellular matrices of articular chondrocytes (32).

In vitro tests showed that these PECs could be used as carriers for chondrocyte transplant and/or scaffold for cartilage-like tissue engineering. PEC CS/ HA as sponges and films allow the culture of various specific cells, such as keratocytes, which produces skin matrix accelerating wound healing after skin ablation without inflammatory reactions and toxicity for animals (29). When PEC is obtained from chitosan and other biocompatible polymers, it can be applied as bandages or powders, which protect the wound, accelerate healing and prevent bacterial contamination (33).

Composite CS/HA films with high transparency can be prepared using glass or

polymethylmethacrylate substrates, but not with PTFE. With increasing HA amount, the films become rougher, increasing the water contact angle and water uptake and decreasing water vapor permeability, BSA adsorption and fibroblasts adhesion, all these being desirable characteristics for wound bandages. Comparatively with Vaseline, CS/HA films are more efficient in wound healing because they do not cause wound damage when the bandage is removed. (34). Rossi *et al*. (35) prepared blends of CS hydrochloride, 5-methyl-pyrrolidinone CS and HA by freeze-drying. Chlorhexidinediacetate was used as antimicrobial agent. HA decreased the hydration capacity but modulated the antimicrobial agent release. It was suggested that the mechanism of the antimicrobial activity of CS consists in the interaction of positively charged CS molecules with negatively charged microbial cell membranes, which leads to disruption of bacterial membrane and loss of protein and intracellular constituents (36).

CONCLUSIONS

PECs of chitosan with hyaluronic acid are suitable for wound healing because a wet treatment can be realized and both components of PEC contribute through their properties to the enhanced antimicrobial activity, promote wound healing and prevent wound damage during treatment. Polyelectrolyte complexation occurs under mild reaction conditions and biocompatible PEC systems are obtained. PEC hydrogels exhibit a highly pH-sensitive swelling, therefore they can be used for pH-controlled drug delivery in different conditions.

RESEARCH ON THE DEVELOPMENT OF BIOADHESIVE VAGINAL TABLETS CONTAINING 5-FLUOROURACIL (Abstract): Biomucoadhesive vaginal tablets are modern formulations used in current therapy to achieve controlled release of the active substance at the application site by maintaining the pharmaceutical preparation at that level. This can be achieved by using mucoadhesive substances with different mechanical and physical-chemical properties. Two cellulose derivatives of different viscosity, Metolose 90 SH 4000 and Metolose 90 SH 100000, and two types of polyacrylates with different cross linking degrees, Carbopol 71, low degree of cross linking, and Carbopol 974, high degree of cross linking were used. In a previous study twelve original formulations of bioadhesive vaginal tablets containing 100 mg 5-fluorouracil (5-FU) /tablet (F1-F12) were formulated, prepared and analyzed. The pharmacotechnical characterization of the bioadhesive vaginal tablets containing 5-FU was performed by determining their specific quality characteristics. For the optimization of formulations, the influence of formulation factors on some quality characteristics (mechanical strength, friability, disintegration time) which may be influenced by the nature and amount of auxiliary substances used was studied by SPSS statistical software and statistical analysis ANOVA tests. The results are in favor of formulations F1, F2 containing 20-30% Carbopol 71 and of 37- 47% Microcelac. **Keywords**: 5-FLUOROURACIL, VAGINAL TABLETS, BIOADHESIVE VAGINAL TABLETS

In a previous study (1) twelve original formulations of bioadhesive vaginal tablets containing 100 mg 5-FU/tablet were prepared (2). The concentrations of matrix-forming polymers (3.4), two cellulose derivatives of different viscosity, Metolose 90 SH 4000, Metolose 90 SH 100000, and two types of polyacrylates with different degree of cross linking, Carbopol 71 and Carbopol 974, varied for each series of formulations in the 20 to 50% range. The pharmacotechnical characterization of the bioadhesive vaginal tablets containing 5-FU was performed by determining their specific quality characteristics (5,6). The results reported by the authors show that they fall within the limits stipulated by the regulations in force (5,6).

For the optimization of the formulation we aimed at analyzing the influence of formulation factors, independent variables (Xi), on some quality parameters of hydro-

philic matrix tablets containing 5-FU, namely resistance (Y11), friability (Y22) and disintegration time (Y44).

The use of experimental design in the formulation of matrix tablets and formulation analysis based on these quality characteristics required by bioadhesive vaginal tablets allows ranking the importance of independent variables (Xi) in relation with their degree of influence on the dependent variables (Yi).

In this respect we used the specialized SPSS software and statistical analysis ANOVA tests that are highly flexible, allowing the study of factors with linear constraints in the setup, irregular experimental spacing, and qualitative factors (7,8).

MATERIAL AND METHODS

Materials

We analyzed twelve original formulations of bioadhesive vaginal tablets containing 100 mg 5-FU/tablet.

Method

For the study an experimental design with 5 variables and four levels was selected (tab.I). The statistic analysis were made using SPSS statistical software, and parametric statistical tests - ANOVA

TABLE I

Independent variables (formulation factors)

Independent factors	Symbol	Levels			
		0	1	2	3
Carbopol 71 G NF	X1	0	60	90	150
Carbopol 974 P NF	X2	0	60	90	150
M 4000	X3	0	60	90	150
M 100000	X4	0	60	90	150
Microcelac	X5	0	50	110	140

An experimental study on a system is characterized by a response Y (dependent variable) that varies depending on various factors Xi (independent variables).

RESULTS AND DISCUSSION

The original biomucoadhesive tablets containing 5-FU have the shape of a uniform disk, with entire edges, are flat, white, spotless, and odorless. Mass uniformity is bellow the ± 7.5% limit specified in the Romanian Pharmacopoeia for 300 mg tablets. The results of pharmacotechnical characterization (tab. II) show that the analyzed tablets are within the limits stipulated by the regulations in force for friability, disintegration time and mechanical strength.

The results obtained by the statistical processing of dependent variables show a normal distribution, Gauss curve, which allows the use of parametric tests for statistical processing (fig. 1).

a Dependent Variable: Y11

Independent variables X1-X4 had an insignificant ($p>0.05$) and negative influence (coefficient B) by diminishing mechanical strength, which technologically means that for obtaining tablets with adequate strength 20-30% of bioadhesive excipients should be used (tab. III, IV).

TABLE II

Matrix of experimental design responses

Parameters Formula	Y22 Friability%	Y11 Mechanical Strength(N)	Y44 Disintegration Time (min.)
F1	0.09	94.96	99
F2	0.16	92.52	165
F3	0.38	85.00	196
F4	0.61	60.56	76
F5	0.68	56.42	79
F6	0.72	52.16	67
F7	0.33	94.20	133
F8	0.20	100.92	158
F9	0.22	102.24	188
F10	0.28	100.15	141
F11	0.26	108.64	232
F12	0.25	111.38	282

		B	Std. Error	Beta		
1	(Constant)	636.523	362.629		1.755	.130
	X1	-2.514	1.791	-5.896	-1.404	.210
	X2	-2.903	2.033	-6.810	-1.428	.203
	X3	-2.484	1.791	-5.826	-1.387	.215
	X4	-2.447	1.791	-5.739	-1.366	.221
	X5	-3.004	1.847	-5.673	-1.627	.155

TABLE III
Influence of formulation factors on friability
Coefficients (a)

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	-.095	.107		-.890	.394
	X5	.004	.001	.808	4.339	.001

a Dependent Variable: Y22In the case of friability, dependent variable Y22, the regression model excluded from calculation the independed variables X1-X4, as they were insignificant, significance values p ≅ □, keeping only variable X5, Microcelac, that had a significant (p = 0.001) and positive influence (B=0.004), meaning that an increase in the amount of Microcelac also causes increased tablet friability

TABLE IV
Influence of formulation factors on disintegration time
Coefficients (a)

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	4046.764	634.386		6.379	.001
	X1	-18.749	3.133	-11.243	-5.985	.001
	X2	-21.543	3.557	-12.918	-6.057	.001
	X3	-18.559	3.133	-11.129	-5.924	.001
	X4	-17.931	3.133	-10.752	-5.723	.001
	X5	-20.460	3.231	-9.878	-6.333	.001

a Dependent Variable: Y44

The dependent variable Y44, disintegration time, is significantly influenced (p = 0.001) by independent variables X1-X5. The higher the percentage of mucoadhesive substance in the formulation the longer the duration of time the drug stays in contact with vaginal mucosa, long enough to produce its therapeutic effects.

CONCLUSIONS

Using the specialized *SPSS* statistical software and ANOVA we can say that the analyzed quality parameters, strength, friability and disintegration time are influenced by the nature of excipients and drug-excipient ratio, the best formulations being those containing 20-30% C71 and 37-47% Microcelac, formulations F1 and F2, respectively.

FERULIC ACID DERIVATIVES WITH INSECTICIDAL ACTIVITY

A recent study by Huang GY et al. showed that plant viruses cause many serious plant diseases and are currently suppressed with the simultaneous use of virucides and insecticides. The use of such materials, however, increases the amounts of pollutants in the environment. To reduce the environmental contaminants, virucides with insecticidal activity is an attractive option. A series of substituted ferulic acid amide derivatives and the corresponding hydrogenated ferulic acid amide derivatives were synthesized and evaluated for their antiviral and insecticidal activities. The majority of the synthesized compounds exhibited good levels of antiviral activity against the tobacco mosaic virus (TMV). Furthermore, the compounds displayed good insecticidal activities against insects with piercing-sucking mouthparts, which can spread plant viruses between and within crops. The bioassay showed that the compounds not only inhibited the plant viral infection, but also prevented the spread of plant virus by insect vectors. These findings therefore demonstrate that the ferulic acid amides represents a new template for future antiviral studies (Huang GY, Cui C, Wang ZP et al. Synthesis and characteristics of (Hydrogenated) ferulic acid derivatives as potential antiviral agents with insecticidal activity. Chemistry Central Journal 2013; 7:33 doi:10,1186/1752-153x-7-33).

2. National Institute for Research and Development in Microbiology and Immunology "Cantacuzino", National Reference Centre for Influenza

SEVERE ACUTE RESPIRATORY INFECTIONS SURVEILLANCE IN ROMANIA - IS IT ANY GAIN TO PUBLIC HEALTH? (Abstract): This article **aims** to present the operation and usefulness of severe acute respiratory infection (SARI) surveillance in Romania. **Material and methods** : The information obtained from surveillance data analysis using *EpiInfo* program revealed a greater severity of influenza in the second post-pandemic season (2011/2012) compared to the previous one (2010/2011). Detected risk factors were evidence-based arguments for recommending preventive measures in certain population groups. **Conclusions**: This surveillance system has proven useful, being able to provide information on the severity of influenza and other etiologies involved in severe acute respiratory infections.
Keywords: SURVEILLANCE, SEVERITY, RISK FACTORS

Hospital based sentinel surveillance for influenza severity was implemented during pandemy with the support of WHO-EURO. There has been no measure of severity until then. Severe Acute Respiratory Infections (SARI) Surveillance continued in the next two post-pandemic seasons, having as objectives to estimate SARI incidence in a catchment area, to describe the etiology of SARI cases and to evaluate underlying risk conditions, in order to recommend evidence based public health measures.

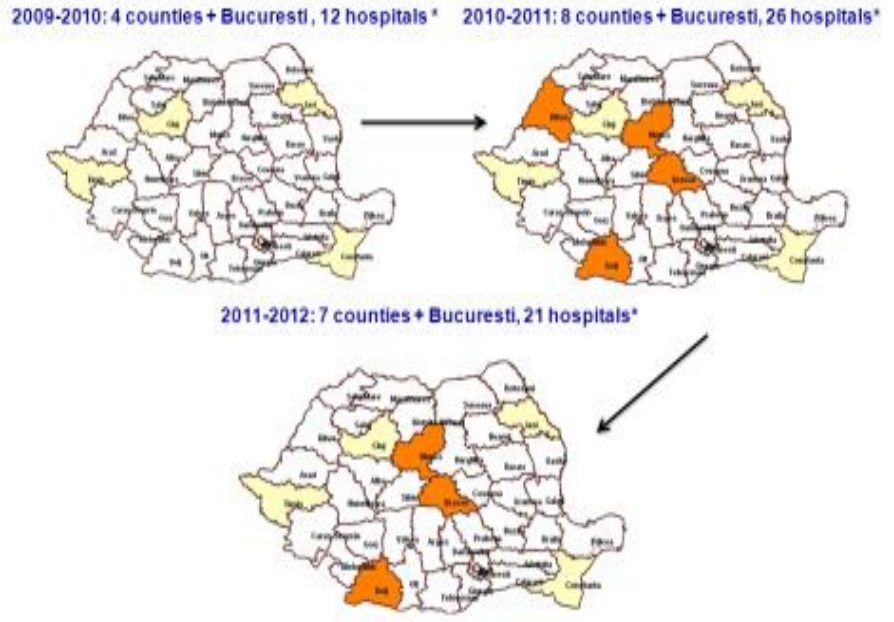
MATERIAL AND METHODS

System description. We used the WHO-EURO case definition for SARI (1, 2). We calculated a denominator based on the number of hospitalizations in the previous three years in each sentinel hospital after county of residence of the patient and the extent of each county in average admissions for three years was applied to county population. The sum of these populations was the population of the area of accessibility of the system ("catchment area"). For season 2010/2011 its value was 6,413,821, and for 2011/2012, were 5,813,728. Number of participating sentinel hospitals was changed over time (fig.1). The work began in four counties (Constanta, Cluj, Iasi, Timis) and Bucharest Municipality, out of 42 Romanian counties. In the first post-pandemic season (2010/2011) four counties were added (Bihor, Brasov, Dolj, Mures) and in the second (2011/2012) one of these (Bihor) was excluded due to lack of data.

Data were collected on a sheet of SARI surveillance case. Three levels of validation were used: the first was made by the hospital epidemiologist, the second by the epide-

miologist from County Public Health Authority and the third at national level - National Center for Communicable Disease Surveillance and Control (NCCDSC), where the SARI surveillance coordinator epidemiologist made final data validation and subsequent introduction the data in the national database. Weekly analysis of data was performed using *Epi Info* program and weekly information was posted on the NCCDSC site. Data for SARI cases were weekly loaded in the electronic platform TESSy (The European Surveillance System).

Because the case definition for SARI was changed in season 2011/2012, as recommended by WHO-EURO, updated in May 2011 (2), analytical results presented below will refer only to SARI cases with fever higher than or equal to 38 °C associated with coughing and shortness of breath or difficulty breathing, as signs and symptoms common to both case definitions.



*infectious diseases hospitals, pediatrics, pulmonology, emergency hospitals

Fig. 1. SARI sentinel, Romania, during pandemic and the first two post-pandemic seasons

A sampling algorithm was established and included in surveillance methodology. Before the onset of influenza season (week 10% positive samples for the same subtype / variant of the total number of those taken in the same week), samples from all SARI cases reported were identified and investigated for the etiology of influenza, and 25% of the negative (according to WHO recommendations), would be evaluated for other etiologies (RSV, hMPV, parainfluenza viruses, coronaviruses, *Str. pneumoniae*). After the onset of flu season, only one sample per week, taken from each sentinel hospital, the first case of SARI detected and reported, the etiology was investigated

only for influenza.

All deaths registered in possible (case that meets the clinical criteria), probable (case that meets the clinical criteria and has an epidemiological link to a laboratory confirmed case) or confirmed (case that meets the clinical criteria and is laboratory confirmed with influenza) SARI cases were to be reported immediately by telephone on CNSCBT and within 24 hours to be sent to the same destination the Sheet flu/ SARI death, by fax or e-mail

RESULTS

Epidemiological findings. In the second post-pandemic season (2011/2012) 346 SARI cases were validated (out of 349 reported), compared to 438 (out of 449) in the previous season.

SARI incidence decreased from 6.06‰ in 2010/2011, to 5.41‰ in 2011/2012. Graph representing the weekly incidence rates (fig. 2) shows two peaks in weeks 5 and 9 of season 2010/2011. In 2011/2012, two peaks, but having lower amplitude, were recorded in weeks 4 and 6.

Male / female ratio (M / F) was almost equal in the two seasons (1.1 in 2010/2011, 1.2 in 2011/2012). The median age was lower in 2011/2012, for SARI cases in general, and also for those influenza virus type A confirmed (tab. I, II).

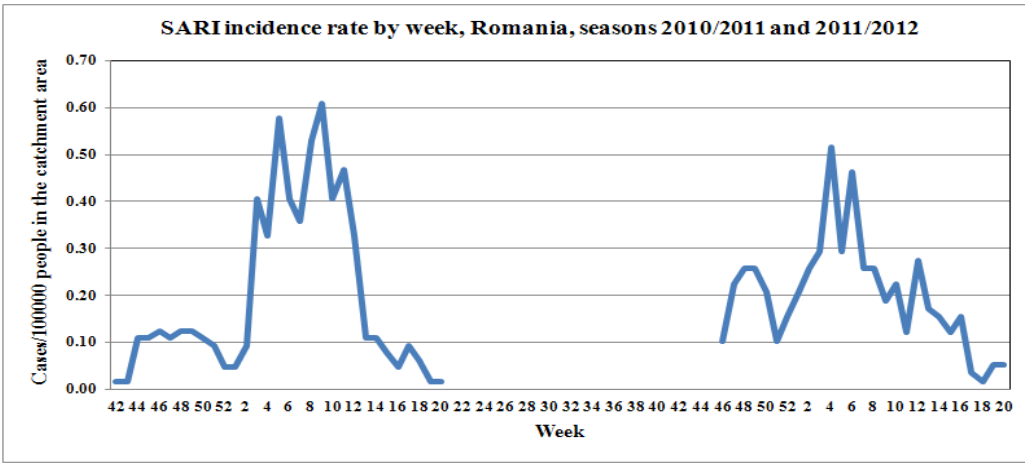


Fig. 2. SARI incidence rate by week, Romania, season 2010/2011 and 2011/2012

TABLE I

Median age in SARI cases and SARI cases confirmed with influenza, in the first post-pandemic season (2010/2011), Romania

Median age (years)	SARI overall (N=389)	SARI confirmed with A/H1N1 (N=75)	SARI confirmed with B (N=74)
Cases	**21** (0-86)	**33** (0-82)	11 (0-82)
Deaths	37 (15-79)	31 (15-61)	73 (37-77)

TABLE II

Median age in SARI cases and SARI cases confirmed with influenza, in the second post- pandemic season (2011/2012), Romania

Median age (years)	SARI overall (N=315)	SARI confirmed with A/H3N2 (N=62)	SARI confirmed with B (N=1)
Cases	**3** (0-88)	**26** (0-88)	49 (N=1)
Deaths	11 (1-83)	1 (N=1)	NA (N=0)

Analysis by age distribution of SARI cases and confirmed SARI cases showed that while in season 2010/2011 most SARI cases and also A/H1N1 confirmed SARI cases have been registered to the same group age, 15-49 years, in 2011/2012 most cases registered were children, but the highest A/H3 positivity rate was recorded in the age group ≥ 65 years.

Laboratory findings. In season 2010/2011, laboratory investigations were performed for 378 cases of SARI (97.2%), with an overall positivity rate of 51.3% and 39.7% for influenza. In 2011/2012, 263 cases with SARI were investigated in laboratory (83.5%). The overall positivity rate was higher than the previous season (65.8%), but lower for influenza (24%). In 2010/2011, the first week SARI surveillance detections were dominated by Respiratory Syncytial Virus (RSV). A/H1N1 influenza virus was detected and became dominant between weeks 4 and 7 (late January-early weeks of February 2011). Influenza B was more frequently detected between weeks 8 and 12 (end of February to end of March 2011). In 2011/2012, the first weeks of monitoring were dominated by parainfluenza virus detections (PIV). Then RSV was detected (November 2010), co-existing with A/H3 influenza virus from week 52 (late December). A/H3 influenza virus detections have become dominant since week 5 (early February) (fig. 3). Starting with week 6, laboratory investigations were detected only for influenza etiology, as mentioned in surveillance methodology. Testing for other etiologies have been claimed and paid by the County Public Health Authorities.

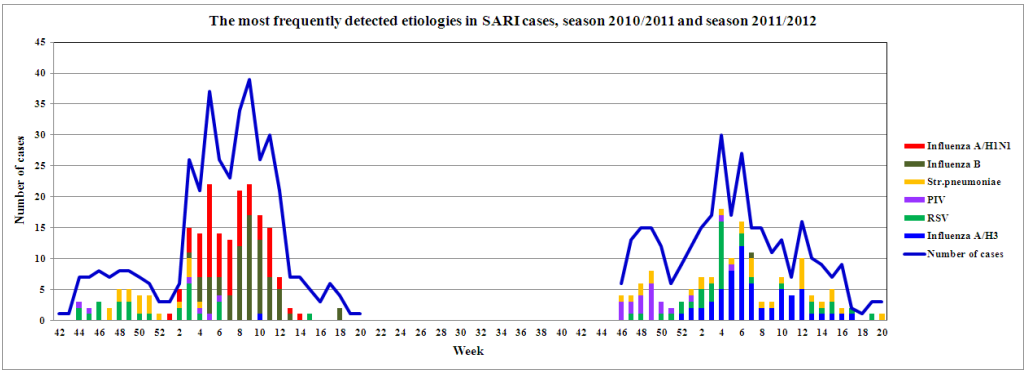

Fig. 3. The most frequently detected etiologies in SARI cases, season 2010/2011 and season 2011/2012

Comparing the distribution of various etiologies detected in SARI cases in the first two post-pandemic seasons (fig. 4), we observed equal proportions of influenza A/H1N1 and influenza B (37%) in 2010/2011, while the A/H3N2 represented only 1%. In 2011/2012, the highest proportion (42%) was recorded for influenza A/H3N2. Influenza B attended only 1%. Unlike other European countries (3) A/H1N1 pandemic virus was not detected in any SARI case. Other etiologies were represented by RSV, parainfluenza viruses and *Str. pneumoniae*. The National Reference Laboratory for Influenza in National Institute for Research and Development in Microbiology and Immunology (NIRDMI) "Cantacuzino" also detected hMPV, Bocavirus, Adenovirus, *H. influenzae*, parainfluenzae, but in smaller proportions.

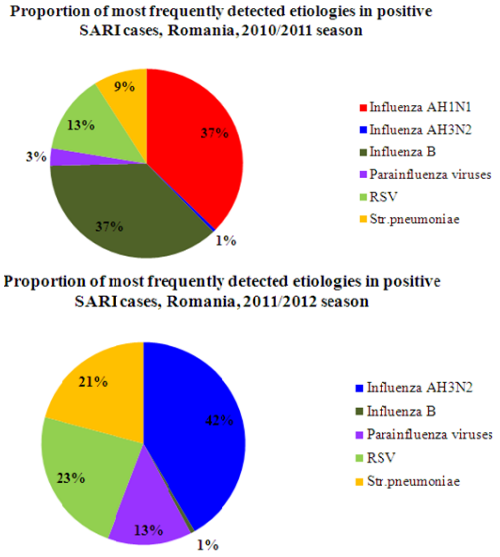

Fig. 4 Etiological distribution in positive SARI cases in the first two post pandemic seasons, Romania

For 2010/2011 season, the National Reference Laboratory for Influenza communicated to NCCDSC 9 isolations and sequencing in SARI cases: 5 A/H1N1/ California/7/09-like, 1 A/ H3N2/Victoria/ 210/09- like and 3 B/Brisbane/60/08-like. Eight antiviral sensitivity tests have been performed, 7 strains being sensitive for Oseltamivir and one with uncertain result. For 2011/2012 season, 14 isolations in SARI cases have been communicated for A/H3N2-A/Perth/16/2009 like and 8 sequencing in confirmed A/H3N2 SARI cases (13%): 4 Clade A/Victoria/208, group 6; 3 - Clade A/Victoria/208, group 3C and 1 - Clade A/Victoria/208, group 3A. Fourteen antiviral sensitivity tests have been performed, all the strains being sensitive for Oseltamivir and Zanamivir.

Comparison for complications. The proportion of complications in the second post pandemic season (2011/2012) was lower compared to 2010/2011, both in SARI cases overall and in SARI confirmed with influenza type A. We also found lower proportion for ARDS and the same discrepancy between ARDS and ventilation. This suggests that the severity of ARDS was not as high, but, on the other hand, it is possible that the data were not very well updated. A very low number of deaths in SARI cases (6) was registered in 2011/2012, compared to the previous season (27), and just one out of 6 was confirmed with influenza A/H3N2 (a 21 month old, immune-compromised girl), compared to 19 in 2010/2011, most of them caused by A/H1N1.

A lower proportion of SARI cases were admitted in ICUs in 2011/2012, compared to the previous season, both in SARI overall (14.9% *vs.* 36.2%) and in SARI confirmed with influenza (9.5% *vs.* 34%).

The proportion of SARI cases with secondary bacterial pneumonia increased from 26.5% in 2010/2011 (103 cases), to 29.8% in 2011/2012 (94 cases). Only 2 cases out of

103 were positive for *Str. pneumoniae* in 2010/2011 and none of the 94 cases in 2011/2012. We also observed an increase in the proportion of SARI cases positive for *Str. pneumoniae* in 2011/2012 (9.8%), compared to the previous season (4.6%). For 30.7% A/H1N1 confirmed SARI cases (23) and for 24.3% B confirmed SARI cases (18) a secondary bacterial pneumonia was mentioned in 2010/2011, while in the next season the value for A/H3 confirmed SARI cases with secondary bacterial pneumonia (22) was higher (35.5%). None of the A/H1N1 and B confirmed SARI cases in 2010/2011 and none of the A/H3 confirmed SARI cases in 2011/2012 was positive for *Str. pneumoniae*.

Comparison for seasonal vaccination. The proportion of vaccinated SARI cases was very low in both seasons: 2.3% in 2010/2011 and 1% in 2011/2012. This fact illustrates the low vaccination coverage in general population: 6% in the first post-pandemic season and 3% in the second one. Just one A/H1N1 and one B confirmed SARI case had been vaccinated against influenza. None of SARI cases confirmed with influenza A/H3 or B in 2011/2012 had been vaccinated.

Comparison for risk factors. For 2010/2011, we found as significant risk factors for A/H1N1 confirmed SARI cases (95% CI), obesity for total cases, chronic kidney disease for female and obesity and compromised immunity for male (tab. III).

For 2011/2012, we found chronic heart diseases and compromised immunity as significant risk factors for total A/H3 confirmed SARI cases (95% CI), the same for female and, additionally, pregnancy for childbearing age female (15-45 years old). No risk factor was found for male (tab. IV).

TABLE III

Significant risk factors in A/H1N1 confirmed SARI cases, Romania, 2010/2011 season

RISK FACTOR	TOTAL

DISCUSSION

Before 2009 pandemy, many discussions and debates were held on influenza severity and on a possible dedicated surveillance system. From the proposed models, we chose and implemented the classic SARI Surveillance. Like any other case based surveillance system, SARI Surveillance is very time consuming and also resource consuming, in terms of staff and finance for laboratory investigations.

All the above-mentioned analysis and comparison between seasons refer only to SARI cases having fever of ≥ 38°C, associated with cough, and shortness of breath or difficulty breathing. This approach changed the logistic regression results for 2010/2011, when another case definition was in place. At that time, we found some additional significant risk factors for A/H1N1 confirmed SARI cases (95% CI) in female: obesity, chronic liver disease, and pregnancy (the last, in childbearing age female).

To improve surveillance, the discussions continue in our team about the involvement of *Str. pneumoniae* in SARI cases etiology. Many cases detected positive could be, in fact, just carriers, given that for most of them the sample was represented by a nasal and pharyngeal swab and not by tracheo-bronchial aspirate.

CONCLUSIONS

We find this surveillance system useful because it is capable to provide information about influenza severity and about the involvement of other etiologies in severe acute respiratory infections. We found a lower severity of influenza in the second post-pandemic season compared to the previous one, suggesting that influenza A/H3N2 was less aggressive than A/H1N1. The underlying risk conditions are evidence based arguments to issue recommendations for influenza prevention in certain risk groups.

We consider that the case based sentinel SARI Surveillance must to continue, and to explore influenza and, depending on resources, other etiologies in SARI cases: at least RSV in children and elder people and *Str. pneumoniae* in cases with secondary bacterial pneumonia. We chose these two etiologies because specific preventive measures (specific immunoglobulin and a vaccine, respectively) could be targeted to certain risk groups.

ACKNOWLEDGEMENTS

We present our acknowledgements to all the clinicians, epidemiologists, microbiologists, nurses and statisticians involved in SARI Surveillance in Romania.

PROFESSIONAL AND MANAGEMENT ISSUES IN THE SURVEY AND CONTROL OF NOSOCOMIAL INFECTIONS IN GENERAL SURGERY HOSPITALS (Abstract): Nosocomial infections (NI) are evidenced in health care facilities around the world as representing the main health and mortality problem in the assisted patients. This prompts for the constant monitoring of NI and implementing preventive and control measures. We designed and administered a 10-item questionnaire referring to NI to the health care personnel of two general surgery units from municipal two hospitals (A and B). The results proved to be poor, especially for hospital B. We investigated the measures against the sources of infection, pathogen carriers and ways of transmission, as well as the management of patients with increased susceptibility to NI. The use of antibiotics and disinfectants was also studied. **Key words:** NOSOCOMIAL INFECTIONS, QUESTIONNAIRE, SURGERY HOSPITAL.

Nosocomial infections have a special place in human pathology, being considered a major population health issue for all the health care units (1, 2 , 3, 4). NI are characterized by a high incidence and severe clinical and functional consequences that lead directly or indirectly to the abrupt increase of treatment costs and cause economic, moral and social damage.

Postoperative infectious complications with septic-purulent clinical pictures do not only lead to avoidable unnecessary suffering, but also prolong the hospital stay from 5.6 to 35.4 days, depending on the unit profile, a mean increase of 14.07 days (5,4,6,7), plus also great economic loss.

MATERIAL AND METHODS

a. A questionnaire containing 10 questions (Annex I) was designed and administered to the health care personnel of two general surgery units – from hospital A and B respectively – in order to assess the level of professional information required for the awareness, prevention and control of NI.

b. We studied the measures taken against the infection sources identified by clinical and laboratory check-up of the personnel (in years 2007 and 2010), as well as the attitude towards the pathogens carriers.

c. The measures taken against the ways of transmission were studied by assessing the control of septic and aseptic routes,

current and final disinfection, aseptic techniques and sterilization of equipment.

d. We surveyed the measures taken in the case of patients with high risk of NI.

e. We surveyed the use of antibiotics and disinfectants

RESULTS

a. Forty (40) questionnaires were administered in hospital A and 25 in hospital B, to the nurses and patient caretakers of the two general surgery units (tab. 1)

TABLE I

Hospital	0	Nurse / Caretaker	1	Nurse / Caretaker	4	Nurse / Caretaker	5	Nurse / Caretaker	6	Nurse / Caretaker
A	80 %	62,5 % / 37,5 %	20 %	75 % / 25 %	0 %		0 %		0 %	
B	0 %		0 %		16 %	100 %	80 %	45 % / 55 %	4 %	100 %

Legend: A – hospital A, B- hospital B; 0-correctly filled in questionnaire; 1,4,5,6 – Wrong answers

b. In hospital B clinical and laboratory examinations were performed in 40 health care personnel members from the surgical unit and 40 from the operating block in the years 2007 and 2010.

In the surgical unit there were two documented cases of healthy HBsAg carriers, one nurse diagnosed in 2010 and a stretch carrier diagnosed when hired, in 2007; both individuals were under hepatoprotective therapy.

There were 3 cases of healthy HBsAg carriers in the operating block (one nurse and two caretakers), diagnosed in 2007, under hepatoprotective therapy, as well as two cases of HCV (caretakers) diagnosed in 2010, under Interferon therapy. In none of the above 7 cases could the infection source be identified.

In hospital A 34 personnel members of the surgical unit and 16 from the operating block underwent clinical and laboratory examinations in 2010, 100% were clinically healthy, with negative tests for HBsAg, HCV-Ab, anti-HIV Ab, VDRL.

In 2007 clinical and laboratory examinations were performed in only 12% of personnel, all being healthy and negative for HBsAg, HCV-Ab, anti-HIV Ab, VDRL.

c. Surgery units from hospital A and B are on the last floor of the building, have a good connection with the hospital patient reception, the operating block, the ICU, sterilization services, personnel rooms, dining rooms, bathrooms, storage rooms.

Patient wards in both hospitals were divided into septic and a septic. The rooms are large enough for patient stretchers and wheelchairs. Beds allow access to the patient from three sides and are equipped with signaling systems.

Wound care wards included a gynaecological table, dressing cart, cupboards for instruments, sterile and non-sterile material, antiseptic solutions.

The operating blocks in the two hospitals included several operating rooms and annexes, directly linked to the ICU wards. They are isolated from circulation, access being through a buffer room and with strict observance of asepsis and anti-sepsis rules.

Current and final disinfection in the two sections use disinfectants approved by the Ministry of Health, in the recommended concentrations.

The following are used:

BICLOSOL – chlorine disinfectatnt for surfaces, drinking water, dishes, linen and clothing.

CIDEX OPA – high level disinfectant used especially for endoscopic equipment

THOR – used for surfaces, thermo-sensitive equipment, metallic instruments, pre-disinfection of instruments before sterilization, textiles

TERRALIN protect – used for the disinfection of medical devices, surfaces, sensitive materials

SUPRASEPT – high level disinfectant, used for thermo-sensitive materials, metallic instruments, medical devices, surfaces

MIKROYD AF Liquid – rapid spray disinfectant

MEDICARINE – chlorine tablets – used for washable surfaces, various objects, equipment, toilets and bathrooms

The health care personnel performing the disinfection took into account the resistance to disinfectants, the factors influencing disinfection, observed the general disinfection practice rules and the methods of application of chemical disinfectants according to the object treated.

Instruments of the two surgical units were sterilized using devices approved by the national health authority (Ministry of Health). Instructions for used were displayed visibly for every sterilizer.

Health care personnel affirmatively observed aseptic techniques, correct use of protection equipment and accessories (gloves, masks, eyeglasses, gowns), the operative preparation of the skin, the mucosa and/or clothing following contamination with biological fluids, the prevention of infection transmission through contaminated instruments, prevention of open wounds and mucosal membranes exposure, prevention of skin injury by needles or sharp instruments.

d. The measures taken in the case of patients more susceptible to NI were focused on isolation, increase of general body resistance, chemoprophylaxis and artificial immunization in certain cases; overall the measures were modest. The main emphasis in the daily activity was on the diagnosis and performance of the surgical act.

e. In both hospitals the main measure taken against NI prevention was antibiotic therapy. The frequency of active NI cases evidenced retrospectively by studying the records over a period of 8 months was 9.34% (A) and 9.60% (B) respectively, as compared to a reported frequency of 0.88% in hospital A and 0% in hospital B.

Antibiotic therapy in hospital A was prescribed in 62.83% of the cases as monotherapy, 28.3% as antibiotic associations, while in 8.84% no antibiotics were prescribed in the hospital. We could not document whether antibiotics were prescribed and bought by the patients themselves.

In hospital B 35.21% of NI cases were treated with monotherapy, 64.78% with drug associations and in 4.22% no antibiotics were prescribed in the hospital. Nor in this case could we document whether antibiotics were prescribed and bought by the patients themselves.

DISCUSSION

Results obtained after distributing the questionnaire to members of the health care personnel, especially those in the surgery unit of hospital B, revealed considerable problems regarding the professional knowledge necessary for NI prevention and control.

It is more than imperative to develop continuous training programmes for the health care personnel, with full responsibility and adoption by the medical staff of the adequate prophylactic practices, for applying the NI prevention measures and evaluating their efficiency (8, 9, 10, 11).

Nosocomial transmission can be reduced by application of standard prevention measures and patient confinement, taking into account the transmission channel of the infectious agents in a hospital environment (12, 13).

Hygiene of the hands remains the essential element of standard prevention measures and the most important method in the practical activity for reducing nosocomial transmission of infectious agents (13, 14, 15). Scientific motives, indications, methods and products used for hand hygiene are extremely well known (16-24) and observing this professional behavioural act is above all discussion.

All health care, clinical and laboratory personnel must be submitted to more rigorous and thorough controls, taking into account that hepatitis B and C viruses as well as HIV transmission are of utmost importance both for the personnel and patient health, because of the severity of late consequences of persistent infections and the limitations of the current treatment methods (25). Exposure to these germs must be considered – according to law - a medical emergency, for which immediate measures are required in order to prevent the spreading of the infection (26, 25, 27).

Antibiotics should not replace real and effective prevention and control measures of NI. Misuse of antibiotics explains but does not justify why infectious agents become more and more resistant to antibiotics. More and more frequently we witness the decision of clinicians to use reserve antibiotics in the treatment of infections, composite drugs which are considerably more expensive and which increase costs involved in patient treatment (28,29,30,31, 32,33,34), without addressing the functional deficiencies of the hospital and the professional staff deficiencies.

CONCLUSIONS

Knowledge of the fundamental principles of NI monitoring, prevention and control is undoubtedly deficient and explains both the underreporting of NI, as well as its real frequency, which is significantly higher than the one found in official accounts.

Learning and correctly applying the NI prevention measures by the health care personnel during medical assistance is axiomatic and can improve the quality of NI control.

Empirical “protective” antibiotic treatment, clearly expensive and unnecessary, must be avoided and its indications should be updated.

THE DEVELOPMENT AND VALIDATION OF A GC – MS METHOD FOR NICOTINE DETERMINATION FROM TOBACCO (Abstract): A gas chromatographic - mass spectrometric method (GC/MS) for determination of nicotine from tobacco products was developed and validated. **Material and method:** It was used an Agilent Technologies 7890A Chromatograph equipped with a DB 5 MS column (30 m x 0.25 mm, 0.25 µm) and Agilent Technologies 5975C inert MSD detector. The temperature program began from 100˚C and increase with 10˚C/min to 190˚C than with 20˚C/min to 280˚C, constant for 5 min, with He as carrier gas (1 ml/min) and MS detection. The temperature of the source was 230˚C and the temperature of the quadrupole was 150˚C. The parameters of validation were studied according to the international requirements. **Results:** Finally, the method established has following parameters: is linear in the 1.01-201.8 µg/ml range, has the detection limit of 3.6 µg/ml, the quantification limit of 10.8 µg/ml, is precise (RSD < 5%, n=9) and accurate (mean recovery is 100.28% in 99.08 – 100.96 µg/ml range). **Conclusion:** The method can be used to determine nicotine from tobacco products, with good results. **Key words**: NICOTINE, GC-MS, VALIDATION

Nicotina este principalul alcaloid extras din frunzele de tutun, *Nicotiana tabacum*, familia *Solanaceae*. Tutunul uscat din care se obțin țigaretele, țigările de foi şi tutunul de pipă, are o compoziție chimică complexă, conținând nicotină, alături de alți alcaloizi secundari, acizi organici, hidrați de carbon, rezine, uleiuri eterice, enzime, alți compuşi. Țigareta se poate asemăna cu o retortă chimică, fumul de tutun rezultat din arderea unei țigarete conținând 4.000 de compuşi, dintre care peste 60 de substanțe au potențial cancerigen.

Consumul cronic de tutun, respectiv tabagismul sau nicotinismul, considerat prima cauză de mortalitate prematură şi morbiditate evitabilă, a atins astăzi amploarea unei "epidemii mondiale", deoarece, conform statisticilor OMS, numărul fumătorilor la scară planetară se cifrează la aproximativ 1,1 miliarde. În ultimele decenii, tutunul nu mai este considerat un produs care dăunează sănătății, ci ca un produs care curmă viața. Statistic, după OMS, tabagismul produce la nivel mondial, în fiecare oră, 560 de decese (134.000 pe zi; 4,9 milioane pe an) (1). Tabagismul poate fi definit ca un comportament susținut de o dependență farmacolo-

gică faţă de nicotină, intoxicaţia tabagică fiind cea mai răspândită dintre toate toxicomaniile cunoscute în prezent. Fumatul reprezintă una din cele mai grave şi complexe probleme de sănătate publică, prin efectele provocate asupra organismului.

Nicotina, responsabilă de dependenţa tabagică, acţionează asemănător acidului cianhidric, absorbţia sa fiind foarte rapidă la nivelul tuturor mucoaselor. Doza letală la om este de 60 mg. Produce dependenţă de 6-8 ori mai mare decât alcoolul, dar la fel de mare ca şi cocaina, 95-100% dintre fumători fiind dependenţi. Acţiunea toxică a nicotinei se manifestă la nivelul sistemului nervos central, la nivelul aparatului cardiovascular, respirator, tubului digestiv; afectează metabolismul glucidic, lipidic, proteic (2).

În lucrarea de faţă ne-am propus elaborarea şi validarea unei metode simple şi rapide de determinare, prin cromatografie de gaze cuplată cu spectrometria de masă (GC – MS), a nicotinei din tutun.

MATERIAL ŞI METODĂ

Reactivi şi aparatură. S-a utilizat un cromatograf de gaze Agilent Technologies 7890 A, injector Agilent Technologies 7683 B Series şi detector spectrometru de masă Agilent Technologies 5975C inert MSD.

Reactivii utilizaţi (metanol şi diclormetan) sunt de puritate cromatografică, iar etalonul de nicotină a fost procurat de la firma Merck (densitate 1,009 g/ml). Soluţia stoc de nicotină, de concentraţie de 200 μg/ml, a fost preparată în amestec metanol / diclormetan (1/1, v/v).

Condiţii cromatografice. Analiza a fost efectuată pe o coloană capilară DB 5 MS (30 m x 0,25 mm; 0,25 μm) cu o fază mobilă formată din heliu (debit 1 ml/min); temperatura injectorului = 250°C, temperatura sursei MSD = 230°C, temperatura cvadrupolului = 150°C, gradient de temperatură în compartimentul coloanei (10°C/min între 100 - 190°C, 20°C/min între 190 - 280°C, constant 5 min); volumul injectat = 0,3 μl în modul SPLIT (1 / 10). Achiziţia s-a efectuat în modul SCAN (10 – 450 UAM). Soft utilizat: Chemstation, Agilent Techologies.

Soluţii standard. Soluţiile standard de nicotină au fost preparate în amestec metanol / diclormetan (1/1, v/v), în domeniul de concentraţie 1,01 – 201,8 μg/ml.

REZULTATE ŞI DISCUŢII

Identificarea nicotinei din probele analizate s-a realizat pe baza comparării timpului de retenţie şi al spectrului de masă înregistrat în vârful acestuia, din cromatograma probelor, cu timpul de retenţie al picului corespunzător nicotinei din cromatograma unei soluţii standard conţinând nicotină, şi cu spectrele de masă din biblioteca spectrală Willey (3).

Validarea metodei. Pentru validarea metodei de determinare a nicotinei prin cromatografie de gaze cuplată cu spectrometrie de masă, au fost urmăriţi următorii parametri: liniaritatea, limita de detecţie, limita de cuantificare, precizia (precizia sistemului, precizia metodei, precizia intermediară) şi exactitatea. Toate testele de validare au fost efectuate în conformitate cu cerinţele internaţionale în vigoare (4-9).

Liniaritatea. Pentru studiul liniarităţii, pornind de la soluţia stoc de nicotină (201,8 μg/ml) au fost preparate un număr de 3 seturi de soluţii de lucru, în domeniul de concentraţie 1,01 – 201,80 μg/ml. Pentru fiecare soluţie în parte s-au efectuat analizele în conformitate cu modul descris, s-au înregistrat cromatogramele şi s-au calculat ariile picurilor corespunzătoare nicotinei. Valoarea medie calculată (tab. I) s-a reprezentat grafic în funcţie de concentraţie (fig. 1).

TABELUL I

Ariile picurilor obținute în cazul studiului liniarității metodei de determinare a nicotinei prin GC-MS

Nr. det.	Nicotină µg/ml	Arie pic

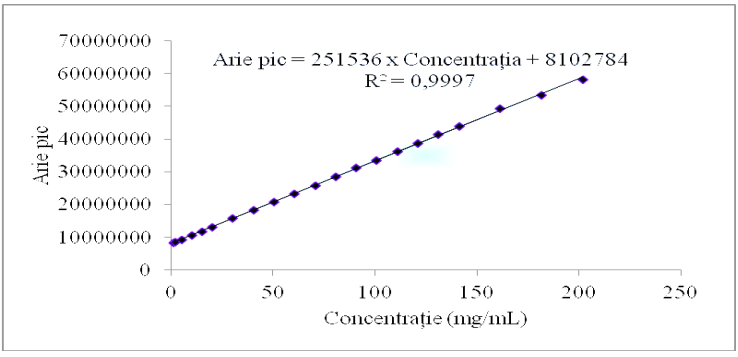

Fig. 1. Dreapta de calibrare pentru determinarea nicotinei prin GC-MS

S-a calculat ecuația şi eroarea standard a dreptei de regresie, precum şi coeficientul de regresie (R^2). Astfel, ecuația dreptei de calibrare este:

$$Arie\ pic = 251535{,}6 \times Concentrația\ (\mu g/ml) + 8102784$$

Valorile calculate pentru eroarea standard a dreptei de regresie (SE) este 271159,5, iar pentru coeficientul de regresie (r^2) este 0,9997.

Din datele prezentate rezultă că metoda de determinare a nicotinei prin GC-MS este liniară pe domeniul de concentraţie studiat.

Folosind parametrii statistici calculaţi (eroarea standard şi panta dreptei de regresie), s-au calculat limita de detecţie (LD) şi limita de cuantificare (LQ), utilizând relaţiile:

$$LD = \frac{3,3 \cdot SE}{\text{Panta}} = \frac{3,3 \cdot 271159,5}{251535,6} = 3,6 \mu g / mL \quad ; \quad LQ = \frac{10 \cdot SE}{\text{Panta}} = \frac{10 \cdot 271159,5}{251535,6} = 10,8 \mu g / mL$$

Precizia. Pentru determinarea preciziei, s-au studiat precizia sistemului, precizia metodei şi precizia intermediară.

Pentru determinarea preciziei sistemului sau a repetabilităţii injecţiei, aceeaşi soluţie conţinând nicotină, în concentraţie de 100,9 μg/ml, a fost analizată de 10 ori, în aceleaşi condiţii de operare. Rezultatele experimentale şi calculul statistic s-a realizat pe baza deviaţiei standard – SD şi a deviaţiei standard relativă – RSD % (tab. II).

Pentru determinarea preciziei metodei, s-au efectuat câte trei determinări pe soluţii diferite, aflate la trei nivele de concentraţie (100 μg/ml ± 30%). Pentru toate cele nouă cromatograme obţinute, s-a calculat aria picului corespunzător nicotinei şi (pe baza ecuaţiei dreptei de regresie) concentraţia reală din probă (tab. III).

9		41413721	132,43	100,96
Date statistice			**Media (%)**	**100,42**
			SD	**0,6590**
			RSD (%)	**0,6562**

Pentru determinarea preciziei intermediare, s-au efectuat câte trei determinări pe soluții diferite aflate la trei nivele de concentrație (100 μg/ml ± 30%). Pentru toate cele nouă cromatograme obținute, s-a calculat aria picului corespunzător nicotinei şi (pe baza ecuației dreptei de regresie) concentrația reală din probă (tab. IV).

TABELUL IV

Precizia intermediară pentru determinarea nicotinei prin GC-MS

Nr. det.	**Concentrație teoretică (μg/ml)**	**Arie pic**	**Concentrație calculată (μg/ml)**	**%**
1	70,63	25764109	70,21	99,41
2		25732428	70,09	99,23
3		25939261	70,91	100,40
4	100,90	33456945	100,80	99,90
5		33752212	101,97	101,06
6		33574085	101,26	100,36
7	131,17	41414853	132,43	100,96
8		41432299	132,50	101,02
9		41426742	132,48	101,00
Date statistice			**Media (%)**	**100,37**
			SD	**0,7147**
			RSD (%)	**0,7121**

În urma prelucrării statistice a datelor experimentale obținute (tabelele II, III, IV), se constată că valorile RSD sunt mult mai mici decât limita maximă admisă de 5%, de unde rezultă că metoda de determinare a nicotinei prin GC – MS este precisă.

Exactitatea. *Pentru determinarea exactității metodei*, s-au efectuat câte trei determinări prin metoda adausului de soluții diferite aflate la trei nivele de concentrație (100 μg/ml ± 30%). Pentru toate cele nouă cromatograme obținute, s-a calculat aria picului corespunzător nicotinei şi (pe baza ecuației dreptei de regresie) concentrația reală din probă. S-a calculat regăsirea medie, minimă şi maximă (tab. V).

TABELUL V

Exactitatea metodei de determinare a nicotinei prin GC-MS

Nr. det.	Concentrație teoretică (μg/ml)	Arie pic	Concentrație calculată (μg/ml)	Regăsire (%)

9		41329236	132,09	100,70
Date statistice			**Regăsire medie**	**100,28**
			Minim	**99,08**
			Maxim	**100,96**

Din datele experimentale obținute, s-a constatat că valorile medii (100,28%) se încadrează în limitele admise (± 5÷10%), ceea ce confirmă că metoda de determinare a nicotinei prin GC – MS este exactă.

Pentru aplicarea în practică a metodei dezvoltate şi validate, s-au preparat probe de tutun provenind din țigări aflate în rețeaua comercială a municipiului Iaşi (Marlboro şi Kent). Astfel, nicotina a fost extrasă din tutun, cu amestec metanol / diclormetan (1/1, v/v), şi determinată prin GC – MS, în condițiile metodei. Din datele experimentale obținute, s-a constatat faptul că, în probele de tutun analizate, cantitatea de nicotină este în limitele specificate.

CONCLUZII

Constatările noastre au permis elaborarea şi validarea unei metode de determinare cantitativă a nicotinei prin GC-MS, stabilindu-se condițiile de lucru: coloană cromatografică, regimuri termice, cantitatea de probă analizată, modul de identificare a nicotinei, liniaritatea dreptei de calibrare, limita de detecție, limita de cuantificare, precizia (precizia sistemului, precizia metodei, precizia intermediară) şi exactitatea. Rezultatele experimentale obținute arată că metoda este liniară (r^2 = 0,9997) pe domeniul de concentrații studiat (1 – 200 μg/ml), este sensibilă (LD = 3,6 μg/ml, LQ = 10,8 μg/ml), precisă (RSD < 5%, n = 9) şi exactă (regăsire medie = 100,28%). Metoda a fost aplicată cu rezultate bune pentru determinarea nicotinei din tutunul utilizat la prepararea țigărilor comerciale.

RELASHIONSHIP BETWEEN MATERNAL EDUCATIONAL LEVEL AND CHILD FEEDING IN A SERIES OF PRESCHOOL CHILDREN IN BACĂU TOWN. (Abstract): Child growth and development are decisively influensed by feeding. This depends on parent's financial resources and food habits, most often tradition-related. **Aim:** to determine how important mother's educational level is in this respect. **Material and methods:** the study was carried out on a series of 153 preschool children from two kindergartens in Bacău town. Their parents filled out a questionnaire on the frequency of weekly food consumption. **Results:** 64.5 %of the mothers of the children included in this study had a higher education. Most children had milk 4-7 times a week, cheese 2-3 times a week, eggs and chicken 2-3 times a week, and fruits 4-7 times a week. The diffrences in feeding provided by mothers with higher education and those less educated were statistically insignificant, food habits being quite similar. **Conclusions:** A good knowledge of food habits in a poplation is essential for developing programs aimed at changing the unhealthy ones. **Key words:** FOOD INTAKE, MATERNAL EDUCATIONAL LEVEL, FOOD HABITS

Creşterea şi dezvoltarea sunt două procese ce caracterizează copilăria şi adolescența şi care sunt influențate de ereditate şi particularitățile mediului fizic extern. În cel din urmă, alimentația joacă un rol hotărâtor în asigurarea normalității creşterii/dezvoltării copiilor cu dependență puternică de nivelul socio-economic al familiei şi cel de instruire al părinților. Nivelul superior de instruire al părinților poate asigura o alimentație adaptată necesităților particulare fiecărei etape de dezvoltare a copilului (1,2). Deşi comportamentele nutriționale se transmit de la o generație la alta este importantă intervenția, prin mijloace educaționale, pentru a asigura o alimentație optimă, cantitativ şi calitativ, îndeosebi, în perioada de preşcolar, etapă în care obiceiurile alimentare se formează şi pot fi modelate cu uşurință, prin intermediul colegilor şi educatorilor, care, în mod frecvent, constituie un model pe care copilul îl respectă şi îl urmează cu multă încredere. În acest context, colaborarea între familie, medici şi educatori este împortantă, în direcția implementării unor programe naționale de îmbunătățire cantitativă şi calitativă a alimentației (3, 4, 5).

MATERIAL ŞI METODE

Studiul s-a realizat pe un lot de 155 preşcolari, proveniți de la două grădinițe din

oraşul Bacău. Informaţiile au fost acumulate pe baza unei fişe de anchetă epidemiologică cu referire la studiile mamei, modul de alimentaţie zilnică a copiilor, cu aprecierea obiceiurilor alimentare în relaţie cu zona geografică respectivă, cu accent pe consumul săptămânal de produse lactate, carne şi preparate din carne, peşte, ouă, grăsimi, derivate de cereale, legume, fructe şi produse zaharoase (6, 7).

Prelucrarea şi evaluarea datelor s-a realizat prin metode epidemiologice clasice şi statistico-matematice, îndeosebi testul Pearson.

REZULTATE ŞI DISCUŢII

1. Nivelul educaţional al părinţilor şi comportamentele alimentare

Cercetările noastre au evidenţiat faptul că mamele cu studii superioare deţin multe informaţii legate de aspectele de sănătate şi cele educaţionale, insistând asupra aspectelor formative importante, la vârsta preşcolară. Chiar dacă, în unele cazuri, nivelul economic al familiei era modest, mamele reuşesc să asigure o alimentaţie adecvată copilului, adesea învingând anumite comportamente nutriţionale legate de tradiţii. În zona Moldovei tradiţiile, mai ales cele alimentare, sunt considerate importante şi respectate la nivel populaţional. Pornind de la aceste considerente, am încercat să apreciem modul în care se asigură alimentaţia preşcolarilor, în relaţie cu nivelul educaţional matern.

În cadrul lotului examinat, 64,5% din mame aveau studii superioare, 22,6% liceale sau şcoală profesională şi 12,9% postliceale (fig. 1).

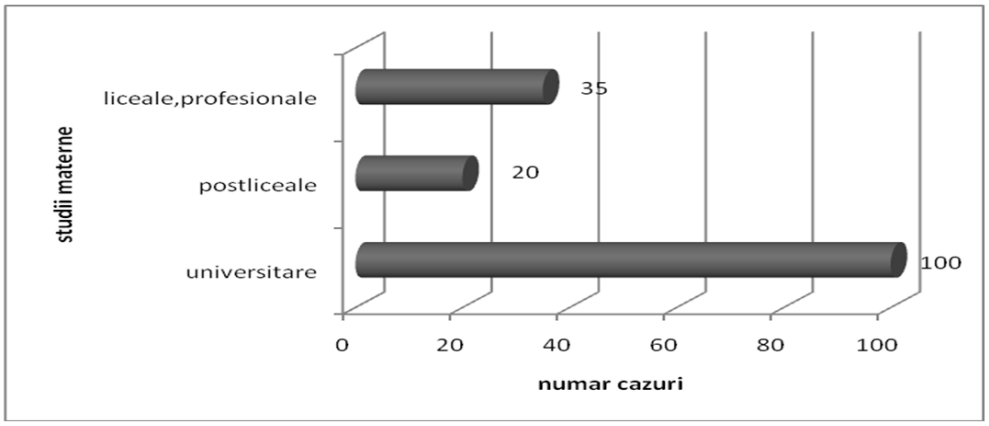

Fig. 1. Repartiţia lotului de mame în relaţie cu nivelul studiilor

În numai 6 (3,9 % cazuri) mamele aveau studii profesionale, ceea ce a impus asocierea acestora cu cele cu pregătire liceală pentru a evita dispersia prea mare a lotului.

2. Frecvenţa consumului săptămânal al unor anumite produse alimentare.

Laptele a fost consumat în majoritatea cazurilor (70, 3%), de 4-7 ori pe săptămână şi doar o dată pe săptămână (7, 1 %).

Diferenţele în ce priveşte ritmul consumului săptămânal de lapte au fost nesemnificative statistic ($p>o,o5$, $\chi^2 = 2,24$), ceea ce se explică prin obiceiuri alimentare asemănătoare, chiar şi în condiţiile în care informaţiile deţinute de mamă erau diferite (tab. I).

TABELUL I

Consumul săptămânal de lapte de către copiii incluşi în studiu în relaţie cu nivelul educaţional al mamelor

Nivelul studiilor materne	Frecvenţa consumului săptămânal de lapte (zile)		
	1	2-3	4-7 *
Studii universitare	9	18	73
Postliceale	2	6	12
Liceale, profesionale	0	11	24
Total Nr.	11	35	109
%	7, 1	22, 6	70, 3

***pentru valorile mai mici de 10 proporţiile sunt orientative**

3. Consumul brânzeturilor s-a dovedit a fi mai ales de 2-3 ori pe săptămână (47,7%), comparativ cu familiile în care aportul de brânzeturi era zilnic (21,9%), sau cele în care acesta era absent (7,7%). Diferenţele s-au dovedit a fi puternic semnificative statistic ($p<0,005$). Insuficienţa sau lipsa acestor produse din alimentaţia preşcolarilor este o eroare gravă perturbând, astfel aportul de proteine de calitate superioară, grăsimi, vitamine şi elemente minerale (fig. 2).

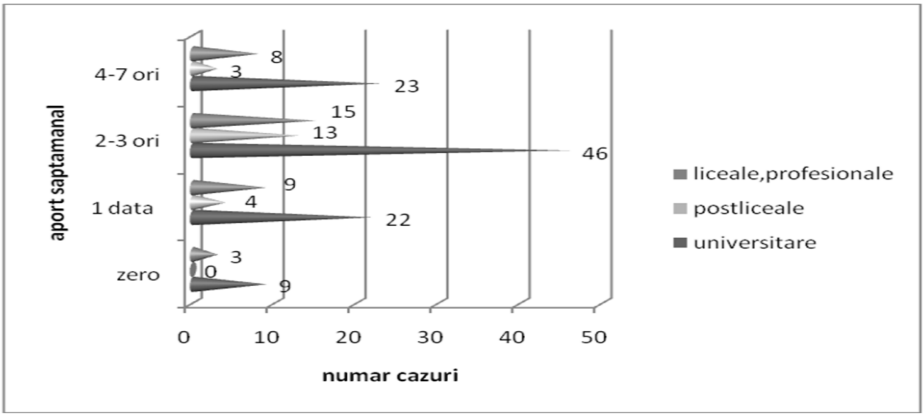

Fig. 2. Consumul săptămânal de brânzeturi în relaţie cu nivelul studiilor materne

Diferenţele nivelului de consum au avut o relaţie nesemnificativă statistic cu studiile materne ($p >0,05$, $\chi^2 = 4,0$), situaţie ce poate fi explicată, cel puţin în parte, prin faptul că obiceurile alimentare ale preşcolarilor sunt asemănătoare, indiferent de pregătirea mamei şi confirmă faptul că tradiţia este mai puternică comparativ cu informaţiile cotidiene actualizate normelor moderne.

Programele naţionale de orientare în domeniul alimentaţiei, vor avea impact favorabil dacă debutează în perioada de preşcolar, şi în cooperare cu familia.

La această categorie de vârstă consumul optim de brânzeturi va fi de 3-4 ori pe săp-

tămână. Studiul nostru a evidenţiat un aport dominant de 2-3 ori pe săptămână (49,0%), dar şi existenţa a 3,9% de situaţii cu un consum absent şi similar 3,9% cu unul excesiv (4-7 ori/săptămână).

Rezultatele cercetărilor au dovedit existenţa unor diferenţe nesemnificative statistic ($p > 0,05$, $\chi^2 = 9,01$).

4. Consumul de carne pasăre este recomandat prioritar pentru preşcolari. În lotul inclus în studiu aportul dominant a fost de numai 2-3 ori pe săptămână (48,4%). 36,8% de 4-7 ori, dar şi 2,6% de consum absent. Deficienţele legate de consumul de carne de pasăre apar la toate grupurile de preşcolari, indiferent de studiile materne, diferenţele constatate fiind nesemnificative statistic ($p>0,05$, $\chi^2 = 1,96$) (tab. II).

TABELUL II

Distribuţia cazurilor în relaţie ce aportul săptămânal de carne de pasăre

Nivelul studiilor materne	Frecvenţa consumului de carne de pasăre/săptămână*			
	Zero	1	2-3	4-7
Studii universitare	2	14	47	37
Postliceale	1	1	10	8
Liceale, profesionale	1	4	18	12
Total nr.	4	19	75	57
%	2,6	12,2	48,4	36,8

*** Pentru valorile mai mici de 10 proporţiile sunt orientative**

5. Produsele de origine vegetală. În alimentaţia preşcolarilor alături de produsele de origine sunt necesare şi cele vegetale, adecvate cantitativ şi calitativ, pentru a evita dezechilibre nutriţionale.

Produsele cerealiere studiate au fost pastele făinoase şi orezul, produse bogate în proteine vegetale, amidon şi oferă un aport caloric crescut. În majoritatea cazurilor (55, 5%) acestea au fost incluse în consum de 2-3 ori pe săptămână, prin contrast cu 5, 2% din cazuri în care consumul a fost absent sau în 12,9%, în exces, de 4-7 ori pe săptămână. Diferenţele pe grupuri de preşcolari şi categoriile de studii materne au fost nesemnificative statistic ($p> 0,05, \chi^2 - 9,35$).

Cartofii sunt legumele cele mai recomandate pentru preşcolari datorită digestibilităţii lor uşoare. În studiul nostru au fost incluşi în meniul săptămânal de 2-3 ori (54, 8%), dar în 3, 9% răspunsurile au fost negative şi 22, 6% consumul de doar o dată pe săptămână. Repartiţia situaţiilor de consum pe grupuri de preşcolari au evidenţiat diferenţe nesemnificative statistic ($p > 0,05$ $\chi^2 = 2,2$), care se pot explica prin faptul că mamele sunt ancorate în tradiţii, astfel că greşelile constatate nu ţin de nivelul lor educaţional.

6. Consumul de fructe a fost asigurat cel mai frecvent de 4-7 ori pe săptămînă (81,9%), iar în 14,2 %, de 2-3 ori şi cu 3,9% de consumuri insuficiente. Programele de suplimentare a aportului de fructe, iniţiat de guvern, au puţine şanse de reuşită deoarece se adresează doar la 3,9% din copii. În restul familiilor consumul este prezent, iar un consum în exces al fructelor ar aduce o cantitate mai mare de vitamine, minerale şi glucide (fig. 3).

În majoritatea cazurilor, în populaţia din zona inclusă în studiu, consumul de fructe era optim şi nu impunea o suplimentare prin program.

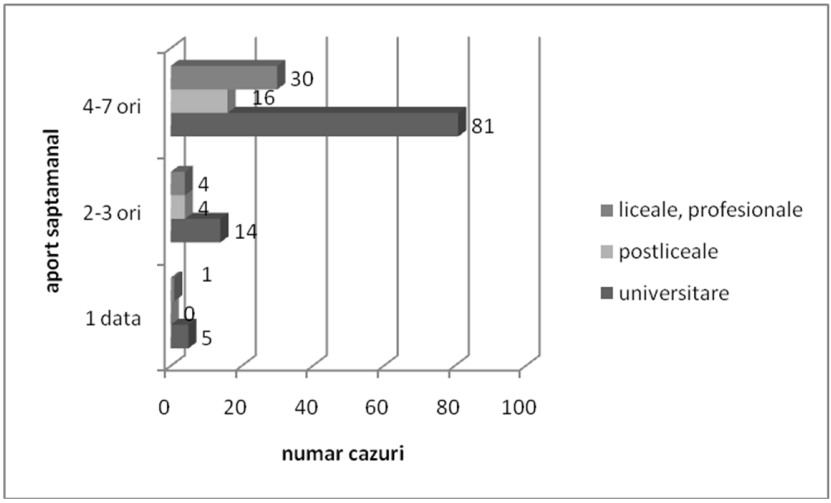

Fig. 3. Frecvența consmului săptămânal de fructe la lotul de preşcolari inclus în studiu, în relație cu nivelul educațional al mamelor

Şi în acest caz pregătirea educațională a mamei nu a avut influență statistică semnificativă ($p>0,05$ $\chi^2 = 2,34$).

7. Consumul de dulciuri considerat "modelul permanent al copilăriei", are caracter tradițional când părinții recurg la dulciuri drept recompensă (8,9). În cazul lotului de copii studiat a fost dominant aportul de 4-7 ori pe săptămână (56,8%), 2-3 ori (30,9%) şi absența acestuia afirmată de 1,2% dintre părinți, situație nefavorabilă deoarece celula nervoasă foloseşte glucidele drept unică sursă de energie (tab. III).

TABELUL III

Frecvența consumului de dulciuri la preşcolarii incluşi în studiu

Nivelul studiilor materne	Frecvența consumului de dulciuri/săptămână			
	Zero	1	2-3	4-7
Studii universitare	2	10	35	53
Postliceale	0	4	4	12
Liceale, profesionale	0	3	9	23
Total nr.	2	17	48	88
%	1,2	10,9	30,9	56,8

Consumul de dulciuri nu a avut relații semnificative statistic ($p>0,05$, $\chi^2 = 5,17$) cu nivelul studiilor materne, deci obiceiurile alimentare ale preşcolarilor, nu au dovedit a avea relație directă cu nivelul educațional al mamei.

CONCLUZII

În studiul realizat au fost dominante mamele cu studii universitate, deci care deținеau multe informații legate de modul de îngrijire şi de alimentația corectă a preşcolarilor.

Consumul de lapte a avut în majoritatea cazurilor un ritm de 4-7 ori pe săptămână; cel de brânzeturi, ouă şi carne de pasăre de 2-3 ori, iar comparația între grupurile de studii materne au marcat diferențe nesemnificative statistic ceea ce explică existența unor obiceiuri alimentare asemănătoare, indiferent de gradul educațional al mamei.

Aportul de paste făinoase şi cartofi a fost practicat îndeosebi de 2-3 ori/săptămână, iar fructele, în majoritatea cazurilor de 4-7 ori.

Se poate considera că realizarea unor programe naționale de orientare nutrițională sanogenă se impun a fi stabilite în raport de cunoaşterea obiceiurilor alimentare ale populației, iar în cazul preşcolarilor studiați nu s-a dovedit a fi necesară suplimentarea cantității de fructe, deoarece acestea sunt incluse în mod adecvate în rația zilnică.

NOUTĂȚI

HAFNIA SPP.- DIAGNOSTIC ŞI TRATAMENT

În acest studiu au fost incluse 68 de tulpini de Hafnia identificate pâna le nivel de specie pe baza secvențierii au fost învestigate în scopul stabilirii caracterelor fenotipice utile şi accesibile în toate laboratoarele. Au fost investigare patru teste; utilizarea malonatului, fermentarea salicilinei şi a arabinozei şi expresia beta glucozidazei care au incadrat corect tulpinile investigate fie ca *H.alvei* sau *H.paralvei*. Testarea sensibilității la antibiotice a fost făcută pentru 35 tupini utilizând E test . Toate tulpinile au fost sensibile la aminoglicozide, chinolone, carbapeneme şi monobactam. Majoritatea tulpinilor au avut CMI pentru colistin mai mare sau egal cu 2 µg/ml. De asemenea, 70% din tulpinile testate produc o toxină citolotică activă pe liniile Vero care ar putea avea un rol în patogenia gastroenteritei. (Abbott S, Moler S, Green N, Tran R et all.Clinical and laboratory Diagnostic characteristics and Cytotoxigenic Potential of Hafnia alvei and Hafnia paralvei Strains. *J Clin Microbiol* 2011:3191-3197).

Ecaterina Enache

ASPECTE CLINICO-EPIDEMIOLOGICE ŞI PARTICULARITĂŢI ALE SENSIBILITĂŢII LA ANTIBIOTICE ÎN INFECŢIA GONOCOCICĂ

Aida Corina Bădescu[1], Elena Duca[2], Daciana Elena Brănişteanu[3], C. Dobre[4], Laura Gheucă Solovăstru[3], Laura Stătescu[3], Gabriela Stoleru[3], A. Vasîlca[4], D. Vâţă[3], Zenaida Petrescu[3]

4. Spitalul Clinic de Urgenţe „Sf. Spiridon" Iaşi, Clinica de Dermatologie

CLINICO-EPIDEMIOLOGICAL FEATURES AND ANTIMICROBIAL RESISTANCE PATTERN IN GONOCOCCAL INFECTION (Abstract): **Aim**: To analyze clinical and epidemiological features in patients with gonococcal infection attended Dermato-Venerology Clinic in Iasi and regional dermato-venerology offices and to evaluate gonococcal antimicrobial resistance pattern. **Methods:** The study was carried out on 129 patients clinically diagnosed and bacteriologically confirmed with gonococcal infection who were subsequently submitted to a questionnaire. We studied their demographic characteristics (sex, age, nationality, marital status), clinical features (site of infection, symptoms, concurrent STI, previous history of gonorrhoea) and behavioral aspects (education, number and type of sexual partners, safe sexual practices). **Results:** We found in our patients a strong association of gonorrhoea with young male individual, poor educational level and with clinical symptoms of urethritis. The level of antimicrobial resistance is higher than in other European countries. **Conclusions:** The poor health-seeking behavior, symptoms not specific enough, resistance pattern, lack of accessible and sensitive diagnostic methods lead to undiagnosed and probably mistreated gonorrhoea. **Key words**: GONOCOCCAL INFECTION, EPIDEMIOLOGY, ANTIMICROBIAL RESISTANCE

Infecţia gonococică reprezintă o problemă majoră de sănătate publică, atât prin incidenţa în creştere la nivel mondial cât şi datorită emergenţei şi răspândirii tulpinilor de gonococ rezistente la antibiotice. Dezvoltarea rezistenţei gonococului la antibioticele utilizate curent compromite atât managementul individual al cazurilor de gonoree cât şi eficienţa programelor de control. Nivelul ridicat al preocupărilor pentru controlul infecţiei gonococice peste tot în lume este justificat şi datoriă implicării gonoreei în cresterea de aproximativ 500 de ori a riscului de transmitere a HIV (1).

Controlul infecţiei gonococice întâmpină, de asemenea, dificultăţi legate de de insuficienţa datelor asupra incidenţei şi prevalenţei cazurilor asimptomatice sau cu simptomatologie necaracteristică, accesibilitate redusă la mijloace şi metode sensibile de diagnostic, reticenţă la raportarea cazurilor confirmate, mai ales în medicina privată (1).

Scopul studiului este de a realiza anali-

za caracteristicilor clinice şi epidemiologice ale infecţiei gonococice la pacienţii asistaţi în Clinica de Dermatologie din Iaşi şi în cabinetelor dermato-venerologice din teritoriu, în perioada septembrie 2004 - decmbrie 2008.

MATERIAL ŞI METODĂ

Lotul de studiu a fost constituit din 129 pacienţi, diagnosticaţi clinic şi confirmaţi bacteriologic cu infecţie gonococică. După recoltarea prelevatelor cu tampoane din dacron acestea au fost introduse imediat în mediul de transport - Amies cu cărbune. Însamânţarea probelor s-a realizat pe agar Thayer Martin selectiv şi neselectiv, cu incubare 24-48 ore la 35°C, în atmosferă umedă, cu 5-10% CO_2. Identificarea izolatele s-a făcut pe baza caracterelor microscopice, de cultură şi biochimice (galerii API NH, Bio Merieux) (2). Pacienţii confirmaţi bacteriologic cu infecţie gonococică au răspuns la un chestionar pentru a analiza particularitaţile demografice (sex, vârstă, nationalitate, stare civilă), clinice (localizare, simptomatologie, antecedente de infecţie gonococică sau alte boli cu transmitere sexuală), educaţionale şi comportamentale (nivel educaţional, număr de parteneri sexuali, caracteristicile sursei de infecţie, utilizarea metodelor de protecţie). Pentru un număr de 113 tulpini s-a făcut testarea sensibilităţii la penicilină 10UI, tetraciclină 30µg, ciprofloxacin 5µg, spectinomicină 100µg, cefixim 5µg, ceftriaxonă 30µg, şi au fostinterpretat rezultatele conform criterilor interpretative ale CLSI, cu tulpina de referinţa *N. gonorrhoeae* ATCC 49226 (3).

REZULTATE

1. *Caracteristici demografice*.

Au fost confirmate bacteriologic 129 cazuri de infecţie gonococică, 116 cazuri (89.92%) la bărbaţi şi 13 cazuri (10.07%) la femei, raportul fiind de 11,2/1.

Vârsta subiecţilor din lotul investigat a fost de 13- 64 ani, cu o medie de 28,3 ani, majoritatea cazurilor (101/78,29%) fiind semnalate la grupurile de vârstă 15-34 ani

Majoritatea pacienţilor au provenit din mediul urban (103/79,85%), cu domiciliul în judetul Iaşi (107/82,94%). Pacienţii investigaţi au fost români (71/86.64%), rhomi (1/1,11%) şi moldoveni (1/1.24%); 52(40,31%) fiind căsătoriţi, 35 (27,13%) sunt căsătoriţi iar 41 (31,78%) trăiesc în concubinaj (tab.I).

2. *Caracteristici clinice*

Toţi pacienţii de sex masculin au prezentat simptome de uretrită acută purulentă, cu debut la o perioda variind între 2 şi 7 zile de la contactul infectant (medie 3,5 zile. La 2 (1,55%) pacienţi secreţia a fost mucopurulentă iar alţi 2 (1,55%) au prezentat simptome de afectare testiculară. Toate pacientele diagnosticate au fost în contact cu bărbaţi suferinzi de uretrită gonococică şi au prezentat clinic inflamaţia mucoasei cervicale şi scurgere vaginală mucopurulentă. Nu s-au izolat tulpini de gonococ cu localizare faringienă sau rectală.

Antecedente de infecţie gonococică au prezentat 15 (11,62%), 20 (15,5%) au fost diagnosticaţi cu sifilis iar 12 (9,3%) au avut vegetaţii veneriene.

În 32 (24,8%) din cazurile investigate a fost evidenţiată practicarea tratamentului înainte de prezentarea la medic (ciprofloxacin, ofloxacin, peniciline, doxiciclina) iar 10 (7,75%) nu au precizat medicaţia administrată.

S-a evidenţiat prezenţa îmbolnăvirilor predominant la elevi şi la cei cu un nivel de şcolarizare redus.

Toţi pacienţii diagnosticaţi cu infecţie gonococică s-au declarat eterosexuali, doar 2 indivizi au semnalat un contact sexual

extragenital; 114 dintre ei (88,37%) au avut mai mult de 5 parteneri sexuali iar 19 (14,72%) au avut mai mult de 4 parteneri în ultimul an.

TABELUL I

Unele caracteristicile epidemiologice ale pacienţilor cu gonoree incluşi în studiu

Caracteristicile pacientului		**Nr.**	**%**
Sex	Masculin	116	89,92
	Feminin	13	10,07
Mediu de proveniență	Urban	103	79,85
	Rural	26	20,15
Vârstă	<15	3	2,32
	15-24	61	47,28
	25-34	40	31,0
	35-44	15	11,62
	45-54	6	4,51
	>55	4	3,1
Nivel de pregătire	gimnaziu	70	54,26
	studii medii	51	39,53
	studii superioare	8	6,2
Status marital	căsătoriți	17	40,47
	necăsătoriți	10	23,8
	concubinaj	14	33,33
	văduvi	1	2,38
Orientare sexuală	heterosexuali	127	97,61
	homosexuali	2	2,38
Număr de parteneri sexuali	1	1	2,38

	>5	13	30,95
	>10	23	54,76
Antecedente de ITS	Da	13	30,95
	Nu	29	69,04

3. *Caracteristici educaţionale şi comportamentale*

Nici unul dintre cei intervievaţi nu utilizează, în mod constant, prezervativul şi doar 10(7,75%) îl folosesc ocazional.

Sursa de infecţie a fost cunoscută la toate femeile din lotul de studiu iar la bărbaţi în 44 cazuri (34,1%); 39 (30,23%) au afirmat că nu cunosc identitatea sursei iar 28 (21,7%) au declarat că au contactat infecţia de la o prostituată. 2 dintre bărbaţi (1,55%) s-au infectat in străinătate.

4. *Sensibilitatea la antibiotice*

Dintre tulpinile de gonococ izolate de la pacienţii luaţi în studiu pentru113 tulpini s-a testat sensibilitatea la antibiotice.

TABELUL II

Nivelul rezistenţei la antibiotice a tulpinilor de gonococ

P=penicilină; TE=tetraciclină; CIP=ciprofloxacin; CFM=cefixim; CRO=ceftriaxonă; SPT= spectinomicină; S= sensibil; R= rezistent.

În toţi cei 5 ani luaţi în studiu s-a remarcat un nivel foarte ridicat al rezistenţei la penicilină (84,21-100%) şi la tetraciclina (82,6-85,71) iar rezistenţa la ciprofloxacin a depăşit nivelurile semnificative clinic; la cefixim avem două tulpini cu sensibilitate redusă; nu s-au izolat tulpini rezistente la ceftriaxonă sau spectinomicină (tab.II).

DISCUŢII

Numărul de cazuri de gonoree raportate este în scădere la nivel mondial deşi incidenţa altor infecţii cu transmitere sexuală este în creştere (1). În zona Moldovei se înregistrează aceeaşi scădere a numărului de cazuri raportate de gonoree (4,5), motiv pentru care studiul sensibilitatăţii la antibiotice este realizat pe tulpini izolate până in 2008, pentru a avea relevanţă statistică. Lotul nostru de pacienti a fost format în majoritate din bărbaţi, simptomatologia acută caracteristică determinând prezentarea

acestora la medicul de familie sau dermatovenerolog. Femeile cu infecţie gonococică, frecvent asimptomatice sau cu simptomatologie nespecifică, fie nu se adresează medicului, fie se adresează medicului de familie sau ginecolog. În condiţiile în care metode sensibile şi specifice de depistare şi de identificare a *N. gonorrhoeae* nu sunt disponibile de, rutină aceste cazuri nu sunt diagnosticate corect şi cu mare probabilitate nu sunt tratate eficient. Toate cazurile de cervico-vaginita diagnosticate de noi au fost contacte ale unor pacienţi cu uretrita gonococică.

În lotul investigat s-a demonstrat o incidenţă semnificativă a infecţiei la grupurile de vârstă 15-35 ani, majoritatea cazurilor fiind din mediu urban, celibatari şi de etnie română. Nivelul educaţional al pacienţilor este scăzut, lucru susţinut atât de nivelul redus de şcolarizare cât şi de datele legate de cunoaşterea şi utilizarea metodelor de protecţie, numărul mare de parteneri sexuali, frecvent necunoscuţi, sau de incapacitatea indivizilor de a preciza medicaţia administrată. Grupul de vârstă 15-19 ani, cu incidenţă mare a infecţiei şi cu comportament cu risc ca urmare a vârstei mici de debut a vieţii sexuale, numărul mare de parteneri sexuali şi necunoaşterea metodelor de protecţie, impune includerea prioritară în programelor educaţionale de prevenţie a BTS.

Toţi pacienţii incluşi în studiu s-au declarat eterosexuali, deşi datele din literatură subliniază incidenţa crescută la bărbaţii homosexuali (6), motiv pentru care nu am izolat tulpini faringiene sau rectale de gonococ.

La insuficienţa reţelei de laboratoare care să poată depista şi identifica *N. gonorrhoeae*, se adaugă lipsa de adresabilitate a personalului medical. Examenul microscopic, utilizat de rutina pentru identificarea etiologiei gonococice, este insuficient de sensibil şi de specific, mai ales în infecţii cronice, pluritratate sau pentru diagnosticul infecţiei gonococice la femei. Metodele de diagnostic molecular (foarte sensibile, ce permit diagnosticul comcomitent a mai multor BTS) sunt inaccesibile în acest moment în România (1,2) .

Eficienţa redusă a programelor de control este dependentă şi de accesul larg la antibiotice al pacienţilor, ce favorizează automedicaţia şi indicatiile terapeutice ale personalului medical fără expetiză în terapia acestei infecţii. Astfel s-a ajuns la apariţia tulpinilor multiplu rezistente la antibioticele utilizate curent în terapia sindromică.

Cercetările efectuate pe lotul de pacienţi luaţi în studiu a evidenţiat un nivel foarte ridicat al rezistenţei la penicilină, tetraciclină şi ciprofloxacin, concordant cu datele raportate intr-un alt studiu realizat în judeţul Suceava (5), dar nu s-a constatat rezistenţă la ceftriaxonă şi spectinomicină. În două cazuri s-a semnalat o scădere a sensibilităţii la cefixime. În zona Moldova antibioticul de elecţie pentru tratamentul infecţiilor gonococice ramâne ceftriaxona. Nivelurile de rezistenţă au fost mai mari decât cele raportate în alte tări europene (7,8) dar comparabile cu cele din tările asiatice (6).

Raportarea cazurilor de gonoree întâmpină dificultăţi, boala fiind privită cu reticenţă de către pacient, mai ales în serviciile medicale private. Rapoartele sistemelor de supraveghere europene semnalează subraportarea din ţările Europei de Est (7), motiv pentru care alocarea fondurilor pentru pro-

gramul național de prevenție şi combatere a BTS este suboptimal

CONCLUZII

Slaba adresabilitate la medic şi inaccesibilitatea unor metode sensibile şi specifice de diagnostic duc la o subdiagnosticare a infecției gonococice şi, în consecință, la aplicarea unui tratament incorect. Controlul infecției gonococice în Moldova implică tratamentul corect al cazurilor diagnosticate, cu antibiotice active asupra tulpinilor circulante, depistarea activă a cazurilor, mai ales la femei cu infecții asimptomatice, supravegherea sensibilității la antibiotice a tulpinilor circulante dar şi instituirea unor programe eficiente de prevenție, educaționale pentru înlăturarea unor comportamente prezente în special la grupurile populaționale cu risc crescut.

EXPERIMENTAL RESEARCHES ON THE EFFECTS OF A *CETRARIA ISLANDICA* EXTRACT ON OXIDATIVE STRESS IN LABORATORY ANIMALS (Abstract): **Aim:** Experimental researches on the effects of a *Cetraria islandica* extract, with or without magnesium association, on oxidative stress in rats. **Material and methods:** The experiments were carried out on Wistar rats, treated intraperitoneally for 14 days at single daily dose as follows: Group 1**:** Saline solution (SS) (0.5 ml/100g bw/day); Group 2**:** Subcutaneous pellets, SS; Group 3: Levamisole (LEV) (10mg/kbw/day); Group 4: Subcutaneous pellets, LEV; Group 5: Prednison (PDN) (5mg/kbw/day); Group 6: Subcutaneous pellets, PDN; Group 7: $MgSO_4$ (5mg/kbw/day); Group 8: Subcutaneous pellets, $MgSO_4$; Group 9: *C. islandica* (Ci) extract (21.56mg/kbw/day); Group 10: Subcutaneous pellets, Ci; Group 11: Ci+$MgSO_4$; Group 12: Subcutaneous pellets, Ci+$MgSO_4$. At the end of the experiment blood samples were collected for assessing the following oxidative stress parameters: malonaldehyde, catalase, glutathione peroxidase, glutathione levels. **Results**: In the rats with or without experimentally-induced granuloma, repeated administration of Ci for 14 days resulted in a decrease of malonaldehyde, catalase, glutathione peroxidase activity, and an increase in glutathione levels. The association of magnesium augmented the antioxidant effect of Ci in this experimental model. **Conclusions**: In our study experimental conditions *C. islandica* extract determined adaptogenic-antistress effects, confirmed by its actions on oxidative stress parameters. **Key words**: *CETRARIA ISLANDICA,* IMMUNOMODULATION, OXIDATIVE STRESS.

Există o varietate largă de imunomodulatori de origine vegetală cu importante efecte antioxidante şi/sau adaptogene (1,2). În grupul adaptogenilor se încadrează şi principiile active din *Cetraria islandica.* Studiile din literatura de specialitate au evidenţiat că principiile active conţinute în *C. islandica* prezintă acţiune antimicobacteriană, antifungică, antivirală, antitumorală şi imunomodulatoare (3,4,5).

Unele studii clinice au arătat că magneziul nu este implicat direct în menţinerea balanţei oxidanţi/antioxidanţi la pacienţii supuşi unui stres cronic, dar suplimentarea cu magneziu la aceşti pacienţi a fost urmată de creşterea depozitelor de magneziu, creşterea nivelului seric al vitaminei E şi, consecutiv, ameliorarea proceselor de pe-

roxidare lipidică (6).

Scopul studiului a constat în cercetarea experimentală a efectelor de tip antioxidant ale extractului din *C. islandica* în monoterapie sau în asociere cu Mg.

MATERIAL ŞI METODĂ

Pentru experiment au fost utilizate 12 loturi de câte 6 şobolani Wistar, cu greutate cuprinsă între 180-200g, cu repartiţie uniformă pe sexe, proveniţi de la Institutul de Sănătate Publică din Iaşi, trataţi conform schemei: **L1** = SF= Ser fiziologic (0,5ml/100g c/zi); **L2** = SFp = Pelete subcutanate, ser fiziologic (0,5ml/100g c/zi); **L3** = LEV = Levamisol (10mg/kg c/zi); **L4** = LEVp = Pelete subcutanate, Levamisol (10mg/kg c/zi); **L5** = PDN = Prednison (5mg/kg c/zi); **L6** = PDNp = Pelete subcutanate, prednison (5mg/100g c/zi); **L7** = $MgSO_4$ = $MgSO_4$ (5mg/kg c/zi); **L8** = $MgSO_4$p = Pelete subcutanate, $MgSO_4$ (5mg/kg c/zi); **L9** = Ci = Extract din *C. islandica* (21,56mg/kg c/zi); **L10** = Cip = Pelete subcutanate, Ci (21,56mg/kg c/zi); **L11** = Ci + $MgSO_4$= Ci (21,56mg/kg c/zi) + $MgSO_4$ (5mg/kg c/zi); **L12** = Ci + $MgSO_4$p = Pelete subcutanate, Ci (21,56mg/kg c/zi) + $MgSO_4$ (5mg/kg c/zi).

Substanţele au fost administrate în doză unică zilnică, la ora 8 dimineaţa, timp de 14 zile, pe cale intraperitoneală. Testarea Ci s-a realizat comparativ cu LEV, imunomodulator de sinteză, cu frecvente implicaţii practice, şi respectiv, PDN, un analog glucocorticosteroidian, derivat cu puternice efecte antiinflamatoare şi imunosupresoare. Efectele Ci au fost analizate în monoterapie şi în asociere cu Mg, sub forma $MgSO_4$.

În a opta zi a experimentului, la animalele din loturile notate cu „p", s-a practicat testul granulomului, apoi s-a continuat administrarea substanţelor conform schemei de mai sus. Doza din Ci reprezintă 1/80 din DL_{50}. După 14 zile de tratament s-a recoltat sânge din plexul retroorbitar şi au fost determinaţi următorii parametri ai stresului oxidativ: activitatea malondialdehidei (MAD), catalazei, glutation peroxidazei şi a glutationului redus. Activitatea enzimelor a fost determinată printr-o reacţie de culoare citită la un spectrofotometru tip UV-VIS (HP 8453). Rezultatele au fost apoi prelucrate statistic folosind testul „t-Student". Valoarea $p<0,05$ a fost considerată semnificativă statistic.

Cercetările au fost realizate în conformitate cu recomandările Comisiei de Etică a Universităţii de Medicină şi Farmacie „Gr.T. Popa" din Iaşi, în strictă concordanţă cu reglementările etice internaţionale, privind lucrul pe animale de laborator (7).

REZULTATE ŞI DISCUŢII

La loturile martor cu granulom indus experimental şi tratate cu SF s-a constatat o creştere semnificativă statistic a nivelurilor MAD (fig. 1) comparativ cu valorile acestei enzime la animalele tratate cu SF, fără granulom, acest aspect certificând existenţa unor procese peroxidative intense la animalele cu granulom.

Peroxidarea lipidică este dăunătoare reacţiilor ulterioare de neutralizare a radicalilor liberi produşi. Aldehida malonică produsă prin peroxidarea lipidelor pare să fie atât factorul determinant al polimerizării prin legătură încrucişată, cât şi promotorul cromoforului fluorescent, fenomene ce determină alterări structurale proteice şi chiar ale materialului genetic (ADN) (8,9).

LEV a demonstrat efecte antioxidante prin reducerea semnificativă statistic a valorilor serice ale MDA comparativ cu lotul SFp. La animalele din lotul LEVp valorile serice ale MDA au fost semnifica-

tiv statistic mai crescute comparativ cu nivelul de la animalele tratate cu LEV fără granulom, dar semnificativ statistic mai reduse comparativ cu cele de la lotul SFp. PDN a determinat scăderea semnificativă statistic a valorilor serice ale MDA indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom şi comparativ cu cel indus de LEV.

Ci a determinat scăderea semnificativă statistic a valorilor serice ale MDA indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom.

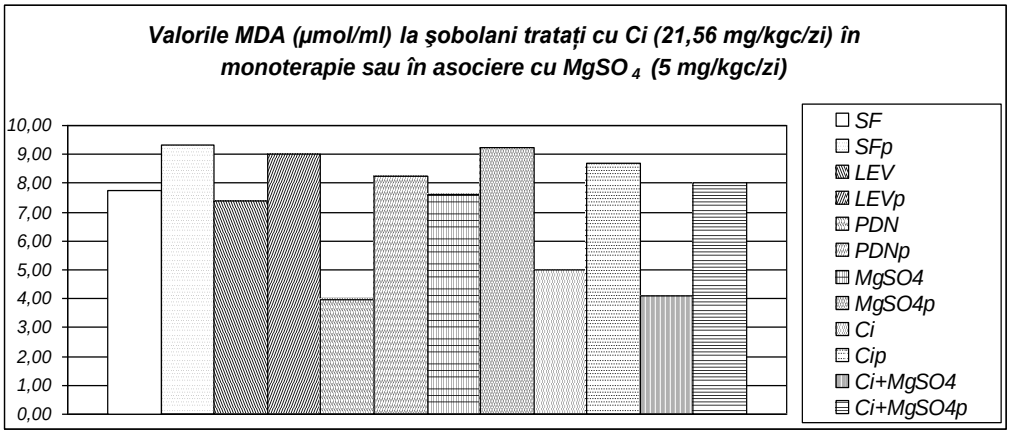

Fig. 1. Activitatea MDA la 14 zile de la debutul studiului

Magneziul nu a influenţat semnificativ statistic nivelurile serice ale MDA, dar a potenţat efectul antioxidant al extractului din *C. islandica*.

S-a constatat că Ci a determinat scăderea peroxidării lipidice semnificativ statistic mai puternică comparativ cu cea indusă de LEV, dar semnificativ statistic mai redusă comparativ cu cea indusă de PDN.

La loturile SFp nivelurile crescute de catalază (fig. 2) au demonstrat falimentul mecanismelor endogene de luptă antioxidantă.

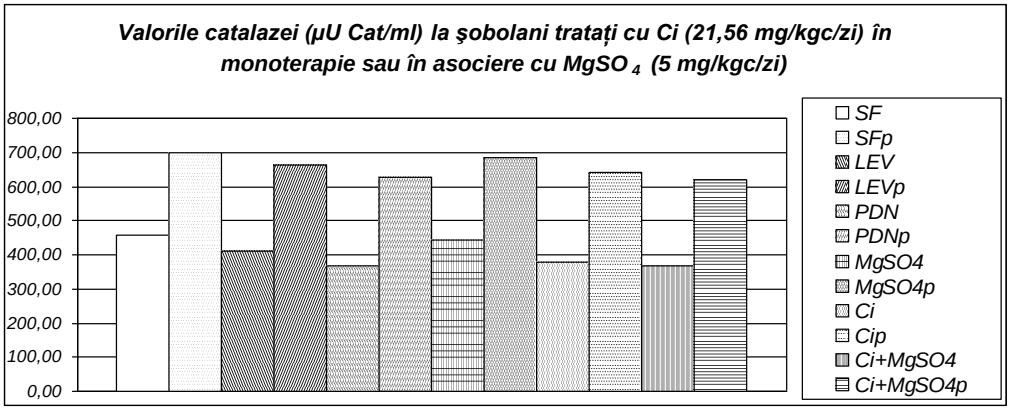

Fig. 2. Activitatea catalazei la 14 zile de la debutul studiului

LEV a determinat scăderea semnificativă statistic a valorilor catalazei comparativ cu lotul SFp. La animalele din lotul LEVp valorile catalazei au fost semnificativ statistic mai crescute comparativ cu nivelul de la animalele din lotul LEV, dar semnificativ statistic mai reduse comparativ cu cele de la lotul SFp. PDN a determinat scăderea semnificativă statistic a valorilor catalazei indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom şi comparativ cu cel indus de LEV.

Ci a determinat scăderea semnificativă statistic a valorilor catalazei indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom. Mg nu a influenţat semnificativ statistic nivelurile catalazei, dar a potenţat efectul antioxidant al Ci.

La lotul SFp nivelurile crescute de glutation peroxidază (fig. 3) a demonstrat condiţii experimentale de stres oxidativ.

LEV a determinat scăderea semnificativă statistic a valorilor glutation peroxidazei comparativ cu SFp. La animalele din lotul LEVp valorile glutation peroxidazei au fost semnificativ statistic mai crescute comparativ cu nivelul de la animalele din lotul LEV, dar semnificativ statistic mai reduse comparativ cu cele de la SFp. PDN a determinat scăderea semnificativă statistic a valorilor glutation peroxidazei, indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom şi comparativ cu cel indus de LEV.

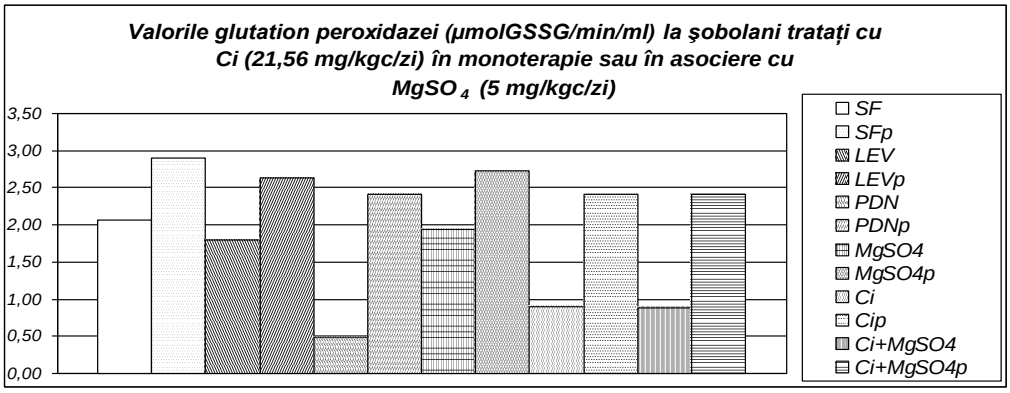

Fig. 3. Activitatea glutation peroxidazei la 14 zile de la debutul studiului

Ci a determinat scăderea semnificativă statistic a valorilor glutation peroxidazei, indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom. Mg nu a influenţat nivelurile glutation peroxidazei, atât în monoterapie, cât şi în cazul asocierii cu extractul din *C. islandica*.

S-a constatat că efectele Ci la animalele cu granulom indus au fost similare cu cele determinate de PDN în aceleaşi condiţii experimentale.

La lotul SFp nivelurile scăzute de glutation redus (fig. 4) au demonstrat consumul său ca substrat al glutation peroxidazei.

LEV a determinat creşterea semnificativă statistic a valorilor glutationului redus comparativ cu lotul SFp. La animalele cu granulom indus experimental şi tratate cu LEV valorile glutationului redus au fost

semnificativ statistic mai scăzute comparativ cu nivelul de la animalele tratate cu LEV fără granulom, dar semnificativ statistic mai crescute comparativ cu cele de la lotul SFp. PDN a determinat creşterea semnificativă statistic a valorilor glutationului redus, indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom şi comparativ cu cel indus de LEV.

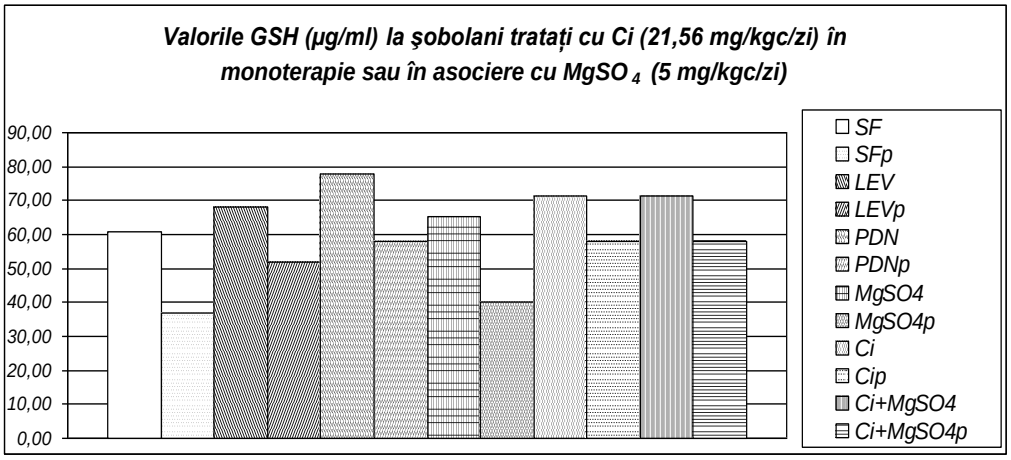

Fig. 4. Valorile glutationului redus la 14 zile de la debutul studiului

Ci a determinat creşterea semnificativă statistic a valorilor glutationului redus indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom. Magneziul nu a influenţat nivelurile glutationului redus, atât în monoterapie, cât şi în cazul asocierii cu extractul din *C. islandica.*

Datele obţinute au demonstrat că extractul vegetal din *C. islandica* a determinat efecte antistres-adaptogene evidenţiate de acţiunea sa asupra enzimelor ce caracterizează balanţa oxidanţi/antioxidanţi (10).

CONCLUZII

Studiile experimentale imunofarmacologice, privind extractul obţinut din produsul vegetal *C. islandica* (codificat Ci), în doză reprezentând 1/80 din DL_{50} (21,56 mg/kgc/zi), administrat în monoterapie sau în asociere cu Mg, sub formă de $MgSO_4$, au condus la următoarele concluzii:

Ci a determinat scăderea semnificativă statistic a valorilor serice ale MDA, catalazei şi glutation peroxidazei, indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom. Magneziul nu a influenţat semnificativ statistic nivelurile serice ale MDA, catalazei şi glutation peroxidazei, dar a potenţat efectul antioxidant al extractului din *C. islandica*. Efectele extractului din *C. islandica* la animalele cu granulom indus au fost similare cu cele determinate de PDN în aceleaşi condiţii experimentale.

Extractul din *C. islandica* a determinat creşterea semnificativă statistic a valorilor glutationului redus, indiferent de condiţiile experimentale, efectul fiind mai puternic la animalele fără granulom. Magneziul nu a influenţat nivelurile glutationului redus, atât în monoterapie, cât şi în cazul asocierii cu extractul din *C. islandica*.

NOUTĂȚI

VALOAREA PREDICTIVĂ A INDICILLOR ANTROPOMETRICI PENTRU MORTALITATEA ŞI MORBIDITATEA PACIENŢILOR DIALIZAŢI

Evaluarea *status*-ului nutriţional al pacienţilor dializaţi este importantă deoarece malnutriţia protein calorică este un factor care influenţează morbiditatea şi mortalitatea acestora. Scopul acestui studiu a fost să argumenteze valoarea predictivă a parametrilor antrpopometrici şi modalitatea în care aceste două caracteristici se corelează. Studiul a inclus 242 pacienţi. Măsurătorile antropometrice au fost făcute în timpul iernii şi s-au referit la date privind pliul cutanat, circumferinţa braţului, înălţime şi greutate. Procentul de grăsime corporală a fost calculat în funcţie de pliul cutanat prezent în regiunea tricepsului, bicepsului, suprascapulară şi suprailiacă. Indicele de masă corporală (BMI) rata catabolizării proteinelor şi factorii de risc cardio-vasculari au fost de asemenea valori luate în discuţie. În urma analizei datelor au fost găsite corelaţii semnificative între parametrii antropometrici (analiza statistică folosită fiind regresia Cox extinsă). De asemenea, fiecare parametru investigat s-a corelat independent cu mortalitatea şi morbiditatea pacienţilor investigaţi. Parametrul cu valoarea predictivă cea mai mare a fost circumferinţa braţului, indicele de masă corporală fiind considerat doar un factor de risc. (Stosovic M, Stanojevic M, Ogrizovic S, Jovanovic, The predictive value of anthropometric parameters on mortality in haemodialysis patients. *NephrolDial Transplant.* 2011; 26: 1367-1374).

PREVENIREA TRANSMITERII INFECȚIEI ÎN LABORATOARELE DE TEHNICĂ DENTARĂ DIN IAŞI

Lucia Bârlean, I. Dănilă, Iulia Săveanu
Universitatea de Medicină şi Farmacie „Gr.T.Popa" Iaşi
Facultatea de Medicină Dentară
Disciplina de Prevenție Oro-Dentară

PREVENTION OF INFECTION TRANSMISSION IN DENTAL LABORATORIES (Abstract). The professional activity in a dental laboratory is associated with a high risk for infection transmission through the manipulation of impressions and prostheses contaminated with patients' saliva and blood. **Aim:** To assess the compliance of dental technicians in Iasi town dental laboratories with the methods used for preventing infection transmission in their practices. **Material and methods:** This questionnaire-based survey included 61 dental technicians aged 22 to 58 years from 29 dental laboratories. The 17 questions were related to the protection equipment, air ventilation, and disinfection of surfaces, instruments, impressions, and prostheses. SPSS 14 system, Chi-Square test were used for data analysis, and the levels of statistical significance were set at $p<0.05$. **Results:** 90.2% of the subjects claim the need of prosthetic items disinfection upon arrival at the laboratory from the dental office ($p<0.05$). The protection equipment is used by 49.1% of the dental technicians included in this survey (full equipment 18.0%, safety glasses 45.9%, mask 37.7%, rubber gloves 19.6%). 59.1% of the laboratories are provided with air ventilation, while surface disinfection is common practice in 85.2%. Of the study subjects 62.1% disinfect the impressions, 26.1% the final prosthesis, and 25.0% disinfect the interocclusal registrations ($p<0.05$). **Conclusions:** Educational programs aimed at increasing dental technicians' awareness of infection control by adopting the most effective prevention measures are essential for reducing the incidence of technicians, dentists, and patients; exposure. **Key words:** PREVENTION, INFECTION CONTROL, EXPOSURE, DENTAL LABORATORY

Controlul infecției reprezintă un domeniu esențial al medicinei dentare, care este asociată unui risc crescut de transmitere a infecției prin contact direct cu fluidele contaminate, indirect prin intermediul unor obiecte contaminate sau prin transmitere încrucişată („cross infection") (1). Potențialul de transmitere a infecțiilor în laboratorul de tehnică dentară este datorat manipulării şi transportului între cabinetul dentar şi laborator a amprentelor, a fazelor intermediare de tratament protetic şi a protezelor contaminate cu bacterii, virusuri sau fungi provenind din saliva şi sângele pacientului (2).

Laboratoarele de tehnică dentară pot dispune de o zonă de recepție pentru evaluarea şi decontaminarea pieselor protetice provenind din cabinetele dentare sau pot funcționa ca o zonă izolată care impune dezinfecția amprentelor, fazelor intermediare şi a protezelor în cabinetul dentar, înainte de intrare în laborator. Ambele

metode sunt eficiente alegerea efectuându-se în funcție de locație, calificarea personalului şi sistemul de organizare (3,4).

Comunicarea eficientă şi coordonarea dintre cabinet şi laborator trebuie să asigure aplicarea procedurilor de curățare, dezinfecție şi sterilizare în vederea eliminării riscului de expunere ocupațională a personalului medical dar şi a pacientului, evitând totodată deteriorarea materialelor protetice prin supraexpunere la acțiunea dezinfectantelor şi dublarea inutilă a protocoalelor specifice de control al infecției (5).

Aplicarea Precauțiilor Universale este esențială în laboratorul de tehnică dentară, ca şi în cabinetul dentar, impunând utilizarea echipamentului de protecție format din halat, mască facială, mănuşi şi ochelari şi aplicarea protocoalelor specifice de igienizare a mâinilor, dezinfecție a dispozitivelor, echipamentelor şi suprafețelor şi sterilizare a instrumentelor reutilizabile (6).

MATERIAL ŞI METODĂ

În scopul evaluării cunoştințelor şi atitudinilor tehnicienilor dentari față de procedurile de control al infecției am instituit un studiu pe bază de chestionar la care au participat 61 de tehnicieni din 29 de laboratoare de tehnică dentară din Iaşi. Lotul a fost format din 31 de bărbați şi 30 de femei cu vârsta cuprinsă între 22 şi 56 de ani. Chestionarul a cuprins 17 întrebări referitoare la necesitatea dezinfecției pieselor protetice în cursul transferului dintre cabinetul dentar şi laboratorul de tehnică dentară, utilitatea măsurilor de prevenire a transmiterii infecției, utilizarea echipamentului de protecție, dezinfecția suprafețelor din laboratorul de tehnică dentară şi soluțiile dezinfectante utilizate. Rezultatele au fost prelucrate utilizând sistemul SPSS 14, testul Chi-Square ($p<0,05$).

REZULTATE

Prelucrarea datelor chestionarului a demonstrat că majoritatea subiecților (93,4%) declară că sunt preocupați şi au cunoştințe privind controlul infecție. 90,2% consideră necesară decontaminarea pieselor protetice provenind din cabinetul dentar la intrarea în laboratorul de tehnică dentară, fără diferențe semnificative în funcție de sex (86,6% dintre femei, 93,5% dintre bărbați). ($p<0,05$) Deasemenea 81,9% dintre tehnicieni (80,0% dintre femei şi 83,8% dintre bărbați) apreciază ca necesară decontaminarea probelor şi a lucrărilor protetice care urmează a fi transportate din laborator către cabinetul dentar (fig.1).

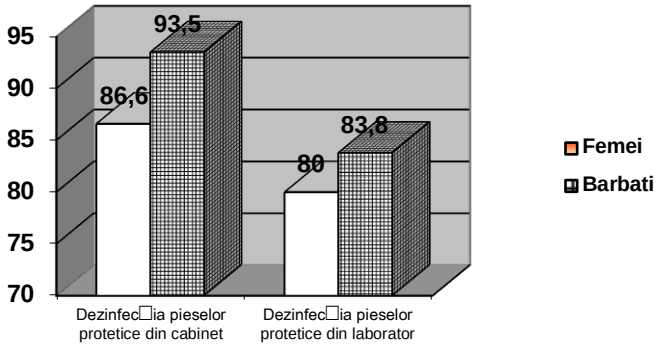

Fig. 1. Distribuția procentuală a tehnicienilor care consideră necesară dezinfecția pieselor protetice în laboratorul şi cabinetul dentar

Măsurile de dezinfecţie şi sterilizare sunt considerate importante pentru tehnicianul dentar de către 86,9% dintre subiecţi. (83,3% dintre femei şi 93,3% dintre bărbaţi). Utilitatea acestor protocoale pentru medic şi pacient este apreciată de 36,4% şi, respectiv,15,5% dintre tehnicieni (fig. 2).

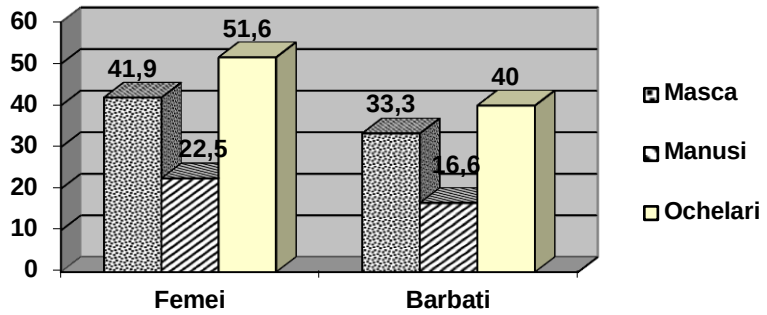

Fig. 2. Distribuţia procentuală a tehnicienilor care consideră utile măsurile de dezinfecţie aplicate în laboratorul de tehnică dentară.

Echipamentul de protecţie, componenta esenţială a Precauţilor Universale, este utilizat de către 49,1% dintre tehnicieni. Subiecţii de sex feminin apelează la echipamentul de protecţie în proporţie mai ridicată (59,0% dintre femei) comparativ cu cei de sex masculin (44,2% dintre bărbaţi) (fig.3).

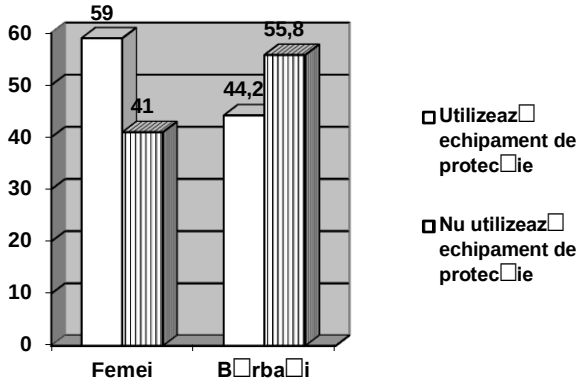

Fig. 3. Distribuţia procentuală a utilizării echipamentului de protecţie în funcţie de sex

Ochelarii de protecţie sunt utilizaţi de către 45,9% dintre tehnicieni (51,6% dintre femei şi 40,0% dintre bărbaţi) în comparaţie cu masca - 37,7% (41,9% dintre femei şi 33,3% dintre bărbaţi) şi mănuşile de cauciuc -19,6% (22,5% dintre femei şi 16,6% dintre bărbaţi). 18,0% dintre tehnicieni declară că utilizează echipamentul complet de protecţie (masca, mănuşi şi ochelari) (fig. 4).

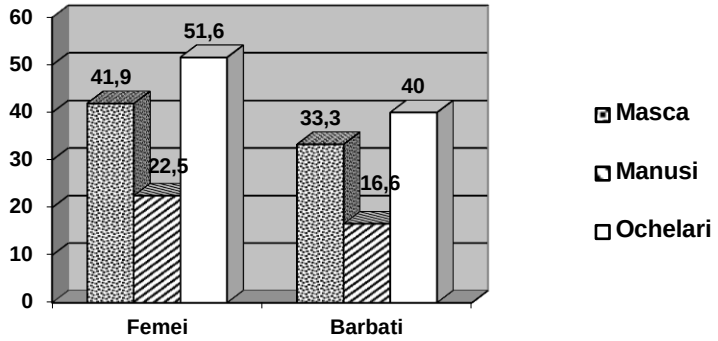

Fig. 4. Utilizarea componentelor echipamentului de protecție în funcție de sex

Evaluarea răspunsurilor referitoare la măsurile de control al contaminării aerului a relevat faptul că 59,1% dintre laboratoare dispun de sisteme de ventilație ($p<0,05$).

Dezinfecția suprafețelor de lucru se practică în 85,2% dintre laboratoarele de tehnică dentară. In majoritatea laboratoarelor dezinfecția suprafețelor se efectuează la începutul şi la sfârşitul zilei de lucru (52,4%) sau numai la începutul zilei (40,9%) ($p<0,05$). In ceea ce priveşte piesele protetice subiecții incluşi în studiu declară că efectuează dezinfecția amprentelor venite din cabinetul dentar (26,1%), a fazelor intermediare de tratament protetic (25.0%) şi a protezelor (26,1%) ($p<0,05$) (fig.5).

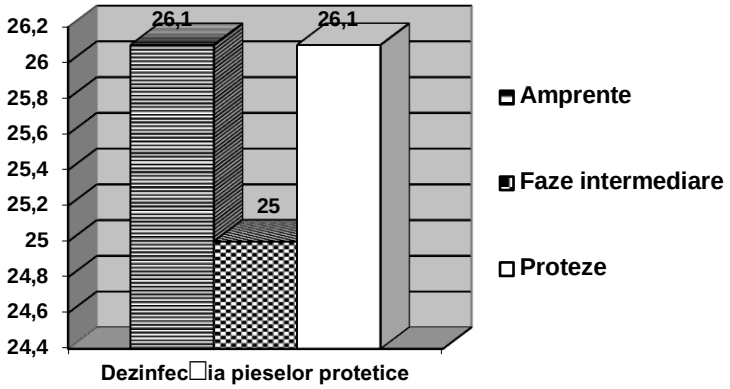

Fig. 5. Dezinfecția pieselor protetice în laboratoarele de tehnică dentară.

Decontaminarea pieselor de mână şi a instrumentarului rotativ se practică de către 36,0% dintre tehnicienii dentari. Majoritatea subiecților utilizează în acest scop proceduri de dezinfecție (31,1%) iar sterilizarea pieselor de mână este menționată de către 4,9% dintre aceştia.

Rata de răspuns la întrebarea privind antisepticele utilizate pentru dezinfecție a fost de 31,2%. Produsele menționate pentru dezinfecția suprafețelor sunt: Perform, alcool alb, Surfanios, Domestos, Zeta 3. Pentru piesele de mână şi instrumentarul rotativ sunt utilizate produse ca: Hexanios, Zeta 1,

Perform iar pentru dezinfecţia pieselor protetice : Hexanios, Zeta 7, Perform, Cloramina, alcool .

DISCUŢII

Personalul medical din laboratoarele de tehnică dentară trebuie să adere la standardele profesionale, legale şi etice în privinţa controlului infecţiei (7,8). Rezultatele studiului relevă faptul că majoritatea tehnicienilor (93,4%) declară că sunt preocupaţi şi posedă cunoştinţe privind mijloacele de prevenire a transmiterii infecţiei în laboratorul dentar. Această atitudine se reflectă în susţinerea necesităţii dezinfecţiei pieselor protetice atât la intrarea cât şi la ieşirea din laborator de către 90,2% şi respectiv 81,9% dintre subiecţi, fără diferenţe semnificative în funcţie de sex. Percepţia subiecţilor participanţi la studiu asupra utilităţii acestor măsuri relevă preocuparea privind protecţia tehnicienilor (86,9%), ignorând importanţa acestora pentru medic şi pacient.

Răspunsurile la întrebările referitoare la echipamentul de protecţie demonstrează că acesta este utilizat doar de jumătate dintre tehnicieni, femeile apelând la aceste bariere fizice de protecţie în proporţie mai ridicată decât bărbaţii. Preocuparea pentru protecţia ochilor este demonstrată de proporţia ridicată a tehnicienilor care utilizează ochelarii de protecţie (45,9%). Această proporţie este mai mare comparativ cu rezultatele raportate de AlDwairi (35,2%)(9) dar mult mai mică decât cea prezentată de Jagger şi colaboratorii (74,2%) (10). Mănuşile de cauciuc sunt folosite de către tehnicieni în proporţie foarte redusă (19,6%) comparativ cu datele raportate de în literatură: AlDwairi şi colaboratorii (24%)(9), Jagger şi colaboratorii (44%) (10) şi Akeredolu şi colaboratorii (60,5%) (11). Aceste rezultate demonstrează ignorarea riscului de expunere la infecţie prin leziuni provocate de obiecte ascuţite în cursul manevrării şi prelucrării pieselor protetice.

Procedurile de control al calităţii aerului în laboratorul de tehnică dentară trebuie să urmărească reducerea riscului de expunere la pulberi, gaze şi agenţi patogeni cu transmitere pe cale aeriană (12). Răspunsurile subiecţilor incluşi în studiu susţin că 59,1% dintre laboratoare dispun de sisteme de ventilaţie ($p<0,05$).

Evaluarea procedurilor de control al transmiterii infecţiei pe cale indirectă prin intermediul suprafeţelor contaminate a relevat faptul că în 85,2% dintre laboratoare se practică dezinfecţia suprafeţelor de lucru. În jumătate dintre laboratoare dezinfecţia suprafeţelor se efectuează la începutul şi la sfârşitul zilei de lucru (52,4%).

Sursa principală de contaminare în laboratorul de tehnică dentară este reprezentată de piesele protetice contaminate cu sângele şi saliva pacienţilor care trebuie să fie dezinfectate, în condiţiile unei comunicări eficiente, în cabinet sau laborator. Rezultatele studiului demonstrează că o proporţie redusă dintre tehnicieni efectuează dezinfecţia amprentelor (26,1%), a fazelor intermediare de tratament protetic (25.0%) şi a protezelor (26,1%) comparativ cu datele prezentate de alţi autori ca Akeredolu şi colaboratorii şi Hatzikyriakos şi colaboratorii care raportează că în 74,4% , respectiv 74,8% dintre laboratoarele dentare amprentele şi piesele protetice sunt dezinfectate la intrarea în laborator (11,13).

Piesele de mână şi instrumentarul rotativ (freze) utilizate în laboratorul dentar sunt dezinfectate doar de o treime dintre subiecţi iar sterilizarea pieselor de mână este menţionată de către 4,9% dintre aceştia. La întrebarea referitoare la antisepticele utilizate pentru dezinfecţie, rata de răspuns

a fost foarte redusă (31,2%), demonstrând lipsa de preocupare şi cunoştințe în acest domeniu .

CONCLUZII

Evaluarea condițiilor de desfășurare a activității în laboratoarele de tehnică dentară privind aplicarea protocoalelor de control al infecției demonstrează necesitatea implementării unor măsuri energice de creştere a nivelului de cunoştințe în acest domeniu. Organizarea acțiunilor de educație medicală şi inițierea de programe specifice trebuie să urmărească creşterea complianței tehnicienilor dentari față de măsurile de control al infecției.

FOOD–DRUG INTERACTIONS: GRAPEFRUIT JUICE (Abstract): Food-drug interactions are increasingly recognized as important clinical events which may change significantly the bioavailability of oral administrated drugs. Grapefruit juice (GFJ) demonstrated multiple interactions with drugs leading to loss of the therapeutic effects or increased side-effects. GFJ decreases pre-systemic metabolism through a) competitive or mechanism-based inhibition of gut wall CYP3A4 isoenzymes and b) P-glycoprotein (P-gp), c) multidrug resistance protein-2 (MRP2) or d) organic anion-transporting polypeptide (OATP) inhibition. Although, GFJ presents high amounts of flavonoids (e.g. naringin, naringenin), furanocoumarins (e.g. 6',7'--dihydroxybergamottin, bergamottin) are the main chemicals involved in the pharmacokinetic interactions. As compounds of GFJ show additive or synergistic effects, all the major furanocoumarins are necessary for the maximal inhibitory effect. Also, related citrus fruits (sweeties, pummelo and sour orange) or various plants containing furanocoumarins may present pharmacological interactions, yet to be discovered. **Key words:** GRAPEFRUIT JUICE, PHARMACOKINETIC INTERACTION, CYP

Food-drug interactions are increasingly recognized as noteworthy clinical events as they may shift the effect of the drug outside of its therapeutic window (leading either to loss of effect or undesired side effects) (1).

The discovery that grapefruit juice (GFJ) can increase the oral availability of some medications was an accidental discovery made in 1989 when GFJ was used to mask the taste of ethanol in a study involving the calcium channel blocker felodipine (2, 3). Subjects consuming GFJ concomitantly with felodipine presented a lower dehydrofelodipine/felodipine area under the curve (AUC) ratio, decreased diastolic blood pressure and an increased heart rate (4).

As population has become more aware of the health benefits of antioxidants found in fruits and vegetables, grapefruit and other fruit juices are frequently consumed worldwide. Especially in the elderly, GFJ is often administrated with medication as it is thought that linking drug administration to a regular event like a meal can improve the patient's adherence to the treatment (5).

GFJ significantly decreases pre-systemic metabolism due to inhibition of: a) gut wall CYP3A4 isoenzymes, b) P-glycoprotein (P-gp), c) multidrug resistance protein-2 (MRP2), d) organic anion-transporting polypeptide (OATP) and e) esterase activity (4-11).

The **most important compounds** of GFJ considered to be involved in the pharmacokinetic interaction are flavonoid glycosides

(narirutin, naringin, naringenin, quercetin, kaempferol, hesperidin, neohesperidin, didymin, and poncirin), furanocoumarins (6',7'-dihydroxybergamottin (DHB), GF-I-1, GF-I-4, bergamottin (GF-I-2), GF-I-5 (bergamottin--6',7'-epoxide), GFI-6, bergapten, epoxybergamottin] and sesquiterpens (nootkatone) (12-15).

Naringin, which gives the pungent taste, is the main flavonoid in GFJ, found in concentrations of 450 mcg/mL (10% of the dry weight of juice) (16). Although naringenin, the metabolite of naringin, demonstrated inhibitory effects on CYP3A4, recent evidence clearly indicate that furanocoumarins are the chemicals responsible for in *vivo* significant GFJ interactions (17, 18).

Among different strains of GFJ, origin, packages and ways of processing, the amount of active ingredients may vary among batches and lots (5).

GF-I-2 and GF-I-4 appear mainly in pulp in comparison to sac, peel or seed of grapefruits. The composition of GF-I-1, GF-I-2 and GF-I-4 in grapefruit pulp are similar to those in juice product, excluding the suspect that furanocoumarins might be the byproducts during juice processing.

Furanocoumarin derivatives have been found in various plants belonging to families like *Rutaceae*, *Apiaceae, Moraceae* and *Fabaceae*. 6',7'-dihydroxybergamottin and bergamottin are the furanocoumarins found in the highest concentration in fresh grapefruit (in the low micromolar range) (16).

The precipitate obtained after the centrifugation of GFJ (which contains GF-I-1, GF-I-2, GF-I-4, GF-I-5 and GF-I-6) presents as strong inhibition of CYP3A4 activity as that of the original juice sample. The supernatant (rich in DHB) presents much weaker CYP3A4 inhibition (17, 18).

a) The cytochrome P450 (**CYP**) enzyme family plays a major role in the metabolism a wide array of xenobiotics including drugs, chemical carcinogens, insecticides and other environmental pollutants (4).

CYP3A4 isoenzyme is found in the intestine and liver and accounts for about 40% to 60% of all CYP450 isoenzymes (19). Intestinal CYP3A4 is found in apical enterocytes and varies 11-fold in protein content among individuals. Intestinal and hepatic CYP3A4 content appear to be regulated independently of each other (5). The susceptibility of CYP3A4 to modulation by food constituents may be related to its high level of expression in the intestine, as well as its broad substrate specificity (13).

Inhibition of the CYP system occurs mainly through two **mechanisms**.

The first and most common mechanism is known as competitive inhibition and results from the competition between the inhibitor and substrate for the same CYP isoenzyme required for substrate metabolism and elimination. The effects of competitive inhibition can be observed after administration of the first dose of the inhibitor.

The second mechanism is known as mechanism-based inhibition. This effect is thought to be caused by furanocoumarins that was initially metabolized by CYP3A4 to a reactive intermediate and then bonded covalently to the enzyme, a process termed "suicide" or "mechanism-based" inhibition.

The structurally modified and inactivated CYP3A4 undergoes rapid proteolysis within the cell and consequently, the return of CYP3A4 activity would require *de novo* enzyme synthesis. The fact that reduced intestinal CYP3A4 protein by GFJ is not associated with increased CYP3A4 mRNA, indicates that there is not an effective feedback mechanism within the enterocyte to up-regulate CYP3A4 synthesis (5, 16). Furanocoumarins inactivate CYP3A4 by the binding of the furanoepoxide to the apoprotein, presumably at or near their respective substrate domains (4). Separating the administration of GFJ and substrate drug by a few hours does not minimize grapefruit-drug interactions (20).

The onset of the interaction can occur within 30 minutes. Complete recovery of the CYP3A4 may take 48 to 72 hours after the last exposure to GFJ. The half-life of disappearance of inhibitory effect of GFJ on CYP3A4-mediated drug metabolism was estimated at 12 hours.

In the case of nisoldipine, increased drug AUC is observed up to 72 h after a 7-day pretreatment period of GFJ (200 ml) three times daily ; repeated administration of juice might be expected to cause a cumulative increase in magnitude of pharmacokinetic interaction (5). GFJ does not affect the pharmacokinetics of these drugs when they are administered intravenously (13).

In a study conducted with human intestinal microsomes by Paine and coworkers, DHB induced a substrate-independent reversible (within 30 minutes) and mechanism--based inhibition on CYP3A4 (21). In contrast, BG (bergamottin), being more lipophilic, was a substrate dependent reversible inhibitor and a substrate-independent mechanism based inhibitor (three hours) (4).

GF-I-1, GF-I-2 and GF-I-4 are not detected in juice samples of apple, grape, orange and tangerine, only trace amounts of GF-I-2 and GF-I-4 appeared in lemon juice, suggesting that furanocoumarins are fairly selective in GFJ.

Depending on KI values (the inhibitor concentration required for half-maximal rate of inactivation) on nifedipine oxidation in human liver microsomes, recent data indicated that dimers and trimers induce a stronger inhibition of CYP3A4 activities than monomers. The inhibitory potencies of furanocoumarins are similar to those shown by a typical inhibitor, metyrapone or strong CYP3A4 inhibitor, ketoconazole (for dimer and trimer structures). Between the two monomers, DHB is more potent than GF-I-2 for CYP3A4 inactivation. A plain core structure, tricyclic ring containing a furan moiety in linear position, is more important than the side chains for furanocoumarins in CYP3A4 inhibition.

In contrast to the results from the extract of GFJ which show similar inhibitory properties on CYP3A4, CYPlA2, CYP2C9, and CYP2D6, isolated GF-I-2 presents clear inhibition of CYP2A6, CYP2C9, CYP2D6, CYP2E1, and CYP3A4, with stronger potencies on CYP2C9 and CYP2D6.

All the major furanocoumarins are necessary for the maximal inhibition of CYP3A4 activity observed in GFJ. Each furanocoumarin contributes to the GFJ-drug interaction due to either stronger CYP3A4 inhibitory potency (like dimers GF-I-1 and GF--I-4) or higher natural abundance (like DHB and GF-I-2) (17, 18).

In conclusion, GFJ - drug interactions are caused by additive or synergistic effects of several flavonoids and furanocoumarins in the juice rather then a single potent component (22)

It is interesting to note that related citrus fruits (sweeties, pummelo and sour orange) which contain furanocoumarins are also susceptible to drug interactions. For example, sweetie is a stronger inhibitor of CYP3A4 than GFJ. Kim et al., 2006 (23) reports that commercial black mulberry fruit juice inhibits CYP3A-catalyzed midazolam 1'-hydroxylation suggesting that a mechanism-based inhibitory component is present in these fruit juices as in the case of GFJ. Seville orange juice with DHB and GF-I-2 at half level than GFJ showed similar effect on human CYP (17, 18).

More, residues prepared from star fruit, pomegranate and common papaw significantly inhibited CYP3A4 activity in comparison with white grapefruit juice (control). No significant inhibition was noted with valencia orange, mango, kiwi fruit, dragon fruit or passion fruit (24).http : //www.power netdesign.com/grapefruit/references/index.htm - ref131

b) **P-gp** is an adenosine 5'-triphosphate--dependent efflux pump encoded by the mul-

tidrug resistance (MDR) 1 gene located on the luminal surface of epithelial cells of the small intestine, the bile canalicular membrane of the liver and the proximal tubule of the kidney (5). In addition to GFJ, orange juice and pomelo juice also have been shown to inhibit the activity of P-gp *in vitro* which results in increase blood levels of the drug substrate (4). Okura et al., 2008 (1) reports that GFJ potentiates the antinociceptive effect of morphine through inhibition of intestinal P-glycoprotein.

c) **MRP2** is a efflux protein closely related to Pgp in terms of its expression and function (13).

d) **OATP-B** is a transmembrane sodium- and ATP - independent transporter present in the intestinal mucosa which promotes uptake of drugs into the enterocytes. GFJ inhibition of OATP results in reduced blood levels of the drug substrate (25). There are authors who consider that orange juice (and apple juice) decrease the bioavailability of fexofenadine through an inhibition of the influx transporter OATP (6, 26, 27). Among GFJ components, naringenin and naringin inhibit the OATP-B–mediated uptake of estrone-3-sulfate into human embryonic kidney cells and interact with simvastatin and saquinavir in *in vitro* experiments (11).

e) Recent data indicate that GFJ also decreases the **esterase** activity leading to enhancement of exposure to the active drugs in rats (28). In rat and human hepatic or gut fractions and rat gut lumen, GFJ inhibited the hydrolysis of enalapril and lovastatin, which are known to be metabolized principally by esterases, lovastatin being metabolized also by CYP3A4. The oral bioavailability of lovastatin in humans was increased 15-fold by GFJ (11).

Unfortunately, there are no routine clinical tests available to estimate the extent of pharmacokinetic interaction before exposure (5). The human intervention trials examining the pharmacokinetic interaction of GFJ revealed a great inter-individual variability, where subjects with the highest content of CYP3A4 showed the largest reduction of this enzyme after the consumption of grapefruit (4).

There are several factors associated with greater risk of developing side-effects such as :

- pre-existing medical conditions,
- elderly patient (multiple medication and reduced autonomic responsiveness) (5),
- consumption of high doses of a susceptible drug together with GFJ for the first time (sudden decrease of intestinal CYP3A4 activity),
- severe liver disease (higher importance of intestinal metabolism),
- consumption of drugs with narrow therapeutic index and metabolized by CYP enzymes (16)
- administration of drugs with low bioavailability with other inhibitors of cytochrome P450.

Physicians and pharmacists should be aware of the possibility that some drugs (anti-arrhythmics - amiodarone ; hypnotics - diazepam ; calcium channel blockers - felodipine, nicardipine, nifedipine ; anti-convulsant - carbamazepine ; immune modulators - cyclosporine, hormons - ethinyl estradiol, HMG-CoA reductase inhibitors - atorvastatin, lovastatin, simvastatin ; corticosteroids - methylprednisolone ; macrolide antibiotics - erythromycin etc.) can interact with GFJ and inform the patients about it. Also, in order to facilitate knowledge sharing, regulatory agencies (such as FDA) require some drugs such as cyclosporine, sirolimus, simvastatin, lovastatin, and felodipine to carry a warning label regarding the possibility of an interaction) (4, 29, 30).

In future it is possible to develop grapefruit furanocoumarins as additives to certain drugs in order to improve their oral bioavailability and reduce the variability. On the other hand, as the pharmacogenetic-based

approach is not such a near reality (31), citrus juice manufacturers can develop GFJs without furanocoumarins, which would reduce the potential for a drug interaction (4, 5).

ACKNOWLEDGEMENTS

The research described here has been supported by CNCSIS grant PN II, ID-1235/ 2007.

2. Institutul de Chimie Macromoleculară "P. Poni" Iaşi

RETICULATE POLYMERS USED IN OBTAINING NEW DENTAL MATERIALS (Abstract) : This paper seeks the characterization of new polymers acrylic cross-linked structure, prepared in the presence of a template that creates the polymer synthesized the property of saving template form. **Material and method** : For carrying out synthesis of polymers reticulate-based on dimethacrylate monomer was left to the mono-, di-and trietilenglicol dimethacrylate. Cross-linked polymerization reaction was initiated with benzoyl peroxide. **Results** : New structures are obtained witch respond to the need to diversify and improve the biomaterials used in dentistry. The materials are chemically thermally and mechanically inert. Reticulate polymers are non-biodegradable and therefore do not produce intoxication and not degrade biological fluids. **Key words** : RETICULATE POLYMERS, TEMPLATE POLYMERIZATION, COMPLETE DENTURES

Asimilarea compuşilor macromoleculari sintetici în medicină şi terapeutică, domenii interdisciplinare, trebuie să răspundă complexităţii problemelor de utilizare ce rezultă din contactul temporar sau de lungă durată al materialelor polimerice cu ţesuturile şi substanţele biologice (1). În acest context, sunt definite ca biomateriale polimerice acei polimeri sau compozite polimerice atestate ca biocompatibile în contact cu biostructurile. Prin crearea de noi polimeri şi noi structuri, ştiinţa materialelor pregăteşte tehnologii noi, o dată cu descoperirea de noi fenomene fizice şi proprietăţi specifice la scară atomică (2). Polimerii reticulaţi, pot fi reţele tridimensionale ale catenelor legate chimic între ele sau pot rezulta în urma legării covalente a catenelor liniare (3).

Cea mai folosită răşină utilizată în stomatologie are ca bază de plecare un monomer (metacrilatul de metil) al cărui polimer are în momentul actual o multitudine de denumiri comerciale (4).

Lucrarea de faţă are ca scop obţinerea şi caracterizarea unor noi polimeri acrilici cu structură reticulată, preparaţi în prezenţa unui templat care crează polimerului sintetizat proprietatea de a memora forma templatului. Aceşti polimeri, denumiţi "inteligenţi" datorită memorării formei templatului îşi găsesc în medicina dentară aplicatibilitate practică (5). O traiectorie importantă este înglobarea vitaminei B_{12} în structura polimerului acrilic în scopul tratamentului aftelor bucale, precum şi în scop profilactic prin eliberarea acesteia în saliva pacientului şi reînglobarea ei prin imersia materialelor în B_{12}.

MATERIAL ŞI METODĂ

Metoda de polimerizare utilizată în acest studiu este o metodă nouă numită polimerizare templată în care am utilizat monomeri prezentaţi în tabelul I.

TABELUL I

Denumire	Structură	Provenienta
Etilenglicol dimetacrilat		Reactiv organic, 98%, Merck.
Monoetilenglicol dimetacrilat (MEGD) unde **R** este $-CH_2-CH_2-$	Dietilen glicol dimetacrilat (DEGD) unde **R** este $-(CH_2)_2-O-(CH_2)_2-$	Trietilen glicol dimetacrilat (TEGD) unde **R** este $-CH_2-CH_2-O-CH_2-CH_2-O-CH_2-CH_2$

Ca şi moleculă templat am folosit ciancobalamina care este forma de vitamină B_{12}, cu utilizare pe scară largă din punct de vedere clinic, datorită disponibilităţii şi stabilităţii acesteia. Este transformată în factori activi în interiorul organismului. Pentru realizarea sintezelor de polimeri reticulaţi pe bază de monomeri dimetacrilici s-a plecat de la mono-, di- şi trietilenglicol dimetacrilat. Reacţia de polimerizare reticulantă (fig. 1), a fost iniţiată cu peroxid de benzoil.

Reţinerea, eliberarea şi reîncărcarea cu materialul templat au fost testate cantitativ cu ajutorul spectroscopiei în UV cu ajutorul unui Spectrofotometru UV-VIZ Specord 200 Analytic Jena. Analizele de degradare termică au fost făcute pe un aparat Paulik-Erdey- Budapest Derivatograf, iar spectrele IR pe un Spectrofotometru Specord M90 Carl Zeiss Jena

REZULTATE ŞI DISCUŢII

Polimerul format în urma legării covalente a catenelor macromoleculare este un polimer reticulat iar legăturile formate se numesc reticulări. Aceşti polimeri se disting prin stabilitatea lor dimensională, termică şi chimică, precum şi prin abilitatea crescută de a păstra informaţia formei lor (memoria formei). Influenţa condiţiilor de preparare a polimerilor reticulaţi ai monomerilor dimetacrilici asupra caracteristicilor produşilor obţinuţi sub formă de perle a fost studiată pe un număr de 6 probe pentru obţinerea cărora s-a variat natura monomerilor şi cantitatea de templat. În tabelul II sunt date compoziţiile polimerilor obţinuţi precum şi câteva caracteristici specifice polimerilor. Un studiu al influenţei cantităţii de templat şi a naturii monomerilor asupra structurilor obţinute trebuie să ţină seama de complexitatea reacţiilor care au loc în timpul reticulărilor monomerilor bisnesaturaţi care participă la reacţie.

Cu cât densitatea polimerului este mai

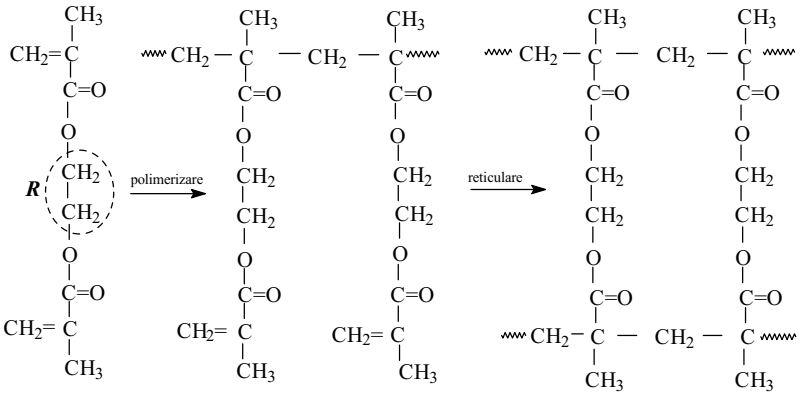

Fig. 1. Polimerizarea-reticularea monoetileglicol dimatacrilatului

TABELUL II
Compoziţia şi proprietăţile polimerilor preparaţi în prezenţa vitaminei B_{12}

	COMPOZIŢIE		PROPRIETĂŢI	
Cod proba	Monomer	Templat %, g	Den-sitate	Stabilit termică T_{max}, ^{0}C
M1	MEGD	25	0,32	425
M2	MEGD	50	0,42	415
D1	DEGD	25	0,41	525
D2	DEGD	50	0,82	530
T1	TEGD	25	0,57	542
T2	TEGD	50	1,00	557

mare, ca atât reticularea este mai puternică. Se observă că materialele polimere cel mai puternic reticulate sunt cele obţinute pe baza de TEGD. Având în vedere faptul că produşii puternic reticulaţi sunt cei mai stabili termic şi chimic, am ales pentru testele de reţinere şi eliberare a templatului proba T2, preparată din monomerul cu catena cea mai lungă şi flexibilă, care în timpul polimerizării permite templatului să rămână în reţeau tridimensională care este heterogenă. Considerând cantitatea iniţială de vitamină B_{12} ca fiind 100%, o cinetică de elibarare a vitaminei pe parcursul a 8 zile, a fost urmărită prin introducerea polimerului într-un pahar cu apă, la temp de 37^{0}C, iar apa a fost schimbată în fiecare zi (fig. 2). Se constată că cea mai mare cantitate de vitamina B_{12} se elibereaza în primele 5 zile, apoi rămâne o cantitate constantă, foarte mică de vitamină, care în condiţiile statice date rămâne constantă.

Structurile preparate prin copolimerizarea reticulantă radicalică a monomerilor mono- şi polinesaturaţi în prezenţa unui templat formează reticulările în jurul tem-

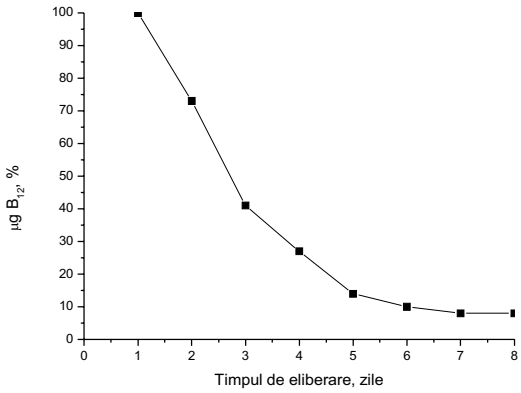

Fig. 2. Eliberarea vitaminei B_{12} în apă, la 37^{0}C

platului, iar eliberarea acestuia lasă goluri în materialul polimeric, goluri care păstrează memoria formei templatului.

Caracterizarea spectrală a polimerilor reticulaţi sintetizaţi a evidenţiat structura complexă a acestor polimeri. Un spectru tipic pentru poli(MEGD) este dat în fig. 4. Se observă existenţa grupărilor vinilice nereacţionate la 1640 cm^{-1} datorate vibraţiilor C=C şi la 950 cm^{-1} datorate =CH_2.

Analiza IR a poli(DEGD) arată structura complexă a polimerului ce conţine benzi de adsorbţie la 1734, 1265, 1160 şi 1060 cm^{-1} atribuite grupării C=O şi grupării -COOR ; la 2890, 2855 cm^{-1} şi la 2960, 2930 cm^{-1} sunt atribuite vibraţiilor simetrice şi asimetrice -CH_3 (fig. 5).

În seria monomerilor M, D, T, creşterea lungimii lanţului dintre cele două grupări nesaturate determină schimbări evidente asupra mecanismului de formare a structurilor macroreticulate. Cu cât distanţa dintre cele două unităţi de ester metacrilic este mai mică, cu atât efectul de împiedicare sterică

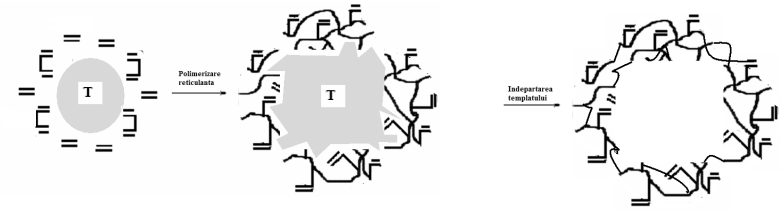

Fig. 3. Modul de formare a polimerului reticulat, în prezenţa templatului

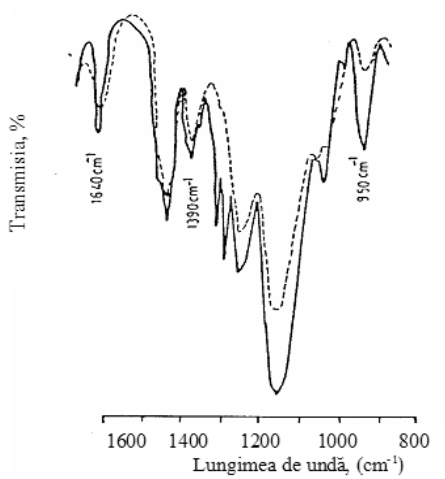

Fig. 4. Spectrul IR al polimerului pe baza de MEGD (—— proba M2 şi _____ proba M1)

creşte şi în consecinţă numărul de reticulări este mai mic. Scăderea masei moleculare medii dintre două reticulări este o consecinţă a creşterii densităţii de reticulare. Cel mai înalt grad de reticulare se observă la poli(TEGD) deoarece monomerul de plecare are lanţul dintre grupările nesaturate cel mai mare. Reacţiile de reticulare sunt favorizate în seria TEGD > DEGD > MEGD în comparaţie cu reacţiile de propagare liniară din cauza efectului excluderii de volum.

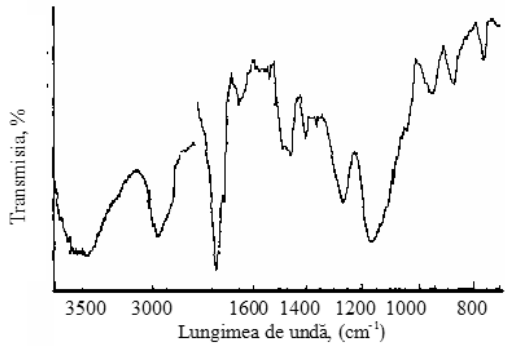

Fig. 5. Spectrul IR al poli(DEGD), proba D1

CONCLUZII

1. Materialele dentare sintetizate fac parte din clasa polimerilor reticulaţi, sinteza lor presupunând unirea macromoleculelor liniare de PMM prin legături covalente cu monomeri monofuncţionali, în cazul nostru MM, sau cu monomeri polifuncţionali, aşa cum este EGDMA
2. Prin metoda polimerizării template se obţin polimeri sintetici cu selectivitate predeterminată care permit difuzia moleculei imprint înăuntrul şi în afara matricei polimere. Locul creat după îndepărtarea templatului se constituie ca "o memorie moleculară indusă", denumită "intellectual cavity", capabilă de recunoaştere selectivă. Polimerii obţinuti în prezenţa templaţilor au o memorie selectivă, reţinând în mod preferenţial produşi cu structură asemănătoare templatului.
3. Întrebuinţarea unor monomeri dimetacrilici, în scopul obţinerii de structuri reticulate polare şi hidrofile răspunde necesităţii diversificării şi îmbunătăţirii biomaterialelor utilizate în stomatologie, cunoscut fiind faptul că polimerii reticulaţi sunt materiale inerte din punct de vedere chimic, termic şi mecanic.

   Polimerii reticulaţi sunt nebiodegradabili şi prin urmare nu produc intoxicări şi nu degradează fluidele biologice.

SOME RELATIONS BETWEEN PHYSICAL GROWTH AND NOURISHMENT. OBSERVATION ON A GROUP OF TEENAGERS FROM CAMPULUNG MOLDOVENESC (Abstract) : The raise and growth of children and youth are processes influenced by the action of internat (inheritance) and external factors (environmental). Among the exterlan factors, nourishment plays an essential role. **Material and method** : The study was made on 369 high school students. There has been made an appreciation of height and weight of these students. There has also been made a nutritional survey on groups of food. **Results** : Height is prevalent high (40.4%) and very high (29.8%) Weight is especially at average (53.8%) and high values (23.1%). The nutritional survey on groups of food shows a raising input of milk, meat (over 100%) at males and females of 11-14 years old, and also of eggs. On the other hand, fish scores a constant shortcoming (-50%). Corny and dried vegetables products are in high quantities whereas the input of fruit is insufficient (over -20%). **Conclusion** : These studies let us know the peculiarities of youth's nourishment, which allow a correct orientation of prevention programs. **Key words** : HEIGHT, WEIGHT, NOURISHMENT

Perioada copilăriei şi adolescenţei se particularizează printr-o creştere şi o dezvoltare intensă (1,2,3). Creşterea este un process cantitativ (de acumulare a substanţei organice), în timp ce dezvoltarea este un proces calitativ (de accentuare a complexităţii structurilor şi funcţiilor). Aceste două procese sunt influenţate de acţiunea unor factori interni (ereditari) şi externi (de mediu). Multă vreme s-a insistat asupra acţiunii unuia din factori, celălalt fiind minimalizat. În prezent, se ştie că aceşti doi factori acţionează concomitent, ajustându-şi reciproc efectele. Un copil ajunge la valorile taliei înscrise în codul genetic doar în condiţiile adecvate de mediu (4,5,6).

Deoarece în cadrul factorilor de mediu, alimentaţia joacă un rol esenţial, ne-am propus realizarea unor aprecieri asupra corelaţiei dintre dezvoltarea fizică şi alimentaţie.

MATERIAL ŞI METODE

Studiul s-a realizat în oraşul Câmpulung Moldovenesc, pe un lot de 369 elevi, în vârstă de 13-17 ani, 292 (79,2%) de sex masculin şi 77 (20,8%) feminin, provenind dintr-o colectivitate în care admiterea se face pe baza selecţiei după anumiţi indicatori de dezvoltare fizică, iar în timpul şcolarizării, exerciţiile fizice sunt incluse în program. Caracteristicile lotului de studiu se referă la aprecierea dezvoltării staturo-

-ponderale (talie, greutate), urmată de încadrarea în clase sigmatice (foarte mică, mică, medie, mare şi foarte mare).

Ancheta alimentară s-a realizat prin metoda statistică, pe o perioadă de 3 ani, în lunile februarie (A1), mai (A2) şi octombrie (A3). Aprecierea s-a făcut cantitativ, pe grupuri de alimente, iar valorile cuprinse între ±10% din normă au fost considerate normale (7, 8). Prelucrarea şi interpretarea datelor s-a realizat folosind testul Pearson.

REZULTATE ŞI DISCUŢII

1. Unele caracteristici ale lotului studiat

Talia a fost de nivel mare (40,4%) şi foarte mare (29,8%), lipsind valorile foarte mici sau patologice, situaţie explicată prin selecţie iniţială.

S-au evidenţiat unele diferenţe ale *valorilor dominante*, astfel, la clasa a IX-a au fost prezente cele foarte mari, la a X-a şi a XI-a, cele mari, iar la a XII-a, cele medii. Aceste date permit a se aprecia că şi în condiţii foarte bune de viaţă, copilul ajunge doar la nivelul înscris în codul său genetic.

Comparând *valorile taliei* elevilor din clasa a IX-a şi a X-a, s-au observat diferenţe semnificative statistic ($p < 0,001$), similară fiind şi scăderea observată în cazul comparaţiei dintre clasa a XI-a şi a XII-a ($p < 0,001$) (tab. I).

Analiza greutăţii corporale pentru lotul inclus în studiu a evidenţiat, în special, valori medii (53,8%) şi mari (23,1%) deoarece selecţia la admitere face ca cele foarte

TABELUL I

Distribuţia cazurilor în relaţie cu nivelul taliei

	%	5,1	51,3	29,5	14,1	100,0
Total	*nr. elevi*	5	105	149	110	369
	%	1,4	28,5	40,4	29,8	100,0

*) pentru valorile mai mici de 10, proporţiile sunt orientative

TABELUL II

Distribuţia cazurilor în relaţie cu nivelul taliei

Clasa		Greutate (clasa sigmatică)				Total
		mică*)	medie	mare	f. mare	
A IX-a	*nr. elevi*	0	17	30	51	98
	%	0,0	17,3	30,6	52,0	100,0
A X-a	*nr. elevi*	0	19	32	47	98
	%	0,0	19,4	32,7	48,0	100,0
A XI-a	*nr. elevi*	1	43	29	22	95
	%	1,1	45,3	30,5	23,2	100,0
A XII-a	*nr. elevi*	1	42	18	17	78
	%	1,3	53,8	23,1	21,8	100,0
Total	*nr. elevi*	2	121	109	137	369
	%	0,5	32,9	29,6	37,2	100,0

*) pentru valorile mai mici de 10, proporţiile sunt orientative

mici şi cele patologice să lipsească, iar distribuţia acestora, pe clase şcolare, să aibă o evoluţie particulară (tab. II).

În clasa a IX-a şi a X-a, au fost dominante valorile foarte mari, pe când la a XI-a şi a XII-a, cele medii. Diferenţele între valorile măsurate la clasa a IX-a şi a X-a sunt nesemnificative statistic ($p > 0,05$), iar pentru celelalte clase, nu au fost îndeplinite condiţiile de cazuri minime, astfel că aprecierea nu s-a putut realiza.

2. Aspecte privind componentele nutriţionale

Caracteristicile alimentaţiei au fost apreciate pe grupuri de alimente: lapte, carne, ouă, peşte, grăsimi, produse cerealiere, cartofi, alte legume, leguminoase uscate, fructe, produse zaharoase. În interpretarea rezultatelor, s-au luat în consideraţie recomandările diferite, care apar în relaţie cu grupurile de vârstă şi sex. Consumul de lapte a fost asigurat, în majoritatea cazurilor, în limite normale.

Consumul de lapte. Excepţie face anul 2005 când, în A2 au existat valori de + 22,8% sau +31,5% la sexul masculin şi de +31,5% la feminin, cu valori în uşor exces, care nu ridică probleme deosebite, deoarece laptele bogat în proteine de calitate asigură creşterea normală a tinerilor (tab. III).

Carnea şi preparatele din carne s-au consumat în exces, urmare a particularităţilor activităţilor din această colectivitate, contribuindu-se, astfel, la optimizarea proceselor de creştere şi dezvoltare. La sexul masculin, consumul celor mai mari cantităţi de carne apare la grupul 11-14 ani, iar la cel feminin, aportul a fost dublu şi chiar mai mare la ambele grupuri de vârstă (11-14 şi 15-19 ani) ($p < 0,005$), cu toate că, în mod normal, necesităţile sunt mai mici, comparativ cu sexul masculin (tab. IV).

Ouăle au fost consumate în cantităţi corespunzătoare, în toate cele trei etape anuale şi în cei trei ani luaţi în studiu.

Consumul de peşte a fost deficitar, chiar şi sub 50% din necesar.

Feminin	A1	+563,8	+656,2	+471,4	+563,8	+656,2	+471,4
	A2	+471,4	+471,4	+471,4	+471,4	+471,4	+471,4
	A3	+563,8	+471,4	+471,4	+563,8	+471,4	+471,4

A1 = luna februarie; A2 = luna mai; A3 = luna octombrie

Grăsimile s-au consumat în cantităţi care au depăşit normele la ambele sexe şi la cele două grupuri de vârstă. La sexul feminin, aportul de grăsimi totale a ajuns şi la un nivel dublu faţă de norme (+119,20% în 2007, A2) ($p < 0,005$). Raportul dintre grăsimile animale şi cele vegetale a fost echilibrat.

Produsele cerealiere au înregistrat la sexul masculin, grupul 11-14 ani, un consum care a depăşit necesarul cu 60%, iar la grupul 15-19 ani, cu 30%, pentru ca la sexul feminin depăşirea să fie de 85% la 11-14 ani şi de 65% la 15-19 ani ($p < 0,005$). Deşi acest aport crescut de cereale reprezintă un factor de risc pentru obezitate, elevii din această colectivitate au compensat, datorită programului permanent, de exerciţii fizice (tab. V).

Cartofii au fost consumaţi în cantităţi mari, la sexul masculin depăşind necesarul cu +21,90% (15-19 ani) şi cu +40,20% (11-14 ani), iar la sexul feminin s-au înregistrat niveluri maxime de +105,20% (15-19 ani) şi +128,05% (11-14 ani) ($p < 0,005$).

Leguminoasele uscate (fasolea, mazărea) au fost incluse în meniurile din această colectivitate, depăşind necesarul de 3-4 ori la sexul masculin (11-14 ani) sau de 1,5-2 ori la 15-19 ani, iar la sexul feminin, depăşirea a ajuns şi la 4-6 ori faţă de valoarea normală ($p < 0,005$) (tab. VI).

Consumul de fructe a fost deficitar, ajungându-se până la o carenţă de -60% la întregul lot studiat.

Produsele zaharoase au fost consumate în cantităţi echilibrate la sexul masculin, dar mai crescute la feminin.

CONCLUZII

Dezvoltarea fizică a adolescenţilor incluşi în lotul studiat a fost foarte bună, datorită modulul de alimentaţie impus de selecţia practicată la intrarea în colectivitate. Talia şi greutatea corporală au înregistrat valori normale, încadrate în clase sigmatice. Alimentaţia evaluată statistic doar pe grupuri de alimente a evidenţiat un consum echilibrat pentru lapte; carnea a fost asigurată în

cantităţi aproape duble faţă de necesar ; în schimb, consumul de peşte a înregistrat un deficit constant de până la 50% din necesar. Produsele cerealiere au depăşit constant necesarul, iar leguminoasele uscate au fost asigurate în cantităţi mari, comparativ cu fructele care au înregistrat un deficit constant.

Rezultatele studiului pot permite cunoaşterea caracteristicilor generale ale alimentaţiei, într-o anumită colectivitate, creând astfel posibilitatea orientării preventţionale a programelor nutriţionale.

NOUTĂŢI

MYCOPHENOLATUL MOFETIL LA COPIII CU SINDROM NEFROTIC STEROID/CICLOFOSFAMID REZISTENT

Un grup de autori brazilieni îşi propune în acest studiu să evalueze rezultatele terapiei cu Mycophenolatul mofetil (MMF) la copiii cu sindrom nefrotic idiopatic (ISN) care s-a dovedit a fi atât steroid cât şi ciclofosfamid-rezistent. Tratamentul a fost urmat minimum 6 luni iar datele înregistrate au sumat peste 2 ani de urmărire. Copiii au fost împărţiţi în 2 grupuri : grupul 1 (34 copii) a cuprins copii care au primit ciclosporină A (CsA) înainte de iniţierea terapiei cu MMF ; grupul 2 (18 copii) a cuprins pacienţi care au primit numai MMF. În grupul 1, remisiunea completă sau parţială a fost înregistrată la 7 (20,6%) respectiv 13 (38,6%) pacienţi. Nu s-a obţinut răspuns terapeutic la 14 copii (41,2%). În grupul 2, remisiunea completă sau parţială a fost prezentă la 5 (27,8%), respectiv şase (33,3%) copii. Fără răspuns terapeutic au fost 7 copii (38,9%). Opt pacienţi au dezvoltat boală renală cronică. Cele mai întâlnite efecte secundare au fost tulburări gastrointestinale (11 cazuri, 21%), infecţii recurente severe (1 caz, 1,9%). MMF s-a dovedit eficient terapeutic n 59, 5% din cazuri. Aceste efecte favorabile nu au fost confirmate în studiile pe termen lung după întreruperea tratamentului. Analiza statistică a rezultatelor studiului prezentat de autorii brazilieni cu privire la terapia cu MMF nu relevă o diferenţă semnificativă între rezultate la copiii care au primit anterior CsA sau cei care au primit direct MMF (Raposo de Mello V, Rodrigues MT, Mastrocinque TH et al. Mycophenolate mofetil in children with steroid/cyclophosphamide-resistant nephrotic syndrome. *Pediatr Nephrol* 2010 ; 25 (3) : 453-460).

EFECTUL ANTIMICROBIAN AL LASERULUI CU MIEZ DE ERBIUM ASUPRA *STREPTOCOCCUS MUTANS*. STUDIU *IN VIVO*

Irina Costache, I. Dănilă
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină Dentară
Disciplina de Dentistică Preventivă

THE ANTIMICROBIAL EFFICACY OF AN ERBIUM LASER ON *STREPTOCOCCUS MUTANS*. *IN VIVO* STUDY (Abstract) : This study was conducted in order to demonstrate the bactericidal effect of an erbium laser (Er,Cr : YSGG) on *Streptococcus mutans*, *in vivo*, at different laser power settings, obtaining sterile enamel surfaces with minimal tissue ablation. The practicians use the laser for the cutting effect on hard tissue to eliminate all the infected and affected enamel and dentine, without collateral damage on the pulp and for its bactericidal effect on cariogenic bacteria. **Material and method** : The study group included 132 superficial carious lesions, on 66 patients with ages between 6 and 20 ; a two-year study (January 2006 – November 2008) performed in a private practice. The carious lesions were ablated with an erbium laser with two types of tips. A sample of occlusal plaque was taken using a sterile swab, soaked in normal saline solution (before and after the preparation). **Results** : Before the laser treatment, the percentage with high counts of *Streptococcus mutans was* 70% and low counts 30% ($\chi^2 = 26,16$; $p < 0,01$). At the laser power of 4,5 watts, the zirconium tip (Z6) had a higher number of sterile culture (96,3%). The numbers of sterile cultures were higher at the laser power of 5 watts, with both tips : zirconium and sapphire, the percentage being equal : 91-92%. **Key words** : LASER THERAPY, SUPERFICIAL CARIOUS LESIONS, STREPTOCOCCUS MUTANS

ASSESSMENT OF *IN VITRO* ANTIOXIDANT ACTIVITY OF SOME NEW FERULIC ACID DERIVATIVES

ASSESSMENT OF *IN VITRO* ANTIOXIDANT ACTIVITY OF SOME NEW FERULIC ACID DERIVATIVES (Abstract): **Aim:** The *in vitro* antioxidant potential of new thiazolidin-4-one derivatives of ferulic acid was evaluated according to the total antioxidant activity and ferric reducing power assays. **Material and methods:** The ferric reducing power assay was based on the reduction of ferricyanide to ferrocyanide, which form in the presence of ferric chloride a Perl Prussian blue color complex. The total antioxidant activity assay was assessed using phosphomolybdenum method. The results were expressed as effective concentration (EC_{50}) values and ascorbic acid was used as positive control. All determinations were performed in triplicate. **Results**: It was found that the activity of the tested compounds is influenced by the substituents on phenyl ring of the thiazolidine-4-one moiety. The most active compound was **1i,** which contains 2,3-diOH as substituent on phenyl ring. **Conclusions:** A total of 10 new thiazolidin-4-one derivatives of ferulic acid were investigated for their *in vitro* antioxidant activity. The most active compound **1i** (R=2,3-diOH) proved to be about 4 times more active than ferulic acid and comparable to ascorbic acid in both antioxidant assays. **Keywords:** FERULIC ACID, THIAZOLIDIN-4-ONES, ANTIOXIDANT ACTIVITY.

Free radicals, chemical species which contain unpaired electrons, could damage the human cells or tissues and may lead to different physiological disorders. They have been implicated in several diseases including diabetes mellitus, inflammation, cancer, cardiovascular and neurological disorders, aging (1). Antioxidants play an important role in free radical scavenging, being involved in the defense mechanism of the human body, thus providing protection against infections and degenerative diseases (1, 2).

Due to its antioxidant effect, ferulic acid could be useful in the prevention and treatment of several oxidative stress-related disorders, including Alzheimer's disease, diabetes mellitus, cancer, hypertension and atherosclerosis (3).

One the other hand one of the most studied classes of heterocyclic compounds is the thiazolidin-4-ones due to their important biological effects: anti-inflammatory (4, 5), antioxidant (6, 7), antimicrobial (4), analgesic (5), antitubercular (8) and antitumor (7) effects.

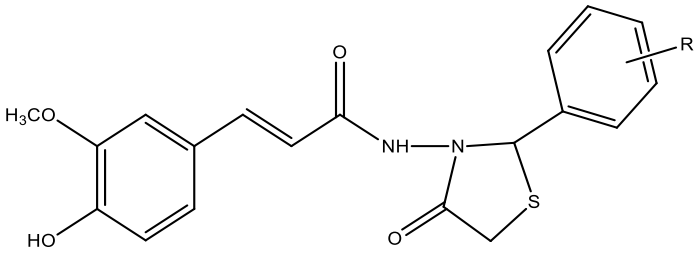
In order to improve the antioxidant effects of ferulic acid, new thiazolidin-4-one derivatives were synthesized. The synthesis of these new derivatives and their spectral characterization have been presented in our previous paper (9). The goal of this study was to evaluate the *in vitro* antioxidant potential of new thiazolidin-4-one derivatives of ferulic acid.

MATERIAL AND METHODS

Chemistry. The structure of the tested compounds, thiazolidin-4-one derivatives of ferulic acid, is presented in tab. I.

TABLE I

Thiazolidine-4-one derivatives of ferulic acid (1a-j)



1a-j

Comp	-R	Comp	-R
1a	-H	**1f**	-OH(2)
1b	-Cl(4)	**1g**	-Cl(2,6)
1c	-F(4)	**1h**	$-N(CH_3)_2(4)$
1d	$-NO_2(4)$	**1i**	-OH(2,3)
1e	$-NO_2(2)$	**1j**	$-OH(4),-OCH_3(3)$

The reagents used for antioxidant assays (ammonium heptamolybdate, potassium ferricyanide, ferric chloride, sodium dihydrogen phosphate, disodium phosphate, trichloroacetic acid, dimethylsulfoxide – DMSO, sulfuric acid) were purchased from Sigma Aldrich Company and Fluka Company.

The total antioxidant activity assay was assessed using phosphomolybdenum method according to the procedure described in the literature (6) with minor modifications. The method is based on the reduction of Mo(VI) to Mo(V) by the tested compounds followed by the formation of green phosphate/Mo(V) complex at acid pH. The samples were dissolved in DMSO in order to obtain a stock solution of 2 mg/mL concentration, from which different volumes (10 µL, 20 µL, 40 µL, 60 µL) were measured and completed with DMSO up to 200 µL. Over these samples 2 mL of the reagent solution (0.6 M sulfuric acid, 28 mM disodium hydrogen phosphate, and 4 mM ammonium heptamolybdate) were added. The samples were incubated at 95°C for 90 min, cooled at room temperature and centrifuged at 4600 rpm for 15 min. The supernatant was separated and the absorbance was measured at 695 nm using a blank (200 µL DMSO and 2000 µL reagent solution) (10). For each sample the effective concen-

tration (EC_{50}) was calculated and expressed in µg/mL. A low EC_{50} value indicate a higher total antioxidant capacity. Ascorbic acid (AA) was used as positive control being processed in a similar manner as the samples. All determinations were performed in triplicate and the values are expressed as mean ± SD (11).

The ferric reducing power assay is based on the reduction of ferricyanide to ferrocyanide in the presence of antioxidants with electron-donating abilities, which form in the presence of ferric chloride a Perl Prussian blue color complex. The compounds were tested at four concentrations (0.25 mg/mL, 0.5 mg/mL, 1 mg/mL, 2 mg/mL). To 1 mL sample of each concentration 1 mL of phosphate buffer (pH 6.6) was added. The reaction was then initiated by the addition of 1 mL of potassium ferricyanide 1%, after which the samples were incubated at 50°C for 20 min and the reaction was completed by the addition of 1 mL trichloroacetic acid 10%. The samples were centrifuged at 4500 rpm for 15 min. To 1 mL of supernatant 1 mL of double distilled water and 0.2 mL of ferric chloride 0.1% were added. After 5 min, the absorbance was measured at 700 nm using a blank prepared similar to the sample, which contained 1 mL DMSO instead of 1 mL sample (10). The results were expressed as EC_{50} values (mg/mL). A small EC_{50} value indicated a higher reducing power (12, 13). Ascorbic acid (AA) was used as positive control being processed in a similar manner as the samples. All determinations were performed in triplicate and the values were expressed as mean ± SD (11).

RESULTS AND DISCUSSION

Total antioxidant activity. The EC_{50} values of the tested compounds are presented in tab. II. As it can be seen, the most active compound was **1i** (R=2,3-diOH), with EC_{50} = 6.60 ± 0.12 µg/mL, which means that it is about 4 times more active than ferulic acid (EC_{50}=26.64 ± 0.01 µg/mL) and comparable with ascorbic acid (EC_{50}=5.12 ± 0.17 µg/mL) at the same concentration. A good antioxidant activity also showed **1j** (R=4-OH,3-OCH_3, EC_{50}=22.76 ± 0.26 µg/mL) and **1a** (R=-H, EC_{50}=23.06 ± 0.02 µg/mL), their activity being comparable with the activity of ferulic acid.

TABLE II

Total antioxidant activity (EC_{50} µg/mL) of the ferulic acid thiazolidin-4-one derivatives (1a-j)

Comp	EC_{50} µg/mL	Comp	EC_{50} µg/mL	Comp	EC_{50} µg/mL

FA – ferulic acid; AA –ascorbic acid; Data are mean ± SD (n = 3, p<0.05)

Ferric reducing power. As it can be seen in tab. III, the most active compound was **1i** (R=2,3-diOH), with EC_{50} = 0.0899 ± 0.01 mg/mL, which means that it is about 4.2 times more active than ferulic acid (EC_{50}=0.3812 ± 0.09 mg/mL) and comparable with ascorbic acid (EC_{50}=0.0516 ± 0.01 mg/mL) at the same concentration. A good antioxidant activity also showed **1h** (R=4-$N(CH_3)_2$, EC_{50}=0.2571 ± 0.04 mg/mL), **1d**

(R=4-NO_2, EC_{50}=0.2937 ± 0.02 mg/mL) and **1e** (R=2-NO_2, EC_{50}=0.3357 ± 0.09 mg/mL), their activity being comparable with the activity of ferulic acid.

TABLE III

Ferring reducing power (EC_{50} mg/mL) of the ferulic acid thiazolidin-4-one derivatives (1a-j)

CONCLUSIONS

In this study a total of 10 new thiazolidin-4-one derivatives of ferulic acid were investigated for their *in vitro* antioxidant activity using the total antioxidant activity and the ferric reducing power assays. The most active compound was **1i,** a thiazolidine-4-one derivative of ferulic acid that has 2,3-diOH as substituent on phenyl ring, this compound being more active than ferulic acid in both antioxidant assays. It is also noted that the activity of this compound was comparable to ascorbic acid used as positive control. These data encourage us to continue these *in vitro* and *in vivo* investigations.

NEWS

RELAPSING POLYCHONDRITIS AND CARDIOVASCULAR INVOLVEMENT

It is well known that autoimmune diseases are characterized by an early atherosclerosis and cardiovascular events. Relapsing polychondritis is a rare inflammatory disorder that affects cartilaginous structures from the nose, ears, larynx and trachea. The cardiovascular involvement appears in 4 to 6% of patients in the form of aortic insufficiency and aortic aneurysm. All the cardiovascular events are associated with an increased mortality. The combination of aortitis and coronary ostial lesion is extremely rare and the decisive role in establishing the diagnosis is owned by the PET-CT scan. (Gavin Sugrue, Laura Durcan, Leann Bell, Ferdia Bolster, Suzanne Donnelly, Eoin Kavanagh. Unsuspected Cardiovascular Involvement in Relapsing Polychondritis A Case of Aortitis With Critical Coronary Artery Stenosis Secondary to Relapsing Polychondritis. *Circ Cardiovasc Imaging*. 2014;7:409-411).

IN VITRO MEASUREMENT OF TOTAL ANTIOXIDANT CAPACITY OF CRATAEGUS MACRACANTHA LODD LEAVES (Abstract): *Crataegus macracantha Lodd*, family *Rosaceae,* is a very rare species in Europe, and unlike *Crataegus monogyna* is less investigated for pharmacologic activity**. Aim:** To analyze the ability of the lyophilisate of extract obtained from leaves of *Crataegus macracantha Lodd* (single plant at the Iaşi Botanical Garden) to capture free radicals *in vitro*. **Material and methods:** The lyophilisate obtained in Department of Pharmacognosy, Faculty of Pharmacy, "Grigore T. Popa" University of Medicine and Pharmacy Iaşi. The decreased absorbance of chromophore chlorpromazine radical cation in the presence of the lyophilized solutions was studied spectrophotometrically. The indicator radical cation, obtained by oxidation of chlorpromazine by potassium persulfate, has the maximum absorbance at 525 nm. Ascorbic acid was used as a standard antioxidant. **Results:** The absorbance of radical solution was determined after the addition of a certain amount of lyophilisate at different time intervals. The antioxidant activity was calculated using the calibration curve obtained by plotting the variation in radical solution absorbance depending on ascorbic acid concentration. For each ascorbic acid concentration the area under the curve was calculated from plotting the percentage inhibition of the absorbance at two pre-established time intervals. **Conclusions:** The results confirm the antioxidant activity of the leaves of *Crataegus Macracantha Lodd* and by optimizing the proposed analytical methods the antiradical activity can be quickly evaluated with minimal reagent consumption. **Keywords:** ANTIOXIDANT ACTIVITY, CHLORPROMAZINE RADICAL CATION, SPECTROPHOTOMETRIC ANALYSE.

The interest in natural antioxidants, aimed at reducing the harmful action of free radicals on the human body has been steadily increasing. In this context, various methods for assessing the antioxidant activity of plant products in view of their use in pharmaceutical, food, cosmetics industries etc. have been developed (1-4). *Crataegus macracantha Lodd*, *Rosaceae* family, is a very rare species in Europe, and unlike *Crataegus monogyna*, is less studied pharmacologically.

The aim of this study was to analyze the ability of the lyophilisate obtained from leaves of *Crataegus macracantha Lodd* (single plant at the Iaşi Botanical Garden) to capture free radical cations resulting from oxidation of chlorpromazine by potassium persulfate ($CP^{\bullet+}$). These chromophore radicals show maximum absorbance at 525 nm. The color of radical solution is diminished by the presence of antioxidants. Ascorbic acid was used as a standard antioxidant.

MATERIAL AND METHODS

The lyophilisate was obtained at the Department of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy "Grigore T. Popa" - Iaşi as follows: 10 g of plant product (leaves) was treated with 100 mL of 70% methanol (v/v); the mixture was stirred for one hour (FALC F-30 ST magnetic stirrer), filtered, concentrated (Rotavapor, BUCHI R-210) and lyophilized (UNICRYO TFD 5505 freeze-dryer).

Of the 10g of plant product 2.62g of crude extract were obtained.

To determine the antioxidant activity the decrease in absorbance of pre-formed radical cation solution ($CP^{\bullet+}$) depending on the amount of lyophilisate was measured spectrophotometrically.

The spectrophotometric measurements were made with a Hewlett Packard 8453 UV-VIS spectrophotometer equipped with multi-diode detector.

Preparing the chlorpromazine radical cation. Chlorpromazine (CP) was oxidized in acidic environment (HCl) by potassium persulfate ($K_2S_2O_8$), forming a radical cation ($CP^{\bullet+}$) with maximum absorbance at λ = 525 nm. For the preparation of the radical 1 mL of 0.01 M chlorpromazine maleate solution was treated with 8.5 mL of 1 M hydrochloric acid and 0.5 mL of 0.001M potassium persulfate solution.

The optimum time interval for the use of radical solution was 20-40 minutes after the addition of potassium persulfate. During this time interval the absorbance of radical solution remained constant.

Sample preparation. About 0.05 g lyophilisate (a) was weighted and dissolved in 10 mL of distilled water. After 30 minutes the resulting suspension was filtered and the obtained solution was diluted with distilled water to final volume of 25 mL.

Working method. To 2 mL radical solution was added a certain amount of lyophilisate solution (v) diluted to 1 mL with distilled water. The absorbance of the solution was measured 10 and 20 minutes after the start of reaction, at λ = 525 nm, 1 cm cuvettes, against water.

The antioxidant activity of the analyzed samples was expressed as molar equivalents (micromolar) of ascorbic acid/gram dry plant product. For this, we used the calibration curve obtained by plotting the variation in absorbance of radical solution depending on the concentration of the standard antioxidant - ascorbic acid (fig. 1).

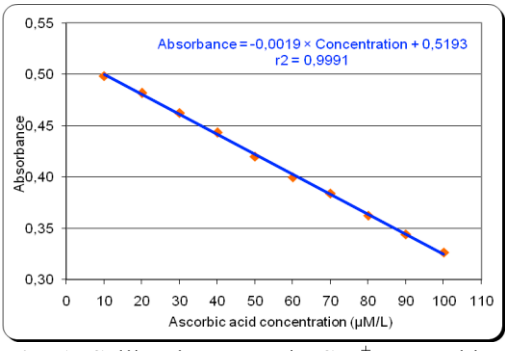

Fig. 1. Calibration curve in $CP^{\bullet+}$ – ascorbic acid system

The method was validated for the linear range of 10-100 μM/L ascorbic acid (5).

RESULTS

For the analyzed samples, the concentration in ascorbic acid was calculated using the straight line equation of calibration depending on the absorbance of freeze-dried solution ($C_{calculated}$). As the final volume of freeze-dried solutions was 1 mL,the concentration of each sample was C = $C_{calculated}$/1000.

Then the result was related to 1 gram dried plant product, taking into account the dilutions made. Measurements were made at 10 minutes (tab. I) and 20 minutes after the start of reaction (tab. II).

				SD	**2.2983**
				RSD	**4.1972%**

The values obtained at the two fixed time intervals demonstrate that quenching of radical reaction by antioxidants from natural product is not completed 10

minutes after the start of reaction (fig. 2).

For this reason, measurements at 20 minutes have RSD values within the acceptable range given while measurements at 10 minutes show a slight deviation from the acceptable range.

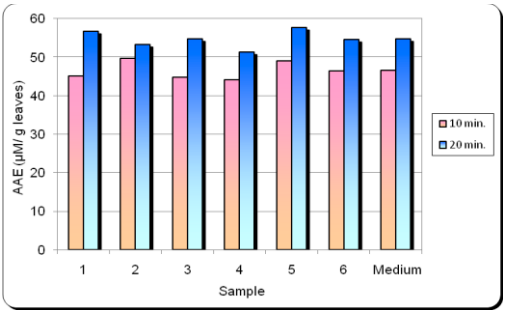

Fig. 2. Micromolar ascorbic acid equivalents (AAE)/1 g *Crataegus macracantha* leaves(10 and 20 minutes after the start of reaction)

In order to eliminate the fluctuations due to changes in absorbance during testing time we used the calibration curve obtained by plotting the area under the curve (AUC) versus ascorbic acid concentration (fig. 3).

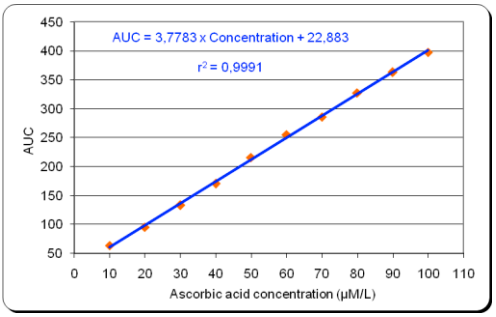

Fig. 3. Area under the curve (AUC) dependent on ascorbic acid concentration

The area under the curve was calculated for each concentration in ascorbic acid (10-100 µM/L) in the graphical representation of the variation of percent inhibition during the fixed time interval (10 minutes and 20 minutes). % Inh = Ar - As / Ar.100, where As–sample absorbance; A_r - radical absorbance (6)

The values obtained by this calculation method for the analyzed samples are given in Table III. The percent inhibition was calculated with Ar = 0.53103.

DISCUSSION

It has been demonstrated that the radical quenching reactions are influenced by the activity of the antioxidant (its reducing

power), its concentration and the time point selected for carrying out the determinations (7-9).

Thus, antioxidants with a higher reducing power will react faster with the radicals, while in case of a decreased reducing power the reaction rate is slower and the time required to complete the reaction of radical quenching will be longer.

The variations in the antioxidant activity of the leaves of *Crataegus macracantha Lodd* within 10-20 minutes after the start of reaction is explained by the presence in the lyophilisate of some compounds with a weaker reducing power, acting on radicals with lower speed.

The values obtained when evaluating the antioxidant activity from the calibration curves AUC- standard antioxidant concentration are situated between the two limit values (from 10 and 20 minutes respectively), the error of determinations being also below the RSD value of the method.

Determination of AUC is a more accurate criterion for the assessment of total antioxidant activity, because it considers both the antioxidant concentration and reaction time, being a parameter for measuring the ability of the antioxidant to capture free radicals, compared to a standard antioxidant, during a fixed time interval.

CONCLUSIONS

Our results confirm the antioxidant activity of the leaves of *Crataegus macracantha Lodd* and by optimizing the proposed analysis methods the antiradical ability of this less studied species can be measured with minimum reagent consumption and in a short period of time. Its antioxidant properties justify a more thorough research aimed at making full use of this plant in therapy.

IMPLICATIONS OF THE RANK/RANKL AXIS IN THE BONE PATHOLOGY (Abstract): The receptor activator of NF-κB (RANKL) is a member of the tumor necrosis factor (TNF) super-family. Its receptor, RANK, is expressed on the membrane surface of the dendritic cells (DC). RANKL, expressed by mesenchymal cells on bone tissue level, is a direct regulatory factor of osteoclasts formation and of the bone turnover. T and B lymphocytes express RANKL following their activation. On biologic level, various bone disease are mediated by RANKL. Moreover, the proinflammatory cytokines such as interleukines (IL-1, IL-6, TNFα) present high levels in periodontal impaired tissues. The current literature describes an interaction between these cytokines and RANK/RANKL/OPG system. High levels of IL-1 and TNFα determine high levels of RANKL and, consequently, initiate the osteoclastogenesis. Current studies are focused on the research of the inhibitory effects for RANKL in patients with post-menopausal osteoporosis, rheumatoid arthritis, prostate cancer, breast cancer and multiple myeloma. **Keywords**: RANK, RANKL, OSTEOPOROSIS, PERIODONTITIS, INHIBITORY THERAPY.

The receptor activator of NF-κB (RANKL) was cloned in 1997 as a member of the tumor necrosis factor (TNF) superfamily (1). Its receptor, RANK, is expressed on the membrane surface of the dendritic cells (DC). The main role of RANKL, as an osteoclastogenetic factor, was discovered in 1999 (2). RANKL, expressed by mesenchymal cells on bone tissue level, is a direct regulatory factor of osteoclasts formation and of the bone turnover. Furthermore, T and B lymphocytes express RANKL following their activation (3, 4). Therefore, the activation of the immune system can induce abnormal bone loss.

Signaling pathways of RANK in the osteoclastic differentiation. Since the discovery of the RANK/RANKL axis, the signaling pathways stimulated by RANKL were extensively studied. RANK, which is coded by the *Tnfrsf11a* gene, is induced by M-CSF on the osteoclastic precursor cells, stimulating their proliferation. The binding of RANKL initiates the trimerization of RANK and activates the intracellular signaling (5). The RANK/RANKL signaling is inhibited by osteoprotegerin (OPG), coded

by *Tnfrsf11b* gene; OPG binds to RANKL and prevents its interaction to RANK (6). OPG is expressed on various bone and immune cells (osteoblasts, LyB, DC) (7). The RANK-RANKL binding determines, besides the trimerization of the receptor, also a rapid recruitment of the associated tumor necrosis factor 6 (TRAF6). RANK interacts with different TRAF molecules (1-3, 5, 6) but only TRAF6 is essential for the osteoclastic function (8).

RANK activation leads immediately to the phosphorylation of the ITAM immune receptor in DAP12 protein and in the Fc subunit of the c receptor (FcRc). DAP12 and FcRc are intracellular adaptor molecules which interact with immunoglobulin-like receptors (such as osteoclast associated receptor – OSCAR), with the immunoglobulin-like paired receptor (PIR-A) and with the trigger receptor expressed by myeloid cells 2 (TREM2), which are expressed on the cellular membranes of the osteoclastic precursors (9). These are known as co-stimulatory receptors due to the fact that they are essential for the osteoclastogenesis.

The osteoclast differentiation and their activation is a complex process which depends on a sustained and coordinated activation of the transcription factors, among which we can find c-Fos, NF-κB şi NFATc1 (10). A large part of the regulatory mechanisms and of the pathways which orchestrate this complex cascade was initially identified in immune cells. Therefore, it extremely clear that the immune and bone cells have in common various molecules, such as cytokines, transcription factors and protein kinases.

Particularities in osteoporosis impairment. Osteoporosis is a chronic and frequent disease, the result of a lack of balance between the bone formation and bone resorption, associated to a high risk of pathologic bone fractures and an impaired quality of life. One third of the female patients and one fifth of the male patients, with the age beyond 50 years old would suffer osteoporotic fractures (11). The associated risk for hip, forearm and vertebral fractures is approximately of 40%, similar to the risk for cardiovascular diseases (12).

The incidence of osteoporosis is higher for the female patients (80%), when compared to male patients (20%). There are two phases of primary bone loss in females. The first step includes the trabecular bone loss as a result of the estrogen deficiency initiated by the menopause onset, which lasts 4-8 years and which is characterized by high bone loss and a reduction in the bone formation. The second step implicates a slower trabecular and cortical bone loss, as a result of a diminished bone tissue formation. In males, the bone loss is produced in a slower rate, as a result of the low levels of bioavailable testosterone and estrogen.

B lymphocytes were associated to low concentrations of sexual hormones and bone loss. The ovariectomy stimulated the formation of LyB precursors on medullar level (13). The estrogen therapy in ovariectomized mice prevented the stimulation of the B lymphopoiesis, completely blocking the bone loss. The ovariectomy does not stimulate an exaggerated expression of RANKL on LyB but, more precisely, there is a correlation between the bone loss and a high number of LyB which express abnormal RANKL levels (14).

RANKL expression in case of periodontal impairment. The periodontal disease is an infectious and inflammatory disease. The presence of the bacteria on the root surfaces generates a specific and non-specific immune response of the host. The

relationship between the defense cells and bone cells offers an immunological image of the periodontitis pathogeneity. The pro-inflammatory cytokines (such IL-1, IL-6, TNFα) present high levels in periodontal impaired tissues. The current literature describes an interaction between these cytokines and RANK/RANKL/OPG system. High levels of IL-1 and TNFα determine high levels of RANKL, and consequently initiate the osteoclastogenesis (15).

It was demonstrated that RANKL mRNA is very high in inflammatory cells in patients with severe periodontitis, when compared to the levels of moderate periodontitis or healthy patients, indicating a possible involvement of RANKL in alveolar bone destruction. Immune histochemistry techniques demonstrated a significant expression of RANKL protein in periodontal tissues, associated to macrophages and lymphocytes in chronic periodontitis patients (16). LyT and LyB present in the inflammatory sites have an essential role as a trigger of bone resorption by RANKL-dependent mechanisms. Lymphocytes, especially LyT subsets, are involved in stimulations or inhibitions of RANKL mediated bone resorption; type 1 T helper cells will favor the bone resorption, while regulatory LyT will suppress LyTh1 mediated bone loss.

A possible connection between systemic osteoporosis and alveolar bone loss was suggested by the fact that osteoporosis will determine a stimulation of pro-resorptive cytokines on bone and medullar level, higher levels of circulatory Il-1, Il-6 or TNF-α. Even small risings in the levels of these cytokines will initiate the cytokine-prostaglandine cascade (prostaglandins – matriceal metalloproteinases – RANKL) on periodontal level (17). In a study conducted on mice with osteoporosis and ligature induced periodontitis it was demonstrated this cumulative effect of these two chronic diseases; the mice presenting both osteoporosis and periodontal disease manifested significantly higher osteoclastic activity and RANKL than those with only one of the diseases (18).

New therapeutic approaches – RANKL inhibition. Denosumab is a monoclonal antibody of IhH2 with high affinity and specificity which binds human RANKL, thus inhibiting its interaction with RANKL and interfering with the osteoclastogenesis steps. The single dose denosumab determined rapid, profound and sustained inhibitions of the RANKL mediated resorption (up to 80%), reflected by reduced biochemical markers of the bone resorption (N-terminal seric telopeptide of collagen I – NTx and NTx/urinary creatinine) (19). This rapid suppression of osteoclasts suggests that mature and active osteoclasts are immediately influenced by denosumab. The inhibition of resorption by denosumab is dose-dependent, maximal at one month and sustained for 6-9 months for doses higher than 1mg/bkg.

On biologic level, various bone disease are mediated by RANKL. Current studies are focused on the research of the inhibitory effects for RANKL in patients with postmenopausal osteoporosis, rheumatoid arthritis, prostate cancer, breast cancer and multiple myeloma (20).

The RANKL inhibition presents a series of advantages when compared to the anti-resorptive therapy with bisphosphonates. The RANKL inhibition can block the bone lesions which, in practice, are refractory to bisphosphonates (like arthritic bone erosions). The RANKL inhibition can prove to be more active, more efficient and less

expensive than the bisphosphonates.

Regarding the limitations of RANKL inhibition therapy, there are a few aspects which need to be taken into account:

- The adynamic bone disease – is a process in which the profound inhibition of the bone remodelling can lead to microfractures and high bone fragility. Unusual fractures were reported (i.e. on femoral neck) after the prolonged therapy with alendronate (21, 22);

- Immunosuppression: RANK/RANKL signaling was initially identified as a co-stimulatory pathway during the activation of LyT (2). Even though the short term studies failed to demonstrate adverse effects, the possible effects on the immune system must be considered in patients with long term RANKL inhibition therapy (20).

The evolution of the osteoimmunology concept offered the possibility for the development of new therapy approaches, focused on the RANK/RANKL interaction. High affinity monoclonal antibodies (like denosumab) are the treatment of choice in RANKL inhibition. Short term data suggest that such therapy is safer and more efficient in cases of post-menopausal osteoporosis, even more in cases which are refractory to bisphosphonates.

Regarding the particularities of the cases with periodontal disease, the new therapy means must address, above the classical periodontal debridement therapy, also to the immune contribution to the bone resorption. When having a deep knowledge of the host immune response to the bacterial aggression, a re-evaluation of the therapy measures is necessary, with new therapy strategies focused on the cell mediated destruction. Specifically, the approaches of the RANKL production can include the interference with co-stimulatory molecules, which are necessary for the RANKL production, the control of the signaling pathways or the inhibition of RANKL expression on lymphocytes level by controlling the cytokine balance (23). The classical mechanical debridement with scaling and root planning remains the therapy gold standard when confronting with a periodontal patient but the cases must be addressed to a more complex level, with adjunctive therapies which could facilitate the therapy success or even the prophylaxis of the periodontal tissue losses.

HYPOGLYCEMIA INDUCED BY ANTIDIABETIC SULFONYLUREAS

HYPOGLYCEMIA INDUCED BY ANTIDIABETIC SULFONYLUREAS (Abstract): Diabetes mellitus is a major health problem due to its increasing prevalence and life-threatening complications. Antidiabetic sulfonylureas represent the first-line drugs in type 2 diabetes even though the most common associated risk is pharmacologically-induced hypoglycemia. In the development of this side effect are involved several factors including the pharmacokinetic and pharmacodynamic profile of the drug, patient age and behavior, hepatic or renal dysfunctions, or other drugs associated with a high risk of interactions. If all these are controlled, the risk-benefit balance can be equal to other oral antidiabetic drugs. **Keywords**: TYPE 2 DIABETES MELLITUS, SULFONYLUREAS, HYPOGLYCEMIA, SUSCEPTIBILITY FACTORS.

Nowadays diabetes mellitus (DM) has become one of the most challenging health problems due to its remarkable increase in incidence in both developed and developing countries (1, 2). The International Diabetes Federation stated that in 2013 382 million people had diabetes and this number is expected to rise to 582 million in 2035 (3).

At the same time, for researchers DM is still an open subject, both in terms of understanding and elucidating its pathophysiological mechanisms and in developing new drugs for type 2 diabetes with a more advantageous pharmacotoxicological profile.

In terms of biochemistry and pathophysiology, DM is a chronic metabolic disorder characterized by disturbances of carbohydrate, lipid and protein metabolism. This disorder appears to be due to deficiency in insulin secretion by pancreatic β cells, associated or not with insulin resistance in peripheral tissues, leading to elevated blood glucose levels (2, 4, 5).

DM is a silent disease and if undiagnosed or untreated for a long time it can lead to serious macrovascular and microvascular complications. It can be stated that DM has become a life-threatening disease due to its complications, being the fourth leading cause of death in humans (2, 6).

Taking into consideration the fact that an intensive glycemic control is essential in reducing the development and progression of diabetes complications, the pressure to discover new antidiabetic agents has increased and at the moment nine classes of

medications are available for type 2 DM. (4, 7-9). The different mechanisms of action of the various classes of hypoglycemic drugs make combined therapy feasible and give different metabolic and adverse effect profiles (10).

THE PLACE OF SULFONYLUREAS IN THE TREATMENT OF TYPE 2 DIABETES

Hypoglycemic sulfonamides were the first oral antidiabetic agents used in the treatment of type 2 DM (11, 12); they are the first-line medication in patients with moderate diabetes when diet, physical exercise and weight loss do not manage to keep an optimal glycemic control (9, 13).

All these drugs have in common the phenyl-sulfonyl-urea sequence which gives them the hypoglycemic properties; the R and R_1 radicals modulate the pharmacokinetic and pharmacotoxicological profile (14) (fig. 1).

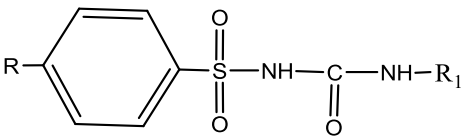

Fig. 1. General chemical structure of hypoglycemic sulfonylureas

Hypoglycemic sulfonylureas act by closing ATP-sensitive K^+ channels with reduction of K^+ efflux and depolarization of β-cells membrane. Consequently, voltage dependent Ca^{2+} channels are opened, Ca^{2+} influx is increased and phosphorylation reactions are stimulated, leading to the release of insulin from pancreatic β-cells (2, 5, 10, 14, 15).

Despite the extensive use of these drugs, recommendations in official guidelines and pathophysiologic plausibility, there are concerns regarding their safety profile (16); the most troubling adverse effects are hypoglycemia (2, 10, 14) and weight gain (2, 10); other risks are hepatotoxicity (4, 10, 17), hematologic dyscrasias (10, 14), myocardial infarction (10, 13, 15, 18), allergic reactions (2, 10), and gastrointestinal disturbances (10).

SULFONYLUREAS-INDUCED HYPOGLYCEMIA

Pharmacologically-induced hypoglycemia is the major risk in patients using sulfonylureas for the treatment of type 2 DM and a major barrier in maintaining a good long-term glycemic control (19). If weight gain is a side effect generally accepted and considered „the price to be paid for normalization of blood glucose" (10), hypoglycemia caused by sulfonylureas is a major concern because of its severe consequences.

It is known that an optimal glycemic control plays an essential role in preventing chronic microvascular complications; achieving this objective without the risk of hypoglycemia is a priority in the early stages of diabetes (8).

Current recommendations advise individualizing the objective of glycemic control based on patient features and diabetes evolution; in young patients without longstanding diabetes and associated comorbidities a strict glycemic control is recommended. This control refers to an HbA1c level less than 6.5%. In older patients with cardiovascular diseases and microvascular complications an HbA1c level of 7% - 8% is considered adequate in order to prevent hypoglycemia (8).

Hypoglycemia can be defined as a condition in which the low blood glucose level exposes the individual to serious damages (8). The most accepted value to define

hypoglycemia is 70 mg/dl because this is the threshold for activation of counter regulatory mechanism in non-diabetic individuals and the superior limit at which the counter regulatory response to hypoglycemia changes (20) (tab. I).

TABLE I
Classification of hypoglycemia depending on severity (8, 20)

Type of hypoglycemia	Characteristics
Severe hypoglycemia	Requires external assistance for recovery
Documented symptomatic hypoglycemia	Typical symptoms and a measured capillary glucose level < 70 mg/dl
Asymptomatic hypoglycemia	Capillary glucose level < 70 mg/dl without typical symptoms
Probable symptomatic hypoglycemia	Typical symptoms of hypoglycemia not accompanied by measurement of capillary glycemia
Pseudohypoglycemia	Symptoms of hypoglycemia with capillary glycemia values > 70 mg/dl

Symptoms. The symptoms of hypoglycemia vary between individuals and they are generated by activation of the adrenergic system and by the direct effect of glucose deprivation on the brain. The release of counter regulatory hormones (glucagon and adrenaline), the adrenergic symptoms and the development of central nervous system dysfunctions are triggered at specific levels of blood glucose. There are 11 most common symptoms experienced during hypoglycemic episodes: sweating, palpitations, shaking, hunger, confusion, drowsiness, strange behavior, difficulty in speaking, incoordination, headache, nausea (19, 21).

Incidence. The incidence of hypoglycemic events in type 2 DM depends on several factors and increases with disease progression, degree of insulin deficiency, as well as in cases of treatment with sulfonylureas and insulin (8). Sulfonylureas cause much more hypoglycemia than it is recognized, with an annual prevalence of severe episodes of 7% (19). Studies reported that up to 20% of sulfonylurea-treated patients experienced symptoms suggestive of hypoglycemia. During the first year of United Kingdom Prospective Diabetes Study at least 30% of glibenclamide-treated patients experienced hypoglycemia. After a follow-up period of 10 years the annual incidence of patients with at least one hypoglycemic event was 11% with chlorpropramide, 17.7% with glibenclamide, and 36.5 % with insulin therapy (16). However, severe hypoglycemic episodes appear to be more prolonged and associated with greater mortality when induced by sulfonylureas than by insulin (22).

Despite differences between the studies, sulfonylurea-induced hypoglycemia has a significant incidence and it is a major concern because of its considerable economic impact on health care system.

Susceptibility factors. Sulfonylurea-induced hypoglycemia is a multifactorial adverse effect where drug features; patient features and patient behavior are intermingled. It is difficult to establish in which proportion each factor leading to hypoglycemia is involved (5).

Regarding drug characteristics, the pharmacokinetic profile of sulfonylureas is relevant, especially their duration of action

which is linked to long-lasting hypoglycemia (23).

It is interesting to note that there is not always a relationship between the duration of action and blood concentrations; sulfonylureas may make the cells more sensitive to insulin and when the concentration is falling, stimulation of insulin secretion can continue and it is difficult to predict for how long the hypoglycemic effect will last (10).

The majority of reported cases of hypoglycemia were on chlorpropamide or glibenclamide (12, 16) which are long-acting sulfonylureas whose metabolism can lead to accumulation. Glipizide, gliclazide and gliquidone are less likely to cause hypoglycemia because they are short-acting drugs and their metabolites are inactive or have minimal hypoglycemic effect (2). Although glimepiride has a long duration of action, there were fewer hypoglycemic reactions compared with glibenclamide, probably due to a better modulation of insulin release (16) (tab. II).

TABLE II

Phamacokinetic profile of some sulfonylureas (10, 14, 23)

Drug	Half-life (h)	Duration of effect (h)	Active metabolites
Tolbutamide	3-5	6-10	-
Chlorpropamide	24-48	27-72	+
Glibenclamide	2-4	20-24	+
Gliclazide	6-15	10-15	-
Glipizide	3-5	6-12	-
Gliquidone	6-10	6-12	-

As to patient features, there are several susceptibility factors leading to sulfonylurea-induced hypoglycemia including age, liver, renal and cognitive impairment (5, 24). The risk of hypoglycemia among elderly patients treated with sulfonylureas is 36% greater than in younger adults; in this group of patients glimepiride and glipizide are preferred due to their less hypoglycemic potential (25). In a study of 57 patients with type 2 DM who experienced glibencamide-induced hypoglycemia, more than 90% were older than 60 years and more than 70% above 70 years (16).

In the elderly patients the elimination half-life is longer for most sulfonylureas and patients older than 60 years are particularly at risk. These drugs are metabolized in the liver and eliminated from the circulation via the kidneys (12); thus, renal and hepatic failures are important contributing factors depending on the drug involved (23).

Hypoglycemia may be difficult to recognize in old patients because the characteristic warning symptoms could be absent or not well interpreted but also in patients on β-adrenergic blockers (10).

Taking these into consideration, the most frequent contraindication for sulfonylureas is the elderly diabetic patient with renal or kidney disease; if prescribed, there are preferred short-acting drugs, with a moderate hypoglycemic effect and without active metabolites (26).

Not only the sulfonylurea is responsible for hypoglycemia, but also the circumstances of drug administrations; reduced food intake, restricted carbohydrate intake, severe or prolonged physical exercise and alcohol consumption are the most common predisposing factors (10, 23).

Finally, another cause of hypoglycemia which cannot be overlooked is represented by drug interactions. Most drugs have been reported to interact with sulfonylureas; these interactions result from changes in the pharmacokinetic profile of sulfonylureas (absorption, displacement from plasma proteins, alterations in their metabolism) or are caused by drugs that affect blood glucose levels (23, 27).

CONCLUSIONS

The treatment of type 2 diabetes mellitus remains a challenge given the necessity to maintain an optimal glycemic control without the risk of hypoglycemia. Despite their increased risk of hypoglycemia, sulfonylureas still occupy a central position in the recommendations of many guidelines.

However, when choosing a specific treatment for diabetes, it is necessary to take account of patient preferences and comorbidities as well as all conditions that may be associated with a sulfonylurea-induced hypoglycemia. If all these procedures are being followed the risk-benefit balance for sulfonylureas is not worse than for others oral hypoglycemic agents.

ASSESSMENT OF THE MICROBIAL LOAD OF SOME MEDICINAL PLANTS COMMONLY USED IN ROMANIA (Abstract): **Aim**: This study aims to assess the microbial load of some medicinal plants (*Matricaria chamomilla, Achillea millefolium, Ocimum basilicum, Calendula officinalis, Tilia cordata, Hypericum perforatum*) commonly used as medicinal teas. **Material and methods**: A total of 24 samples collected from the local market, as well as from the spontaneous flora of Galati County, were analyzed in terms of the total number of germs, the content of coliform bacteria, yeasts and molds, and the presence of specific pathogenic bacteria (*Escherichia coli, Bacillus cereus, Coagulase-positive Staphylococcus, Salmonella* spp.). **Results:** The values obtained for total number of germs, yeasts and molds were in accordance with the limits set by the *European Pharmacopoeia* for plant products to which hot water is added before use. In the case of specific pathogenic bacteria, the presence of *E. coli* was confirmed in 41.66% of the samples, the presence of *Coagulase-positive Staphylococcus* in 16.66% of the samples, and the presence of *Bacillus cereus* in 33.33% of the samples. *Salmonella* spp. was absent in all samples. **Conclusions:** The study highlights a certain microbial load of medicinal plants analyzed, emphasizing the importance of quality control in all stages of production. **Keywords:** MICROBIAL CONTAMINATION, MEDICINAL PLANTS, QUALITY STANDARDS

Medicinal plants have been used since ancient times, modern science today proving many of their therapeutic benefits. Worldwide, there is an increasing interest for products from medicinal plants, so their use is rapidly rising. In these conditions, the quality and safety of the phyto preparations is a major concern for health authorities and consumers (1). Microorganisms from the environment (soil, air, water) can contaminate medicinal and aromatic plants, the process being influenced by various factors: temperature, humidity, but also by the harvesting, storage, processing and marketing conditions. The increase in the degree of contamination during the stages of harvesting, production, transportation or storage may have significant consequences on the appearance, physical characteristics, pharmacological action of the active principles, or the stability of preparations obtained from medicinal plants, but also on the health of

consumers (2, 3, 4, 5). *European Pharmacopoeia* (6) provide specific requirements regarding the presence and the level of microbial contaminants in medicinal plants and phytomedicines. This study aims to assess the quality of some medicinal and aromatic plants, commonly used as medicinal teas in terms of the presence of microbial contaminants: total number of bacteria, the content of coliform bacteria, yeasts and molds, as well as some specific pathogenic bacteria (*Escherichia coli, Bacillus cereus, Coagulase-positive Staphylococcus, Salmonella* spp.).

MATERIAL AND METHODS

Plant material. Six common medicinal species were selected for the study: *Matricaria chamomilla, Achillea millefolium, Ocimum basilicum, Calendula officinalis, Tilia cordata, Hypericum perforatum.* They are common plants, easily available and frequently used in Romania as medicinal tea. For each species three commercial samples from different distributors (A, B and C), and a sample collected from the spontaneous flora in the Galati County were analyzed (tab. I). The commercial samples were purchased in bulk packaged form in September 2012, and the harvesting was done in the period May-September 2012.

TABLE I
Plant material samples

Plant material		Source			
		A	B	C	Spontaneous flora
Flowers	*Matricaria chamomilla*, Asteraceae, chamomille	MC1	MC2	MC3	MC4
	Calendula officinalis, Asteraceae, marigold	CO1	CO2	CO3	CO4
	Tilia cordata, Tiliaceae, linden	TC1	TC2	TC3	TC4
Flowering aerial parts	*Achillea millefolium*, Asteraceae, yarrow	AM1	AM2	AM3	AM4
	Ocimum basilicum, Lamiaceae, basil	OB1	OB2	OB3	OB4
	Hypericum perforatum, Hypericaceae, St. John's Wort	HP1	HP2	HP3	HP4

Sample preparation. The plant material was dried at 600°C in 24 h, and then it was pulverized by grinding and then it was properly labeled (7). For each type of plant product fragments were taken out from different bags, out of which 10 g of triturated sample were weighed, with an equal amount of sterile sand. The test solution was obtained by gradually adding the dilution liquid in an amount 9 times greater than the triturated sample (primary dilution 1/10). If necessary, decimal dilutions were performed successively (the difference between two successive dilutions was 10 times) depending on the degree of assumed contamination.

Assessment of the total number of germs. It was done by using the spread-plate technique. Thus, 0.1 mL of the prepared dilutions were spread on the culture medium (agar, Oxoid, United Kingdom) fused and solidified at ambient temperature. After 48 h of incubation at 30-37ºC, the colonies from the Petri dishes were counted and the total

number of bacteria per g/mL (N) was calculated using the formula:

$$N = \frac{EC}{(n1 - 0.1\ x\ n2) x\ d}$$

where: EC=the sum of colonies counted in all retained plates; n1=the number of plates where between 10 and 300 colonies were counted on the first dilution; n2=the number of plates where between 10 and 300 colonies were counted on the second dilution; d=dilution factor corresponding to the first dilution (7).

Estimation of the total number of coliform bacteria. It was performed using the end point dilution technique (MPN=most probable number). 10 mL of liquid culture medium (Lauryl Tryptose Broth, Oxoid, United Kingdom) was distributed in test tubes with Durham tubes. 1 mL homogenate of each dilution (three successive dilutions were used) was inoculated into each Durham tube. After spreading, they were incubated at 35°C for 48 h. On the basis of the number of positive tubes (gas accumulation in the at least 1/10 of the collector tube height) from the dilutions taken into account, estimation of total coliforms was achieved using the standard MPN table (7).

Estimation of the most probable number of Escherichia coli. It was performed by passing the content of the test tubes considered to be positive for coliform bacteria into two test tubes (one with Lauryl Tryptose Broth and one with Peptone Water), preheated to 44ºC. A strip impregnated with Kovasc reagent was added to determine the presence of the indole. After incubation at 44ºC for 48 h, were considered to be positive those test tubes from the presumptive test corresponding to the test tube with Lauryl Tryptose Broth where gas was produced, and the one where the paper strip inserted in Peptone Water (Oxoid, United Kingdom) turned red. The most probable number was calculated on the basis of the number of tubes in which both reactions were positive (7).

The Bacillus cereus number was determined by using the colony-counting technique. 0.1 mL of each dilution (prepared by successive dilutions of the 10^{-1} dilution inactivated on a water bath, 45 min at 65°C) were spread on the surface of Petri plates with agar (Oxoid, United Kingdom) and defibrinated sheep blood 5% (Cantacuzino Institute, Bucharest, Romania). After 48 h incubation at 30-37ºC, 5 colonies were selected in each plate and the Gram coloration was analyzed, the macroscopic aspect and the biochemical characteristics (the presence of hemolysin) (7).

Determination of the Coagulase-positive Staphylococcus number was performed by using the end point dilution technique (MPN=most probable number). For each sample three successive dilutions were used, and from each dilution (1 mL) series of three test tubes were brought in Chapman liquid medium (Mannitol Salt Broth, Himedia, India), and then incubated for 48 h at 30-37ºC. From each test tube passes were made to the solid Chapman medium (Mannitol Salt Agar, Oxoid. LTD, United Kingdom) distributed into Petri dishes and they were incubated for 24 h at 30-37ºC (7).

Estimation of Salmonella spp. count. 1 mL of incubated pre-enrichment medium (25 g dried plant material mixed with 225 mL broth in an Erlenmeyer flask and incubated to 35°C for 24 h) was inoculated into a tube with 10 mL enrichment medium (Selenite Broth Base, Oxoid, United Kingdom), and it was incubated at 35ºC for 48 h. From the enrichment medium passes were made to the selective medium (Desoxycholate Citrate Lactose Agar, Cantacuz-

ino Institute, Bucharest, Romania), distributed in Petri dishes and they were incubated for 24 h at 35ºC. The suspicious or typical colonies were biochemically tested (7).

Determination of yeasts and molds. The degree of contamination was determined by incorporating a certain quantity of sample (1 mL) in a solid medium (Czapek Dox, Oxoid, United Kingdom) and incubating at room temperature (22-24ºC) for 5 days. The colonies were counted (CFU=colony-forming units/g or mL) (7).

RESULTS AND DISCUSSION

The values of the microbiological load of vegetable samples analyzed are shown in tab. II. The total number of germs varies between $1.0x10^2$-$7.5x10^5$ CFU/g, the highest value being determined in a sample of *Calendula officinalis* ($CO2=7.5x10^5$ CFU/g). In accordance with the limits set by the *European Pharmacopoeia* for plant products to which hot water is added before use (10^7 CFU/g) (6), the values obtained were adequate.

TABLE II

Microbial contaminants values (CFU/g) present in the plant samples

Plant material samples	Total number of bacteria	Coliforms	Yeasts and molds	*E. coli*	*Coagulase-positive Staphylococcus*	*B. cereus*	*Salmonella*
MC1	$3.3x10^4$	**$2.6x10^2$**	$1.1x10^3$	0	2.1x10	0	0

HP4	$1.1x10^3$	0.4x10	8.0x10	0.4x10	0	0	0

Coliform bacteria, considered to be health indicators because of the fact that their presence indicates contamination with faecal bacteria, are not pathogenic bacteria, they are ubiquitous, but a large number of them may affect product quality and hence

consumer's health. The highest values were determined in some samples of *Matricaria chamomilla* (MC1=$2.6x10^2$ CFU/g) and *Tilia cordata* (TC1=$2.6x10^2$ CFU/g).

Yeasts and molds, widely distributed in the atmosphere, can provide information on the extent of contamination at all stages of production. In addition, under favorable conditions, certain fungi can synthesize highly toxic metabolites of the aflatoxin type (8, 9). The content of yeast and molds of the samples were adequate in relation to *European Pharmacopoeia* for plant products to which hot water is added before use (10^5 CFU/g) (6).

Escherichia coli is a commensal bacterium with a high capacity for adaptation and one of the main contaminants incriminated for food poisoning due to medicinal tea consumption (10). In the present study, *E. coli* was determined in 41.66% of the samples (0.4x10-$2.4x10^2$ CFU/g), predominantly in *Calendula officinalis* (75% of the samples). According to the *European Pharmacopoeia* requirements (6), only 8.33% of the samples had values ($2.4x10^2$ CFU/g) above the permissible limit (10^2 CFU/g or mL), that were harvested from the spontaneous flora and that belonged to the *Achillea millefolium* and *Calendula officinalis* species.

Coagulase-positive staphylococci are not common contaminants of medicinal teas. However, in 16.66% of the samples (*Achillea millefolium, Calendula officinalis, Matricaria chamomilla* and *Tilia cordata*) these pathogens were determined (0.2-2.4x10 CFU/g). The presence of these pathogenic bacteria in samples of packed medicinal teas indicates a contamination of human nature.

Bacillus cereus is a bacterium that multiplies by spores and it is involved in the occurrence of food poisoning caused by two distinct metabolites (enterotoxins), but maximum limits allowed for medicinal teas are still not set. Its presence was identified in 33.33% of the investigated samples (0.2-6.1x10 CFU/g), and it is found especially in *Achillea millefolium, Calendula officinalis* and *Matricaria chamomilla*. *Salmonella* spp. was absent in the all plant samples.

CONCLUSIONS

This study highlights some aspects regarding the quality of some medicinal plants commonly used in Romania as medicinal teas. Determinations made revealed the presence of specific pathogens (*Escherichia coli, Coagulase-positive Staphylococcus, Bacillus cereus*) in most of the samples investigated. The lowest prevalence of contamination was found in *Hypericum perforatum* samples. In order to ensure the quality and safety of medicinal plants consumption it is required to fully comply with the complete quality criteria so as to avoid microbial contamination in all stages of production. It is also necessary to identify the causes which favor the presence of the main etiological agents, as well as determining their role in generating disease in humans in order to prevent and decrease overall morbidity.

THE USE OF LIPIDS AS TASTE-MASKING AGENTS IN SOME PHARMACEUTICAL FORMS CONTAINING PARACETAMOL

Paracetamol is a fever reducer and a pain reliever used in many health conditions such as: fever, toothaches, headaches and even arthritis. However, the bitter taste of paracetamol represents a problem in pharmaceutical products for oral administration such as: tablets, chewable tablets, syrups or effervescent powders. In some patient caregories (children, elderly or patients with swallowing disorders) the use of these dosage forms is indispensable. Therefore, new methods for masking the unpleasant taste of some substances is needed. Lipids can be successfully used to coat the taste buds, covering the bitter taste of the drug and imparting a good mouth feel without delaying the release of the active substance. El-Refaie *et al.* investigated a new technique for paracetamol taste masking using lipid coating. The study aimed the investigation of some lipids (glyceryl palmitostearate, stearic acid and cetyl alcohol) potential to reduce the bitterness of paracetamol. Different ratios of paracetamol:lipid granulations were analyzed. The obtained granules were formulated as chewable tablets and sachets. Furthermore, the formulations were evaluated in terms of performance during storage. The characterization of the paracetamol:lipids formulations was performed using scaning electron microscopy and differential scanning calorimetry. In case of sachets, glyceryl palmitostearate showed a better masking of the taste, compared with the other two lipids, while in case of chewable tablets, two of the three analyzed formulations showed similar performance. Regarding the stability, the sachets proved to be stable for approximately 6 months, while for chewable tablets, only the formulations with cetyl alcohol presented taste masking changes during storage (El-Rafaie WM, El-Massik MA, Abdallah OY, Khalafallah NM. Formulation and evaluation of taste-masked paracetamol-lipid sachets and chewable tablets. *J Pharm Invest* 2014; 44(6): 431-442)

A SOFTWARE TOOL USED IN 3D EVALUATION OF THE ALVEOLAR BONE DEFECT IN BILATERAL CLEFT LIP AND PALATE PATIENTS (Abstract): Evaluation of the cleft size and the assessment of an estimative volume required for bone grafting provide useful information to the surgeon performing secondary alveolar bone grafting. **Aim:** To use a software tool to evaluate the estimative volume of the bone defect in the alveolar cleft area, based on cone beam computed tomography (CBCT) data. **Material and methods:** Three patients with bilateral cleft lip and palate (BCLP) were randomly selected in the order of referral to treatment at "Saint Mary" Emergency Hospital for Children. CBCT examinations were performed prior to secondary alveolar bone grafting procedure. The preoperative estimative volume (PEV) of the alveolar bone defect was evaluated by three observers with different areas of expertise (a dentomaxillofacial radiologist, a maxillofacial surgeon, and a Ph.D. radiology student), using Romexis 3.0.1 software program. The inter-observer fidelity was assessed using the Interclass Correlation Coefficient (ICC), with an optimal value of 0.837 for all observers. **Results:** The mean PEV for all BCLP patients was 1.84 ± 0.16 cm³. **Conclusions:** The results suggest that measuring the preoperative estimative volume of the alveolar bone defect in CLP patients using Romexis 3.0.1 software program, with CBCT scan data is beneficial. A proper protocol should be established, in order to provide useful information for the surgeon performing the secondary alveolar bone grafting. **Keywords:** BILATERAL CLEFT LIP AND PALATE, CONE BEAM COMPUTED TOMOGRAPHY, PREOPERATIVE, ALVEOLAR BONE DEFECT, SOFTWARE

Cleft lip and palate (CLP) consist in a heterogeneous group of pathologies that are among the most common malformations in the head and neck region and may determine various functional, aesthetic and social disorders (1). Previous European and US studies suggest that unilateral CLP is more frequent, and within CLP, only 20% are bilateral (2).

With the advancement of maxillofacial imaging, cone-beam computed tomography (CBCT) has become the procedure of choice when 3D imaging is necessary during CLP management, offering a lower dosage of radiation exposure compared to the classic CT (3-5), thus respecting the

ALARA (As Low As Reasonably Achievable) principle (6,7). CBCT examination brings essential information in the preoperative assessment, as well as in the outcome evaluation during different stages of the CLP surgical and orthodontic treatment, allowing accurate linear and three-dimensional measurements of the bone defect areas (8-10).

Evaluation of the cleft size and the assessment of an estimative volume required for bone grafting provide useful information to the surgeon performing secondary alveolar bone grafting, influencing the choice of an optimal donor site. The aim of this study was to use a software tool to calculate the estimative volume of the bone defect in the alveolar cleft area, based on the CBCT data collected from three patients presenting bilateral cleft lip and palate (BCLP), prior to secondary alveolar bone grafting.

MATERIAL AND METHODS

From all the CLP patients presented to pursue surgical treatment at "Saint Mary" Emergency Hospital for Children, between 1 January 2014 and 30 June 2014, three BCLP patients were randomly selected in the order of referral to treatment.

Neither of the selected patients had undergone secondary alveolar bone grafting, or followed any orthodontic treatment. Patients presenting other congenital malformations or syndromes were excluded from the study. An informed consent for research, approved by the Ethics Committee, was obtained from all patients' parents/tutors.

TABLE I

Patients' characteristics and protocol used during CBCT data collection

Patient	Cleft type	Age	Sex	Voxel (m)	DAP* (mGy x cm²)	Tube current (mA)	Tube voltage (kV)	Scan Time (s)
C.A-E.	BCLP**	14	F	400	2490	10.0	90	27
C.I.	BCLP**	9	M	400	1992	8.0	90	27.5
G.M.M.	BCLP**	11	M	400	2242	9.0	90	28

* Dose-Area-Product

** Bilateral Cleft Lip and Palate

CBCT examinations were performed prior to secondary alveolar bone grafting procedure, in a private radiology clinic. A Planmeca Promax 3D MID (*Planmeca Oy, Helsinki, Finland*) unit was used to collect CBCT data, with the patient in upright sitting position, Frankfort horizontal plane being parallel to the floor. Technical parameters for obtaining CBCT data were selected based on the patient's age and body structure (tab. I).

The scans were reconstructed using three - dimensional imaging software Romexis 3.0.1 (*Planmeca OY, Helsinki, Finland*) (fig.1). In order to achieve coronal, sagittal and axial views, sections were established with a thickness of 1 mm and at a distance of 1 mm.

All CBCT scans were screened independently by three observers with different

areas of expertise (a dentomaxillofacial radiologist, a maxillofacial surgeon, and a Ph.D. radiology student). Prior to the assessment of the alveolar bone defect volume, all observers agreed on defining the following limits of the region of interest: the superior limit was set to be the nasal floor plane, defined as the plane parallel to the Frankfort horizontal plane that passed through the anterior and posterior nasal spine; the inferior limit was considered to be the inferior margin of the alveolar bone adjacent to the cleft; the lateral boundaries were represented by the limits of the alveolar bone surrounding the teeth adjacent to the cleft (fig. 2).

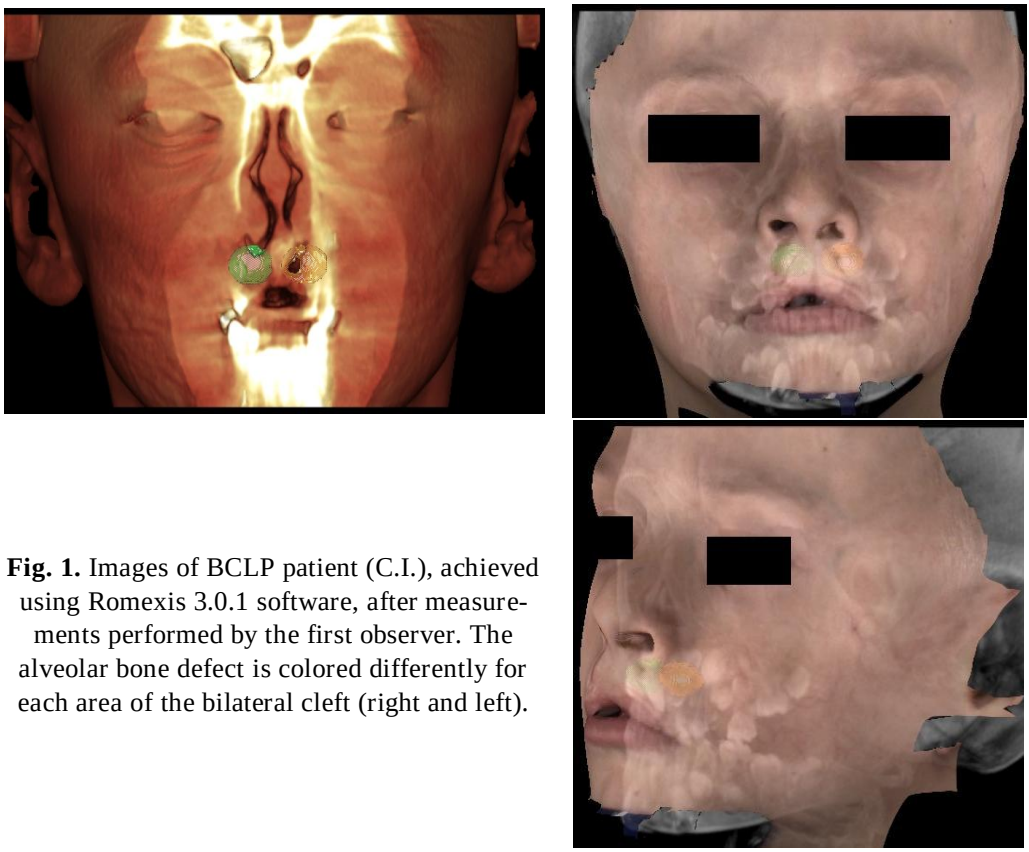

Fig. 1. Images of BCLP patient (C.I.), achieved using Romexis 3.0.1 software, after measurements performed by the first observer. The alveolar bone defect is colored differently for each area of the bilateral cleft (right and left).

The alveolar bone defect was traced by selecting Volume rendering option in the Tools panel, then by using the elliptical cursor to establish the limits of the cleft aria, in both sides separately (fig. 2). The established limits were evaluated by every observer separately, in all CBCT sections in coronal, sagittal and axial planes.

Statistical analysis was performed using SPSS version 20.0 (*SPSS Inc, Chicago, IL*). The Intraclass Correlation Coefficient (ICC) was used to evaluate the inter-observer reliability in the assessment of the alveolar bone defect volume using Romexis 3.0.1 software program. The results showed no significant difference between the inter-

observer measurements, with a ICC value of 0.837 for all three observers. The ICC value for average measures was calculated with a 95% confidence interval. The resulting value indicates an optimal inter-observer reliability.

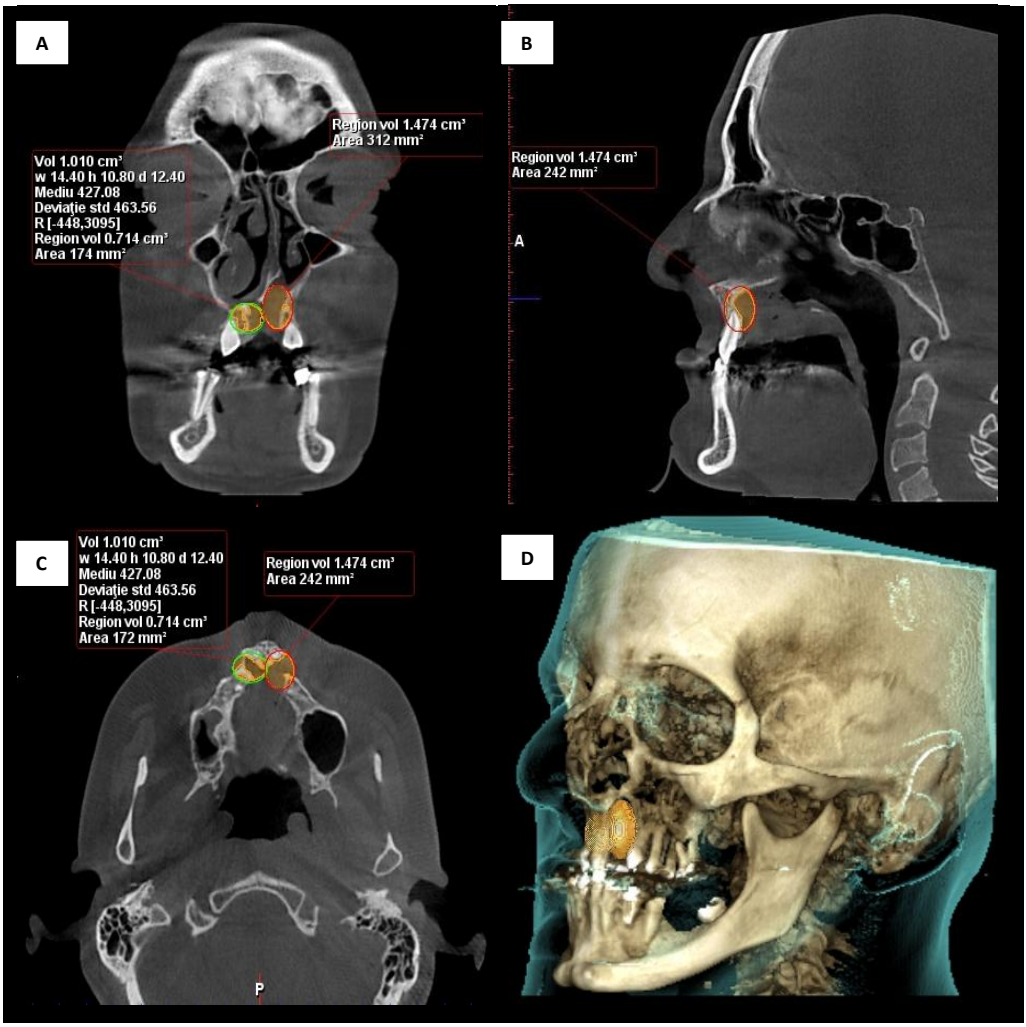

Fig. 2. Assessment of alveolar bone defect in BCLP patient (C.A-E.); A – coronal view; B – sagittal view; C – axial view; D – three-dimensional view, soft and hard tissues.

RESULTS

The results of the measurements performed by all three observers are presented in Table II. The mean value for the right and the left area of each cleft region resulted from the values obtained by all the observers. The combined average volume for both sides of the bilateral clefts resulted in the overall preoperative estimated volume (PEV) for each BCLP patient (tab. II). The mean PEV for all BCLP patients was 1.84 ± 0.16 cm³.

TABLE II

Estimative bone defect volume in the alveolar cleft area, calculated by all observers

*O1: Observer 1 (maxillofacial surgeon); **O2: Observer 2 (dentomaxillofacial radiologist); ***O3: Observer 3 (Ph.D. radiology student); ****PEV: Preoperative estimative volume

DISCUSSION

The preoperative volumetric assessment of the alveolar bone defect provides useful information for the secondary alveolar bone grafting, which is considered the gold standard in the surgical reconstruction of the cleft region (4, 10-12). The accurate evaluation of the alveolar bone defect helps determining the quantity of bone necessary to the bone grafting procedure, thus influencing the choice of the optimal donor site and avoiding inadequate bone harvesting (11, 12).

Previous studies have reported a significant correlation between the size of the alveolar bone defect in the cleft area and the success of the secondary alveolar bone grafting procedure (13-15).

Most studies evaluating PEV of the alveolar bone defect have been conducted on unilateral CLP (UCLP) patients. A possible explanation may be the lower prevalence of BCLP compared to UCLP (2).

The PEV values reported by previous studies conducted among BCLP patients vary widely. Choi et al. reported findings slightly lower than ours ($1.4\pm0.4cm^3$) (16). Oberoi et al. reported even lower values: 0.82cm3 (4). Shirota et al. study included only two BCLP patients and declared higher findings compared to ours: $3cm^3$ and, respectively, $3.8cm^3$ (14).

There may be various explanations for the differences found among these studies. Different software programs were used to assess the PEV of the alveolar bone defect in CLP patients. Meanwhile, the absence of a specialized multidisciplinary center for the treatment of CLP patients in Romania, along with the unavailability of an adequate protocol for the CLP management, leads to an incomplete CLP management for many patients. All the patients involved in this study had not undergone orthodontic treatment, which must begin prior to secondary alveolar bone grafting (2). The absence of maxillary expansion may explain our findings being higher than those reported by other studies.

CONCLUSIONS

The results suggest that measuring the preoperative estimative volume of the alveolar bone defect in CLP patients using

Romexis 3.0.1 software program, with CBCT scan data is beneficial. A proper protocol should be established, in order to provide useful information for the surgeon performing the secondary alveolar bone grafting.

IN VITRO SCREENING OF *CRATAEGUS SUCCULENTA* EXTRACTS FOR FREE RADICAL SCAVENGING AND 15-LIPOXYGENASE INHIBITORY ACTIVITIES (Abstract): *Crataegus succulenta* Schrad. ex Link is widely spread in North America. A literature survey revealed no studies on the chemical composition and biological effects of this species. **Aim**: The aim of the present study was to investigate the phenolic content, free radical scavenging and 15-lipoxygenase inhibitory effects of *Crataegus succulenta* leaf and flower extracts. **Material and methods**: Total phenolic, flavonoid and proanthocyanidin contents were quantified by spectrophotometric methods. Both extracts were evaluated for their ability to scavenge DPPH, superoxide anion and hydroxyl radicals and to inhibit 15-lipoxygenase activity. **Results**: There were noticed no striking differences in the total phenolic, flavonoid and proanthocyanidin contents between leaf and flower extracts. Both extracts showed similar 15-lipoxygenase inhibitory effects. Flower extract scavenged more effectively DPPH and superoxide radicals while leave extract was more active against hydroxyl radical. In superoxide anion radical scavenging assay, both extracts were more active than (+)-catechin. In hydroxyl radical scavenging and 15-lipoxygenase inhibition assays, the extracts were only 4-5 times less active than (+)-catechin. **Conclusions**: The high antioxidant potential of *Crataegus succulenta* extracts suggest a possible use as ingredients in functional foods for the prevention of oxidative stress-related diseases.
Keywords: *CRATAEGUS SUCCULENTA*, SUPEROXIDE ANION RADICAL, HYDROXYL RADICAL, 15-LIPOXYGENASE

The genus *Crataegus* (Rosaceae) consists of approximately 300 species widely spread in the northern hemisphere. Many of these species have been used in folk medicine in the treatment of gastrointestinal, urinary and cardiovascular disorders. Flavonoids (vitexin, orientin and their derivatives, hyperoside, rutin) and oligomeric procyanidins are the main phytochemicals that have been identified in the leaves, flowers and berries of many *Crataegus* species. *Crataegus* extracts have beneficial effects on the cardiovascular system exhibiting antioxidant, antiatherosclerotic, hypo-

tensive, positive inotropic, coronary dilatation and antiarrhythmic effects (1, 2).

Crataegus succulenta Schrad. ex Link (syn. *Crataegus macracantha* Loudon, fleshy hawthorn, succulent hawthorn) is widely spread in North America (3). The species has not been studied regarding its chemical composition and possible biological effects. In this respect, the aim of the present work was to investigate the phenolic content, free radical scavenging and 15-lipoxygenase inhibitory effects of leaf and flower extracts.

MATERIAL AND METHODS

Chemicals.

Tris(hydroxymethyl)aminomethane (Tris) and hydrochloric acid were purchased from Merck (Darmstadt, Germany). Ethylenediaminetetraacetic acid (EDTA), pyrogallol, Folin-Ciocalteu's phenol reagent, linoleic acid, lipoxydase from soybean were from Fluka (Steinheim, Germany). (+)-Catechin hydrate, gallic acid, sodium carbonate, 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical, iron (II) sulfate heptahydrate, hydrogen peroxide, sodium salicylate were from Sigma-Aldrich (Steinheim, Germany). Ammonium iron (III) sulfate dodecahydrate and sodium nitrite were obtained from Riedel-de Haën (Seelze, Germany). All other solvents and reagents were of analytical grade.

Plant material. Leaves and flowers of *Crataegus succulenta* Schrad. ex Link were collected in the Botanical Garden "Anastasie Fatu", Iasi in May 2010. The identity of the plant material was confirmed by taxonomists from Botanical Garden "Anastasie Fatu". Leaves and flowers were dried in dark at room temperature. Voucher specimens have been deposited in the Discipline of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy "Grigore T. Popa"-Iasi.

Extraction. Dried and powdered leaves and flowers (50 g each) were extracted with 500 mL of 70% aqueous methanol by stirring for 6 h at room temperature. The extraction was repeated twice. The combined extracts were concentrated under reduced pressure at 40°C and then freeze-dried.

Total phenolic content. Total phenolic content was quantified by Folin-Ciocalteu method as previously described (4). Electron-donating compounds such as phenols react with phosphomolybdic/ phosphotungstic acid complexes in Folin-Ciocalteu reagent and form a blue complex. The results were expressed as g gallic acid equivalents (GAE)/100 g extract using the following equation based on the calibration curve: $y=0.1165\times+0.0269$, $R^2=0.9987$.

Flavonoid content. Flavonoids were quantified by a spectrophotometric method based on their ability to generate pink coloured products in the presence of sodium nitrite and aluminium chloride, in alkaline solution (5). The results were expressed as g catechin equivalents/100 g extract using the following equation based on the calibration curve: $y=0.0759\times - 0.0038$, $R^2=0.9984$.

Proanthocyanidin content. The assay, described by Porter *et al*., is based on the conversion of proanthocyanidins to anthocyanidins in *n*-butanol-HCl and in the presence of ferric salts (6). The results were expressed as cyanidin equivalents (g cyanidin/100 g extract) using the molar extinction coefficient and molecular mass of cyanidin (ε=17,360 $L\cdot mol^{-1}\cdot cm^{-1}$ and M=287.24, respectively) (7).

DPPH radical scavenging assay. Antioxidants reduce DPPH radical (purple) to diphenylpicrylhydrazine DPPH-H (yellow) leading to a decrease in absorbance at 517

nm (4). (+)-Catechin hydrate was used as positive control. DPPH scavenging activity (%) was calculated as:

$100 \times (A_{start}\text{-}A_{end}/A_{start})$ where A_{start} and A_{end} are the absorbances of DPPH radical solution before and 5 min after adding the samples, respectively.

Superoxide anion radical scavenging assay. Superoxide anion radical, generated by the auto-oxidation of pyrogallol, oxidizes the latter to quinones that are quantified spectrophotometrically (8). (+)-Catechin hydrate was used as positive control. Superoxide anion radical scavenging activity (%) was calculated as follows: $100 \times (slope_{control}\text{-}slope_{sample}/slope_{control})$ where $slope_{control}$ and $slope_{sample}$ are the slopes of the plots of absorbance *vs.* time for control and samples, respectively.

Hydroxyl radical scavenging assay. The assay is based on the ability of hydroxyl radical, generated by Fenton reaction, to produce a violet product in the presence of sodium salicylate and ferric ions (9). (+)-Catechin hydrate was the positive control. Hydroxyl radical scavenging activity (%) was calculated as: $100 \times (A_{control}\text{-}A_{sample}/A_{control})$ where $A_{control}$ is the absorbance of the control and A_{sample} is the absorbance in the presence of extracts/(+)-catechin.

15-Lipoxygenase inhibition assay. In the presence of 15-lipoxygenase, linoleic acid is oxidized to conjugated dienes which strongly absorb at 234 nm. The assay was performed as described by Wangensteen *et al*. with minor changes (4). (+)-Catechin hydrate was used as positive control. 15-Lipoxygenase inhibition (%) was determined on the basis of the absorbance of the control and samples after 30 and 90 s reaction time as follows:

$$100 \times [(A_{control,90}\text{-}A_{control,30})\text{-}(A_{sample,90}\text{-}A_{sample,30})/(A_{control,90}\text{-}A_{control,30})].$$

Statistical analysis. All experiments were carried out in triplicate. The results were expressed as means±standard deviations. The EC_{50} values were calculated by linear interpolation between values above and below 50% activity.

RESULTS

Extraction. The extraction afforded 13.3 g of leave extract (S-l, yield: 26.6%) and 13.1 g of flower extract (S-f, yield: 26.2%).

Total phenolic, flavonoid and proanthocyanidin contents. S-l and S-f contained similar amounts of total phenolics, flavonoids and proanthocyanidins (tab. I).

TABLE I
Total phenolic, flavonoid and proanthocyanidin contents in *Crataegus succulenta* extracts

Extract	Total phenolic content (%)	Flavonoid content (%)	Proanthocyanidin content (%)
S-l	15.33 ± 0.40	5.25 ± 0.42	3.5 ± 0.0
S-f	16.15 ± 0.23	5.16 ± 0.30	3.65 ± 0.17

S-l – leave extract; S-f – flower extract

DPPH radical scavenging assay. DPPH radical scavenging effects of S-l and S-f were found to increase in a dose-dependent manner from 11.96±0.14 and 13.31±0.24%, respectively at 10.41 µg/mL to 89.08±0.31 and 92.62±0.04%, respectively at 166.66 µg/mL. At the same concentrations, (+)-catechin exhibited scavenging effects of

84.49±0.50 and 95.37±0.47%, respectively (fig. 1). An additional dilution (5.20 µg/mL) was tested in order to determine the EC_{50} value of (+)-catechin; at this dilution, a scavenging activity of 46.98±0.11% was registered. According to the EC_{50} values, S-f (46.7±0.2 µg/mL) was more active than S-l (52.0±0.5 µg/mL). The EC_{50} value of (+)-catechin was found to be 5.5±0.0 µg/mL suggesting a higher DPPH radical scavenging ability than *Crataegus succulenta* extracts (tab. II).

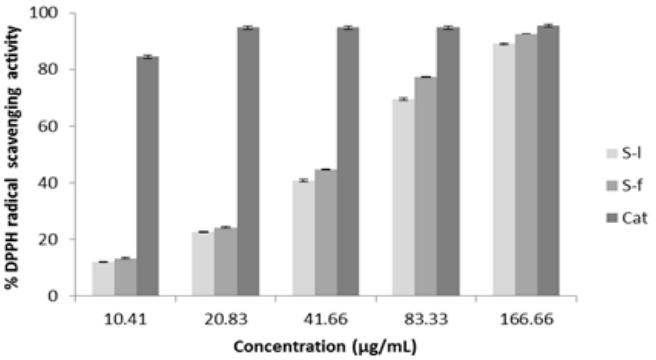

Fig. 1. DPPH radical scavenging activity of *Crataegus succulenta* extracts (S-l – leave extract; S-f – flower extract; Cat – (+)-catechin)

Superoxide anion radical scavenging assay. Superoxide anion radical scavenging activity was dose dependent for both extracts. In the concentration range of 0.65-0.87 mg/mL, (+)-catechin exhibited only 20.15-24.02% scavenging activity (fig. 2). Therefore, in order to calculate the EC_{50} value of (+)-catechin, higher concentrations (1.61, 2.26 and 2.58 mg/mL) were tested. At these concentrations, (+)-catechin scavenged superoxide anion radical by 40.15±1.31, 48.83±0.00 and 52.70±1.33%, respectively. Within this assay, both extracts were more active than (+)-catechin; the EC_{50} value of S-f (0.65±0.01 mg/mL) was lower than that of S-l (0.73±0.00 mg/mL) suggesting stronger scavenging properties for the former (tab. II).

Hydroxyl radical scavenging assay. In this assay, both extracts showed concentration-dependent scavenging effects but they were less active than (+)-catechin. At 1.87 mg/mL, the scavenging effects of S-l, S-f and (+)-catechin were found to be 56.57±0.79, 66.76±0.80 and 90.01±1.81%, respectively (fig. 3). With regard to the EC_{50} values, S-l (1.26±0.05 mg/mL) and S-f (1.6±0.0 mg/mL) were only 4-5 times less active than (+)-catechin (0.3±0.0 mg/mL) (tab. II).

15-Lipoxygenase inhibition assay. *Crataegus succulenta* extracts inhibited 15-lipoxygenase in a concentration-dependent manner with similar EC_{50} values (S-l: 154.6±0.6 µg/mL, S-f: 154.86±0.35 µg/mL) (fig. 4, tab. II). In the range of tested concentrations (100-166.66 µg/mL), (+)-catechin exhibited high activity (95.22±0.76-99.99±0.01%);therefore, lower concentrations (20.83, 41.66 and 83.33 µg/mL) were tested in order to determine its EC_{50} value; at these concentrations, catechin exhibited 31.65±0.53, 67.05±0.16 and 87.07±0.26% scavenging activity, respectively. (+)-Catechin inhibited 15-

lipoxygenase activity with an EC_{50} value of 29.2±0.2 µg/mL. With regard to the EC_{50} values, both extracts were 5 times less active than (+)-catechin (tab. II).

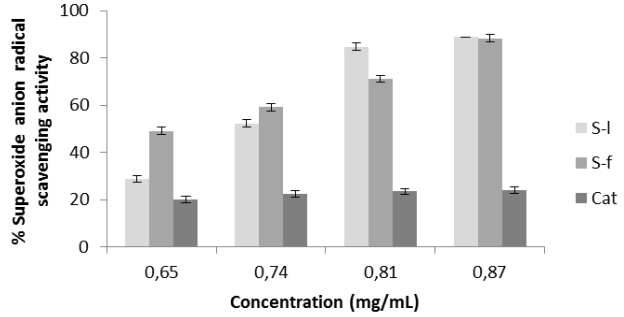

Fig. 2. Superoxide anion radical scavenging activity of *Crataegus succulenta* extracts (S-l – leave extract; S-f – flower extract; Cat – (+)-catechin)

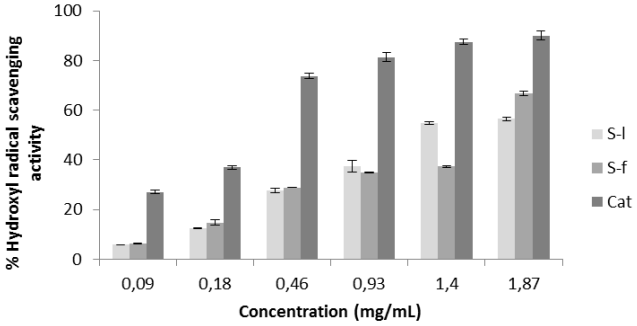

Fig. 3. Hydroxyl radical scavenging activity of *Crataegus succulenta* extracts (S-l – leave extract; S-f – flower extract; Cat – (+)-catechin)

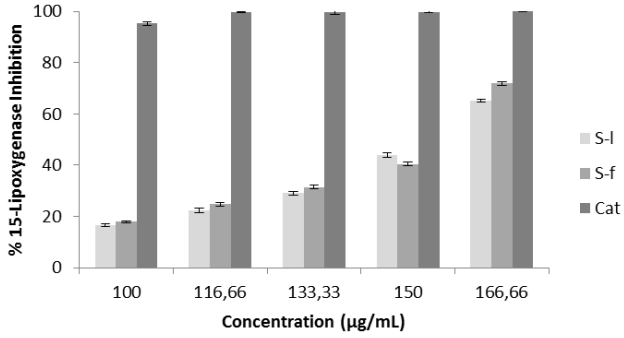

Fig. 4. 15-Lipoxygenase inhibitory activity of *Crataegus succulenta* extracts (S-l – leave extract; S-f – flower extract; Cat – (+)-catechin)

DISCUSSION

This *in vitro* screening compared the free radical scavenging and 15-lipoxygenase inhibitory effects of *Crataegus succulenta* extracts with those of (+)-catechin. Due to the *o*-dihydroxy moiety, catechin is one of the most potent free radical scavengers (10, 11). In addition, catechin has been reported to be an efficient inhibitor of 15-lipoxygenase (12). It is worthy to note that, in superoxide anion radical scavenging assay, both extracts were more active than (+)-catechin. In hydroxyl radical scavenging and 15-lipoxygenase inhibition assays, the extracts were only 4-5 times less active than (+)-catechin. In light of these data, it is obvious that *Crataegus succulenta* extracts are efficient free radical scavengers and 15-lipoxygenase inhibitors. These effects suggest potential therapeutic applications for *Crataegus succulenta* extracts. Reactive oxygen species such as superoxide anion and hydroxyl radicals are involved in the development of many chronic diseases (cardiovascular, neurodegenerative and malignant diseases) (5). 15-Lipoxygenase is a prooxidant enzyme; it catalyzes the oxidation of low-density lipoproteins (LDL) being a source of free radicals responsible for non-enzymatic oxidative processes. 15-Lipoxygenase is involved in the development of atherosclerosis, prostate cancer, diabetes, Alzheimer's and Parkinson's diseases (13).

This study revealed no striking differences in total phenolic, flavonoid and proanthocyanidin contents between *Crataegus succulenta* extracts. According to the EC_{50} values, both extracts showed similar 15-lipoxygenase inhibitory activities but different free radical scavenging effects. S-f scavenged more effectively DPPH and superoxide radicals while S-l was more active against hydroxyl radical. A lack of concordance between the antioxidant effects of *Crataegus succulenta* extracts is noticeable. Such a lack of concordance between the antioxidant properties evaluated by different assays has already been mentioned in literature and might have two possible explanations: first, the different chemical profile of the antioxidant constituents in plant extracts that significantly affects the antioxidant activity and second, the complexity of the mechanisms involved in antioxidant activity (14).

CONCLUSIONS

The results of this study suggest the possibility that extracts from the leaves and

flowers of *Crataegus succulenta* could be used as ingredients in functional foods for the prevention of oxidative stress-related diseases. Further research is required to investigate the *in vivo* efficacy and safety of the extracts.

DIFFERENTIAL EQUATIONS WITH APPLICATIONS IN CANCER DISEASES (Abstract): Mathematical modeling is a process by which a real world problem is described by a mathematical formulation. The cancer modeling is a highly challenging problem at the frontier of applied mathematics. A variety of modeling strategies have been developed, each focusing on one or more aspects of cancer. **Material and methods:** The vast majority of mathematical models in cancer diseases biology are formulated in terms of differential equations. We propose an original mathematical model with small parameter for the interactions between these two cancer cell sub-populations and the mathematical model of a vascular tumor. We work on the assumption that, the quiescent cells' nutrient consumption is long .One the equations system includes small parameter ε . The smallness of ε is relative to the size of the solution domain. **Results**: MATLAB simulations obtained for transition rate from the quiescent cells' nutrient consumption is long, we show a similar asymptotic behavior for two solutions of the perturbed problem .In this system, the small parameter is an asymptotic variable, different from the independent variable. The graphical output for a mathematical model of a vascular tumor shows the differences in the evolution of the tumor populations of proliferating, quiescent and necrotic cells. The nutrient concentration decreases sharply through the viable rim and tends to a constant level in the core due to the nearly complete necrosis in this region. **Conclusions**: Many mathematical models can be quantitatively characterized by ordinary differential equations or partial differential equations. The use of MATLAB in this article illustrates the important role of informatics in research in mathematical modeling. The study of avascular tumor growth cells is an exciting and important topic in cancer research and will profit considerably from theoretical input. Interpret these results to be a permanent collaboration between math's and medical oncologists. **Keywords**: STEM CELLS, VASCULAR TUMOR, DIFFERENTIAL EQUATIONS, NUMERICAL MODELING.

Cancer is one of the main causes of morbidity and mortality in the world. Mathematical modeling plays an important role especially in cancer stem cells and tumor growth. The mathematical exploration of cancer was initiated in the 1950s with a study of the age dependent incidence curves of human cancers. Mathematical modeling and computational approaches have become more accepted by clinicians as contributing to new understandings of complicated cancer mechanisms and tissue physiology. Basic models represented in this article by two or three equations allowing a qualitative examination. In recent years, cancer stem cells have become the subject of theoretical investigations as well, and studies were performed to elucidate the

biology and dynamics of colorectal cancer stem cells, breast cancer stem cells, hematologic malignancies, and the role of stem cells in the evolution of drug resistance. Proliferating cells can divide with constant rate or lose their division ability and therefore transit to the resting phase. Resting cells can either return to the proliferating state or die with constant rate. His interactions between these two cancer cell subpopulations are described in this article by the original singularly perturbed system of ordinary differential equations. It is additionally assumed that the transition from the quiescent to the proliferating state depends on the number of proliferating cells only. The majority of mathematical models of solid tumor growth seem to have appeared in the literature since 1990 .In recent years, applied mathematicians and oncologists have collaborated to develop models and simulations that characterize a vascular tumor (1).Tumors appear when cells lack of growth control. Uncontrolled proliferation can be the result of different alterations of normal cells properties. To proliferate, cells need nutrients and oxygen coming from existing vascular vessels surrounding the tissue where the tumor grows.

MATERIAL AND METHODS

We analyze an original singularly perturbed system of ordinary differential equations for the model with form:

$$(P_\varepsilon)\begin{cases}\varepsilon\dfrac{dx}{dt}=\varepsilon a_1 x - x - a_2 y\\ \varepsilon\dfrac{dy}{dt}=x + a_2 y - \varepsilon a_3 y\end{cases}$$

where $x(t)$ and quiescent cancer cell $y(t)$ populations, based on experimental data. Proliferating cells can divide with constant rate a_1 or lose their division ability and therefore transit to the resting phase. Resting cells can either return to the proliferating state or die with constant rate a_3, and a_2 describe the proliferating cells' nutrient consumption (2). The interactions between these two cancer cell subpopulations are described by the following system of ordinary differential equations with small parameter. It is additionally assumed that the transition from the quiescent to the proliferating state depends on the number of proliferating cells only. We work on the assumption that $\frac{1}{\varepsilon}$, the quiescent cells' nutrient consumption is long, where ε is the small parameter. The use of a small parameter here is simply for definiteness. Should mention this model system differential equations with small parameter are experimental and must be validated in future theoretical results. Mathematical modeling of a vascular tumor can be seen as the first step in building models for tumors in later stages. There are several different stages in the growth of a tumor before it becomes so large that it causes the patient to die or reduces permanently their quality of life. The factors that trigger these mutations are unknown, but are thought to include both environmental and hereditary effects. The most significant turning point in cancer, however, is the establishment of metastasis. The metastatic spread of tumor cells is the predominant cause of cancer deaths. Metastasis signifies that a tumor is malignant and this is in fact what makes cancer so lethal. Nonlinear differential equations modeling has been performed to study the effects of morphology instabilities on both avascular and vascular solid tumor growth (3) .This mathematical mod-

els (is based on a set of partial differential equations) provide a powerful analysis tool to dissect the biological mechanisms and the role of tumor growth in angiogenesis and the consequences of its inhibition.

$$(2)\begin{cases}\dfrac{da}{dt}=\dfrac{\partial}{\partial x}\left(\dfrac{a}{a+b}\dfrac{\partial(a+b)}{\partial x}\right)+0.4e^{0.4u}a(1-a-b-c)-\dfrac{(1-e^{-\frac{u}{2}})}{2}a\\ \dfrac{db}{dt}=\dfrac{\partial}{\partial x}\left(\dfrac{b}{a+b}\dfrac{\partial(a+b)}{\partial x}\right)+\dfrac{(1-e^{-\frac{u}{2}})}{2}a-\dfrac{(1-e^{-\frac{u}{2}})}{4}b\\ \dfrac{dc}{dt}=\dfrac{(1-e^{-\frac{u}{2}})}{4}b\end{cases}$$

Where are denoted by:

$a(x,t),b(x,t),c(x,t),u(x,t)$ the cell densities for the proliferating, quiescent, necrotic cells and concentration of some nutrients. The nonlinearity of this model is their most important property: it reflects mathematically the openness of biological systems and their state beyond thermodynamic equilibrium.

RESULTS

We investigate, using numerical computation, the behavior of the models in various small parameter regimes. In Figure 1-5 we present numerical solutions of the differential equations systems (P_ε), (2) for different parameter values .The choice of a small parameter is connected with the order of the solution and the asymptotic sequence which describes the behavior of the solution as $\varepsilon \to 0$. The overall procedure for work is: develop an appropriate scaling for the equations, identify the small parameter, writing regular series, writing boundary function series. The simulation of a single set of equation can be performed on a single workstation because the numerical integration of a system (P_ε) not very time consuming. The parameter values have highs impact on the accuracy of the model in representing real biological systems but these values are difficult to estimate experimentally (4). Using the program MATLAB, I did various simulations for different values of biological parameters presented in the models studied. MATLAB simulations obtained for transition rate from the quiescent cells' nutrient consumption is long, we show a similar asymptotic behavior for two solutions of the perturbed problem (5) .The choice of a small parameter is connected with the order of the solution and the asymptotic sequence which describes the behavior of the solution as $\varepsilon \to 0$.

The growth dynamics for vascular tumors are of particular interest because vascular tumors, having their own blood supply, have nearly limitless provisions of nutrient. The graphical output in this article shows the differences in the evolution of the tumor populations of proliferating, quiescent and necrotic cells. Graphical observation is that cancer cells need a high nutrient environment to proliferate, tumor grow is influenced by cell movements as well as other cell growth factors. Necrotic

cells are dead while proliferating and quiescent cells can move. The nutrient concentration decreases sharply through the viable rim and tends to a constant level in the core due to the nearly complete necrosis in this region (6). Necrotic cells can be the result of different alterations of normal cells properties.

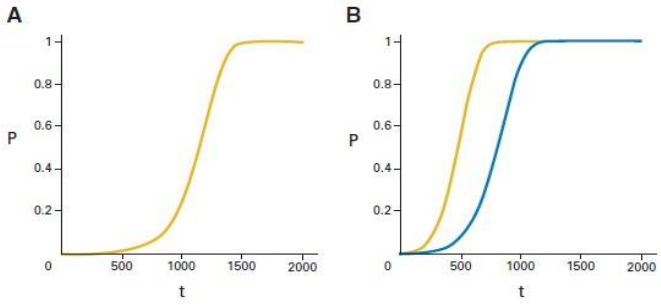

Fig. 1. (A) The curve is the same for patients receiving imagine therapy and for untreated patients, because imagines cannot deplete cancer stem cells. The higher growth rate for the normal cells increases the region of acceptable drug regimens. (B) The right curve shows the probability of blast crisis when the patient is treated, and the left curve shows the probability of blast crisis when there is no treatment.

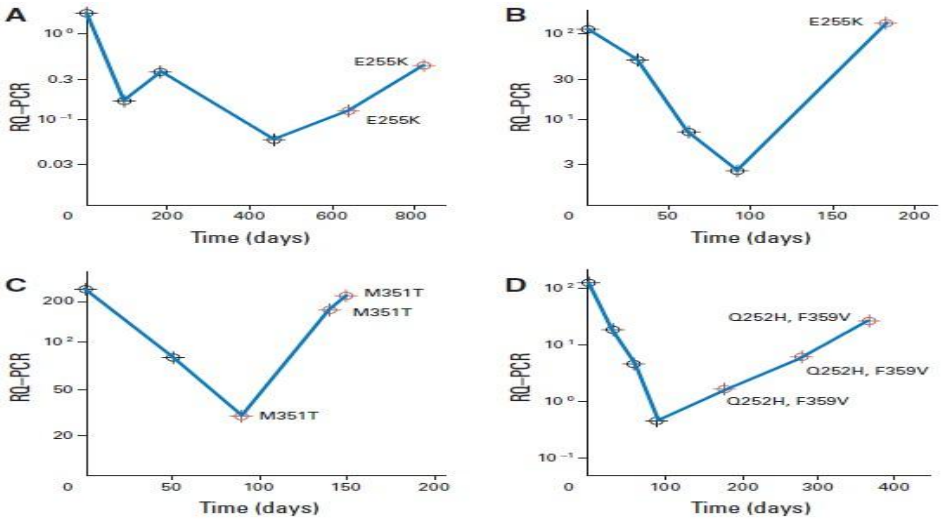

Fig. 2. A numerical simulation shows the dynamics resistances mutations lead to relapse of cancer stem cells for different values of parameter a_1, a_2, a_3. Parameter estimation adjusts this model to reproduce the experimental results in the best possible way for a set of experimental data. For these parameters, solutions can change on a time scale that is very short compared to the interval of integration, but the solutions of interest changes on a much longer time scale.

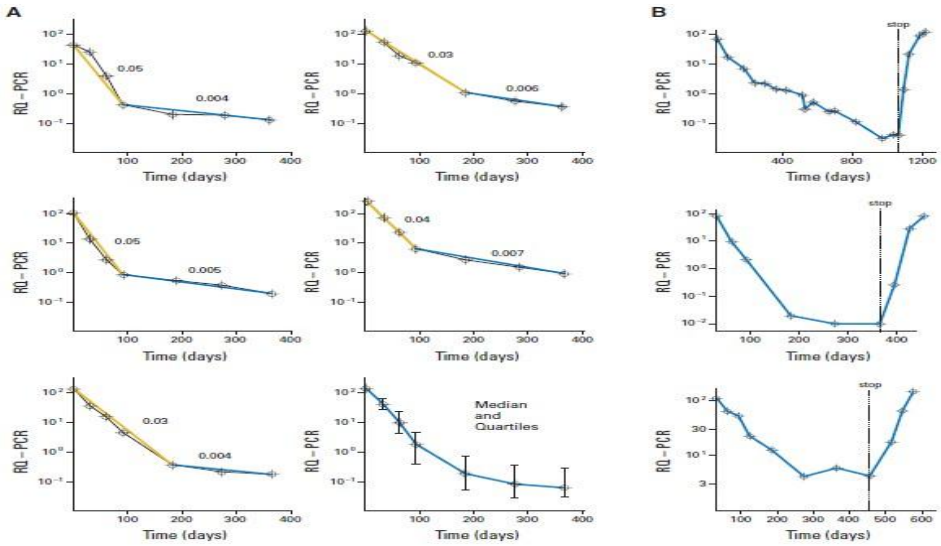

Fig. 3. (A) Drugs lead to a biphasic decline of cancer cells. The sixth figure shows the median with quartiles taken over all patients who do not evolve resistance mutations. (B) Discontinuation of drugs therapy leads to a rapid increase of cancer cells to levels at or beyond pretreatment baseline. Therefore, cancer stem cells are not depleted by drugs during this time period.

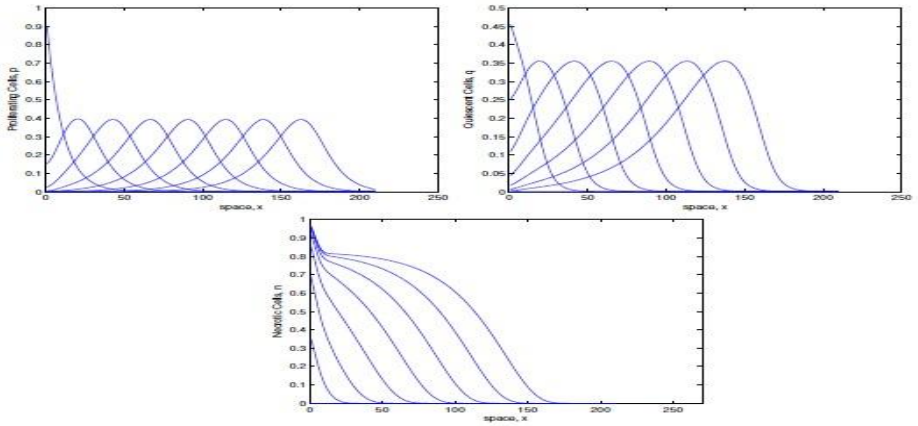

Fig. 4. The numerical simulations shows the cells densities of proliferating, quiescent, and necrotic cells plotted as a function of space of time, and curves moves from left to right as time increases. The surviving quiescent cells can thus proliferate afterwards because of the renewed nutrient supply, and the tumor may then recover. Necrotic cells formation is also a very poorly-understood aspect of tumor development.

Generally the estimation of the kinetic parameters is performed by fitting the experimental by computing a number of ordinary differential equations systems with different parameters and verifying the best solution.

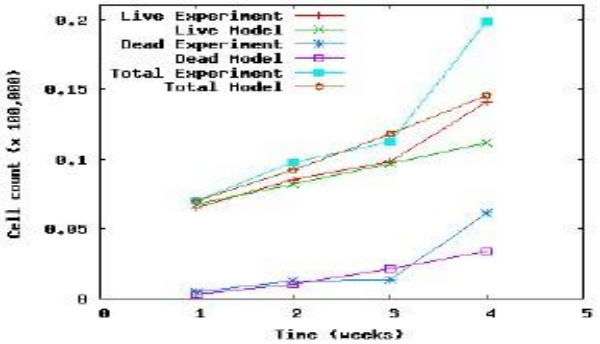

Fig. 5. Cell counts between calibrated model and experimental data. Calibration model should be included in probabilistic sensitivity analyses .The parameter values have highs impact on the accuracy of this model in representing real biological systems but these values are difficult to estimate experimentally. Adjustments may need to be made to account for temporal shifts in data.

CONCLUSIONS

Modeling cancer has become one of the active areas within the mathematical, oncologists and theoretical biology communities. This model is essentially based on differential equations and they can describe abundances kinetics and binding affinities of pathway components and their interactions. Validating a model is essentially examining whether it is good enough in relation to its intended purpose. A valid model is one that has successfully passed through the validation process. Proper validation of the above models will require input from statisticians. In this article, the models above ignore stochastic effects. The complexity of this biological process is revealed every time a mathematical simulation of the processes is carried out. The models are solved numerically using the software MATLAB. The use of MATLAB in this article illustrates the important role of informatics in research in mathematical modeling. Should mention these differential equations systems with small parameter are experimental and must be validated in future theoretical results. The lacunae in our understanding of tumors growth and invasion necessitate a sustained input by mathematicians into current and future investigations. Future work will include thereby formulating a more comprehensive model for vascular tumors growth.

REMOTE RESPIRATION MONITORING SYSTEM FOR SLEEP APNEA DETECTION (Abstract): Sleep is a dynamic physiological process, its primary function being the restoration of the central nervous system. Because sleep disorders affect a significant part of the population the dynamic long term monitoring of human respiration plays a very important role in diagnosis and treatment. **Material and methods:** We describe a remote monitoring system designed for in-hospital or at-home detection with a high degree of accuracy of sleep-related disorders in patients experiencing episodes of obstructive sleep apnea. Patient's respiratory rate is continuously measured by using wireless devices and then transfered to a central monitoring station via a wireless sensor network. The central monitoring station runs a respiration monitoring application that receives the patient's respiratory rate from the network and activates an alert upon detection of a sleep apnea episode. **Results:** A user-friendly graphical user interface was designed for the respiration monitoring application that displays patient's respiratory rates and sleep apnea alerts. A prototype of the system has been developed, implemented and tested. **Conclusions:** The described system allows persons with respiratory diseases or elderly to be monitored at their homes, as an alternative to medical supervision in hospitals. **Keywords:** APNEA DETECTION, REMOTE MONITORING, WIRELESS SENSOR NETWORKS.

Sleep is a naturally recurring state of rest for the mind and body, a third of life being spent. During sleep the whole central nervous system is restored. Therefore, good sleep is an important component of a healthy lifestyle. However, sleep disorders affect a significant part of the population. According to the American Academy of Sleep Medicine approximately 20% of the population in modern societies suffers from sleep disorders. For instance, in Europe the prevalence of obstructive sleep apnea is estimated at 2% of women and 4% of men, having a direct impact on their quality of life (1).

The remote sleep monitoring devices, integrated into a system, allow patients to be monitored from a distance, for example at their homes, the recorded signals being transmitted to a monitoring centre and allowing sleep specialists to analyze the evolution of the patient.

The long term monitoring of human respiratory dynamics plays a very im-

portant role in the diagnosis and treatment of a number of medical conditions such as hypertension, circadian rhythm analysis, atherosclerosis, stroke, or even sudden death syndrome. Long term respiratory monitoring is a widely used method in the diagnosis of obstructive sleep apnea (OSA).

Respiratory rate (RR) is a physiological parameter used by some wireless monitoring systems as it allows the assessment of OSA, as RR can be recorded promptly and normal and abnormal variations can be easily differentiated.

A widely used method for the diagnosis of sleep-related diseases is polysomnography that records a number of physiologic variables including brain and heart activity, patient motion, RR, or oxygen saturation. However, polysomnography test is expensive, requires well trained medical personnel and keeps the patient in hospital overnight with many electrodes and sensors attached to him. To overcome these problems, numerous systems for home sleep monitoring are already in use. For example, some respiratory activity monitoring methods use thermistor based sensors (2), others use piezoelectric elastic bands placed around the chest (3), dual frequency microwave radars (4) or respiratory inductive plethysmography (5). Other methods use the ECG signals to extract the RR (6). All these, although acceptable for shorter periods of time, involve sensors attached to patient, connected by some unwieldy wires to monitoring devices that are not very comfortable for the sleeping patient. In order to avoid this situation, our system uses low power wireless devices and radio transceivers.

Many available home systems are not adequate for monitoring as they require the patients to be in conscious state able to press the alarm button. Other systems record the sleep data on a memory card and process the signals the next day, making them improper for real time operation. To solve this problem, we propose a wireless sensor system for real-time sleep apnea detection which enables remote monitoring while the patient is at home.

This paper describes a remote respiratory monitoring system for the detection of sleep disorders based on wireless sensor nodes. The sensor nodes contain commercially available modules that are connected together, perform the measurements, compute the results and transmit them to a central monitoring station. The central monitoring station runs a patient RR monitoring application that displays the RR in real-time and activates the alarms when an OSA episode is detected.

MATERIAL AND METHODS

The proposed remote monitoring system for sleep disorder detection (fig.1) consists of a wireless sensors network (WSN) used to measure the RR and transmit it to a central monitoring station running a patient RR monitoring application. Each sensor node in the WSN contains a wireless low power device attached to the sleeping patient used to compute the RR. There are also several repeater nodes distributed in WSN at fixed location, their number and density depending on the specific coverage requirements. An access point acting as a WSN coordinator is connected to the monitoring station through a USB connection. The central monitoring station running a patient RR monitoring application that receives the RR data from WSN, displays it as temporal waveforms, and activates the alarms when an OSA is detected.

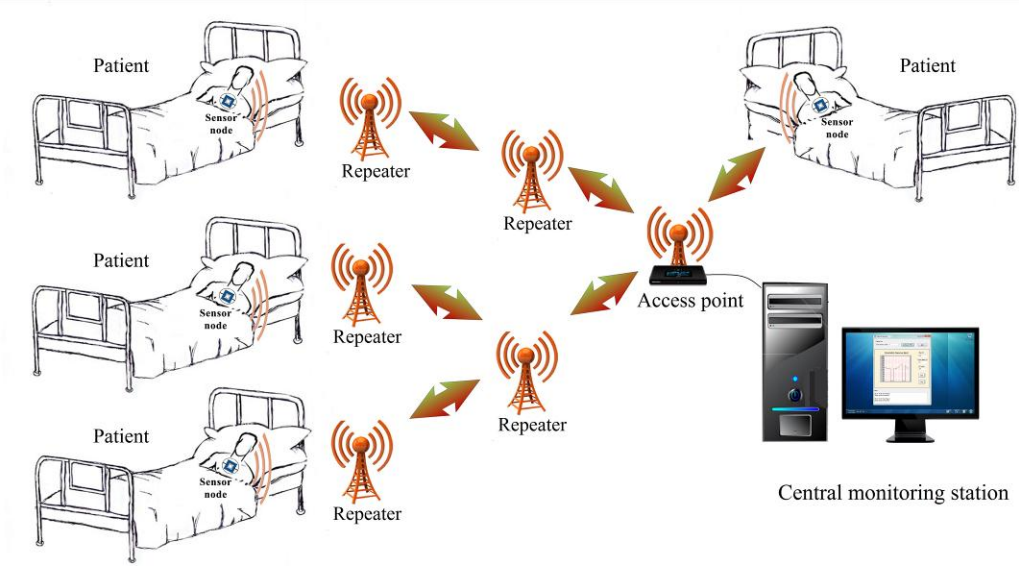

Fig. 1. Remote respiratory monitoring system – network architecture

Each sensor node contains an eZ430RF2500 circuit (Texas Instruments) (7). The eZ430-RF2500 is a complete wireless development tool for the MSP430F2274 microcontroller and CC2500 wireless transceiver that includes all the hardware and software required to develop a WSN in a convenient USB stick. MSP430F2274 is a 16-bit RISC ultra-low-power mixed signal microcontroller, has a memory structure that includes a 32 kb flash memory and 1kb on-chip SRAM. Other features of the MSP430 include: two built-in 16-bit timers, a fast 10 bit 200 kbps A/D converter with internal reference, enhanced universal serial synchronous/asynchronous communication interfaces USART, I2C, SPI. The internal digitally controlled oscillator allows wake-up from low-power modes to active mode very fast, facility that is used to extend batteries life.

The CC2500 wireless transceiver is a low-cost 2.4 GHz transceiver designed for very low-power wireless applications. The circuit uses for data transmission the 2400 MHz ISM (Industrial, Scientific and Medical) and SRD (Short Range Device) frequency bands, supports various modulation formats, has a configurable data rate up to 500 kBaud, and consumes less than 21.2 mA in transmission mode at 0 dBm output power and 17.0 mA in receiving mode.

We used the SimpliciTi protocol from Texas Instruments to transfer data from sensor node to central monitoring station. SimpliciTI is a proprietary, low-power radio-frequency network protocol used with small-scale WSNs that requires less memory than the widely used ZigBee protocol. This network contains battery-operated devices which require long battery life, low data rate, and have a limited number of nodes talking directly to each other. SimpliciTI network protocol supports End Devices (ED) in a peer-to-peer network topology, an Access Point (AP) to store and forward the data, and Range Extenders

(RE) to extend the range of the network.

Airflow detection using a nasal thermistor is one of the most frequently used methods to sense breathing pattern. Thermistors are electric circuit elements made of semiconductor materials that are characterized by a high negative temperature coefficient (NTC) or a high positive temperature coefficient (PTC). A NTC thermistor acts like a resistor, with temperature coefficients of typically –3% to –5%/ºC. The high sensitivity allows the thermistor circuit to detect minute changes in temperature, which could not be observed with other temperature detectors such as a thermocouple circuit. Thermistors placed in front of a nose detect the inspiratory and expiratory temperature fluctuations between ambient temperature (inhalation) and lung temperature (exhalation). It is known that the difference in temperature between the inhaled and exhaled air is about 10°C. We use two 0603 SMD type thermistors (fig. 3) with the following characteristics: R_{nom} = 10 kΩ at 25°C, B = 3380, 5% tolerance, connected as in fig. 2.

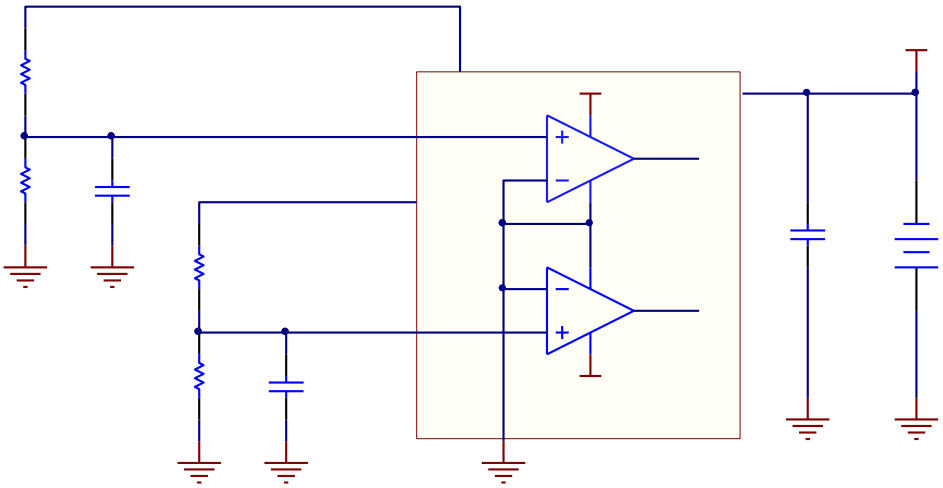

Fig. 2. Thermistors to MSP430F2274 microcontroller interface

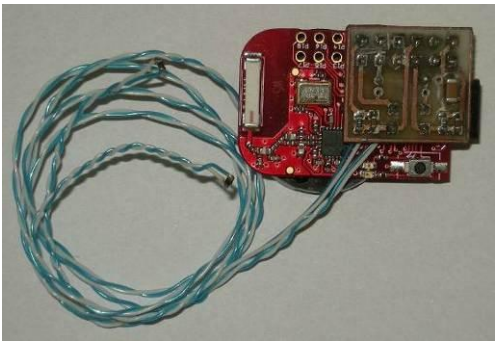

Fig. 3. Thermistor

Fig. 4. Chest belt

Another wireless device uses Pneumotrace II chest belt respiration transducer. The chest belt is a rugged, piezo-electric respiration transducer, which linearly generates a high level signal in response to changes in thoracic circumference associated with respiration. It generates 20 to 200 mV into a 1 MΩ load. Practically, for signal acquiring we use the same device, replacing the thermistor with the chest belt (fig. 4).

Power supply to the devices in fig. 3 and fig. 4 is provided by a CR2032 lithium battery and the A/D sampling frequency is 20 Hz.

A third wireless device uses a small accelerometer to detect the chest movements associated with respiration. It is a three-axis accelerometer (ADXL330 – fig. 5) with buffered outputs, connected to the 10 bit A/D inputs of the MSP430F2274. ADXL330 has the following technical specifications: 3-axis sensing, small, low power consumption: 200 μA at VS = 2.0 V (typical), single-supply operation: 2.0 V to 3.6 V, excellent temperature stability. The typical sensitivity shift over temperature for supply voltages of 3 V is typically better than ±1% over the −25°C to +70°C temperature range. To detect the RR, accelerations signals from the three axes are acquired at a sample rate of 20 Hz, 10 bit/sample, then the microcontroller identifies the peaks in the filtered acceleration signal $a = \sqrt{a_x^2 + a_y^2 + a_z^2}$, where a_x, a_y and a_z are accelerometer outputs (fig. 6).

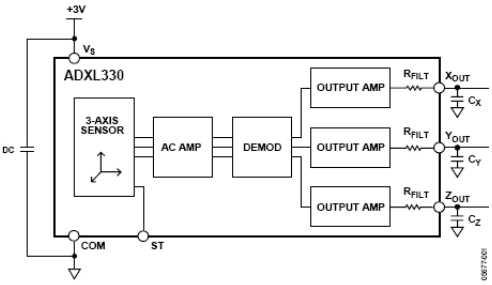

Fig. 5. Functional block

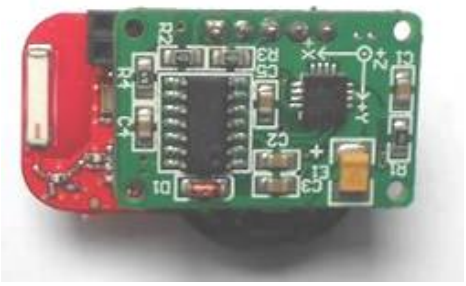

Fig. 6. Accelerometer diagram for ADXL330

RESULTS AND DISCUSSION

The flowchart of the software running on MSP430F2274 microcontroller in each node of the sensor network, including radio communication, is presented in fig. 7. After initializing, authentication and a START command, the sensor node wakes up to read and process the analogue signals. To minimize the energy waste, since an important power consumer is the radio transceiver, CC2500 enters a low power mode after each transmission cycle.

A user-friendly Graphical User Interface (GUI), running on the central monitoring station, was developed for real-time RR monitoring and apnea alert. GUI was developed by using LabWindows/CVI (fig. 8). On the GUI, temporal waveform of RR signal for selected patient are displayed, and the status of each sensor node (the battery voltage and the measured power from the received radio signal, used as

estimation for the distance between the wireless pacemaker and nearest Range Extender or Access Point).

The prototype of the above described system has been implemented and tested. The RR of three patients was computed by the wireless devices described above, and transmitted via WSN to the central monitoring station. The GUI running on the monitoring station displayed the RR correctly. Then, some apnea events (pauses in breathing lasting at least 10 seconds) were simulated, and the interface also displayed these alerts correctly.

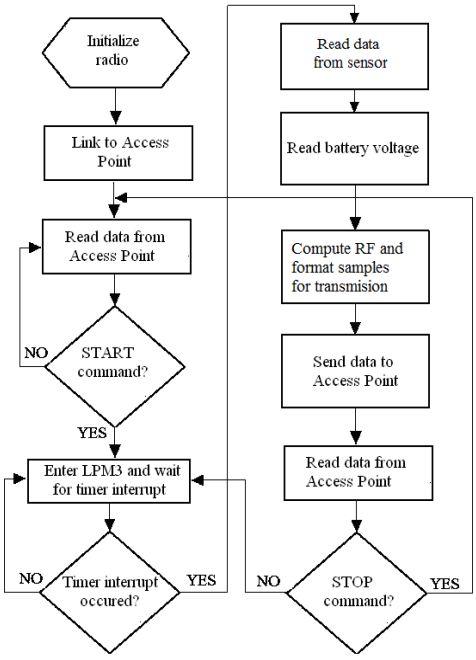

Fig. 7. Flowchart of the software

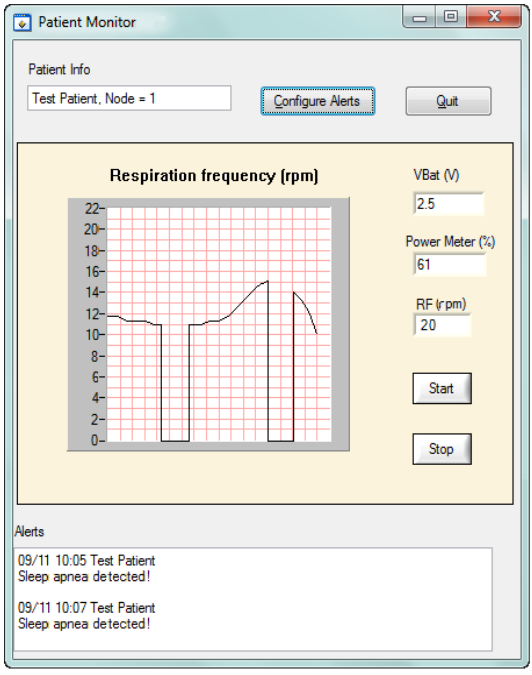

Fig. 8. Graphical user interface (GUI) running on MSP430F2274

Finally we measured the power consumption of the each sensor node. Knowing that CC2500 wireless transceiver is the largest contributor to overall power consumption, the average per-node estimate of power consumption is 0.44 mA. Calculating the battery life span (lithium battery 2240 mAh) ideally assuming that batteries maintain constant terminal voltage throughout life span, we obtained a value of approximately 23 days.

CONCLUSIONS

The prototype of a flexible, scalable and cost-effective medical remote monitoring system for the detection of OSA has been developed, implemented and tested. The system is suitable for continuous long-time monitoring of human respiration for a number of medical conditions requiring analysis of respiratory rate, sleep-related respiratory disorder or ischemic heart disease.

The described system allows persons with respiratory diseases or elderly to be

monitored at home, as an alternative to medical supervision in hospitals.

NEWS

CD35 PROTEIN AND EPSTEIN-BARR VIRUS

Epstein-Barr virus (EBV) is member in the human herpesvirus family. EBV affects nine out of 10 people and can cause infectious mononucleosis. Also it was the first human virus found to be associated with several types of cancer and with autoimmune disorders. To enter into the host cell, EBV attaches to the receptor CD21 of the primary B-cell membrane complementary with envelope glycoprotein EBV gp350/220. A recent study conducted by Fingeroth and Ogembo, show that the EBV glycoprotein gp350/220 is able to bind also a second receptor represented by the CD35 protein. This protein, which exists only in humans, was identified as a malaria receptor and as target in autoimmune diseases. Researchers showed that the CD35 receptor has a role in primary infection and reveals the importance of EBVgp350/220 for the development of a vaccine able to prevent or reduce the risk of infectious mononucleosis and EBV-associated pathology (Ogembo JG, Kannan L, Ghiran et al. Human Complement Receptor Type 1/CD35 Is an Epstein-Barr Virus Receptor. *Cell Reports*, 2013; 3 : 371-85).

PROPROSTHETIC INTERVENTIONS IN THE POSTERIOR MAXILLARY IMPLANT THERAPY (Abstract): **Aim**: The purpose of this study is to evaluate the necessary number of pro-prosthetic interventions in view of the implanto-prosthetic rehabilitation of the defective prosthetic fields. **Materials and methods**: We investigated a lot that included 230 patients aged between 18 and 82 who benefited from implant-prosthetic rehabilitation, the type of graft used, the types of membranes selected as well as the various remodeling and elevation techniques at the maxillary level dictated by the particularity of the clinical case**. Results and discussions**: The edentulous posterior maxillary region presents in implantology a more difficult situation than any other region of the maxillary. The absence of teeth often triggers a progressive reduction of the alveolar process volume, a reduction that aims particularly at the bony vertical dimension, namely the region between the top of the alveolar ridge and the floor of the maxillary sinus, called the sub-sinus Misch vertical dimension. The presence of the maxillary sinus, combined with the reduction of height of available bone in the terminal maxillary region poses serious problems for implant insertion. **Conclusions**: The success of the implant therapy depends on the absence of radio-transparent areas, while the per-implant bone resorption must be limited to the cervical region and should not involve the implant threads or its osteo-integrated area. The implant should also be fix, pain free, with no local infection. **Keywords**: IMPLANTS, PREIMPLANT SURGERY, AUGMENTATION, ORAL REHABILITATION.

The main success factors of the implant therapy are related to the preimplant augmentation surgery, The three-dimensional optimum and precise positioning of the implant, The Management of peri-implant soft tissues, Implant axis compatible with prosthetic options, The quality of prosthetic restorations (1).

Pre-implant surgery of augmentation is absolutely necessary to ensure a good osteo-integration, as well as a good stability over time of the implant (2).

The purpose of this study is to evaluate the necessary number of pro-prosthetic interventions in view of the implanto-prosthetic rehabilitation of the defective prosthetic fields.

MATERIAL AND METHODS

We investigated a lot that included 230 patients aged between 18 and 82 who benefited from implant-prosthetic rehabilitation, the type of graft used, the types of membranes selected as well as the various re-

modeling and elevation techniques at the maxillary level dictated by the particularity of the clinical case.

RESULTS AND DISCUSSION

The edentulous posterior maxillary region presents in implantology a more difficult situation than any other region of the maxillary. The absence of teeth often triggers a progressive reduction of the alveolar process volume, a reduction that aims particularly at the bony vertical dimension, namely the region between the top of the alveolar ridge and the floor of the maxillary sinus, called the sub-sinus Misch vertical dimension. The presence of the maxillary sinus, combined with the reduction of height of available bone in the terminal maxillary region poses serious problems for implant insertion (3).

The bone structure of the sinus walls is mainly composed of compact tissue. However, in certain areas there is a spongy tissue that fills in the gaps between the corticals, especially at the level of inferior areas (the floor of the sinus maxillary) (4).

According to Misch's bone density, it can be argued that in most cases the bone tissue in this area is mainly of D2-D3 class and, especially in the distal areas of the edentulous alveolar processes, D4 class (4).

Howell and Cawood's experimental studies showed that in the presence of teeth there is a centrifugal type circulation: the blood comes mostly from the arteries inside the bone tissue and partly from the blood vessels from the periosteum.

The edentulous alveolar process suffers from an ongoing resorption and its circulatory pattern becomes centripetal; most of the blood comes from the periosteum, while the intrinsic vascular component is greatly reduced. In agreement with the theory of Moss' oro-functional conformations, the loss of maxillary volume that follows the tooth loss is attributed to the following factors:

- the reduction of the centrifugal blood contribution through the atrophy of the vessels of the superior dental plexus;
- the pneumatization of the maxillary sinus towards the alveolar process, which is no longer hindered by the functional bone remodeling of mastication;
- the reduction of the centripetal blood contribution caused by the sufferance of the soft tissue in the case of removable dentures carriers.

The mucous membrane of the maxillary sinus is similar to that of paramaxillary sinuses, but less vascularized.

The thickness of the membrane is variable, generally ranging between 0.3 - 0.8m.

The maxillary sinus is linked to the nasal fossa through the ostium, infundibulum and middle meatus. These structures are called the osteomeatal complex. Of a particular importance is the fact that this opening is situated in the upper part of the maxillary sinus.

The adequate reflection and lifting of the sinus membrane and the insertion of the bone graft is possible without affecting the sinus drainage and improve the quality of life (5).

Until the first half or 1970, the maxillary sinus was considered an inviolable anatomic limit in implantology. With the rapid development of implantology, the need for surgical techniques to allow the augmentation of the atrophied alveolar process emerged, especially in the distal region of the upper alveolar maxillary arch.For exemplification, we show patient A.C, 43 years old, who had the following condition (fig.1).

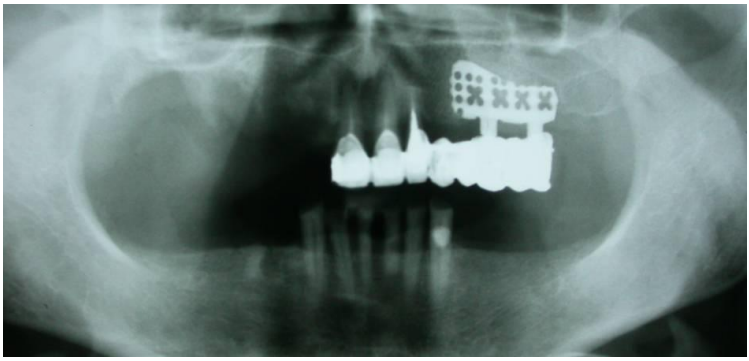

Fig. 1. Paraclinic OPT examination

After removing the existent implants, the case was evaluated again and the fix implant therapy was decided as a therapeutic solution, thus recreating the integrity and functionality of the stomatognathic system. Because the prosthetic field was defective from the odonto-periodontal and mucous-bone point of view, surgical interventions were necessary to readjust the two supports, in order to ensure the viability of the solution (fig. 2).

Thus, in a first stage, the regularization of the edentulous ridge in quadrant I was necessary, as well as the proposthetic preparation in view of the implant (fig. 3 a,b). The regularization of the alveolar ridge involved the realization of a mucous-periostal flap, the evidencing of the bone support and the removal of bone irregularities with the bone drill, followed by the suture of the alveolar ridge.

a. ***b.***

Fig. 3 (a,b). Regularization of the edentulous ridge

In a next stage the implants sites were created and the implants of the teeth corresponding to spaces 13, 15, 12.At the level of second premolar 13 a tuareg swell implant was chosen, with the following dimensions: 3.3x10 (fig.4 a,b,c,d).

For 15a tuareg sp implant was selected 4,2x11 (Fig. 5 a,b,c,d,e)

Tooth 12 was substituted by means of a tuareg s implant 3,5x10 (Fig. 6 a,b,c,d)

Because the bone support was deficient, we opted for a bone addition of Bio-Oss, as well as for the placement of a membrane, augmentation materials which will remedy the deficit of hard bone, contributing to a primary and secondary stability of the implants (Fig. 7 a,b,c,d,e, f,g).

The pro-prosthetic treatment included the apical resection at level 11.

CONCLUSIONS

The success of the implant therapy depends on the absence of radio-transparent areas, while the per-implant bone resorption must be limited to the cervical region and should not involve the implant threads or its osteo-integrated area. The implant should also be fix, pain free, with no local infection.

CURRENT MICROBIOLOGICAL DATA ON LOWER RESPIRATORY TRACT INFECTION IN CYSTIC FIBROSIS. PART II: RECOMMENDATIONS FOR MICROBIOLOGICAL DIAGNOSIS IN CYSTIC FIBROSIS (Abstract): Current standards of sputum examination in respiratory infections with opportunistic bacteria cannot be applied to patients with cystic fibrosis due to their particularities. In 2010, a working group from Great Britain established standards for microbiological processing of samples from patients with cystic fibrosis. Recommendations on sample collection, transportation, storage, and processing, identification of bacterial isolates and *in vitro* antibiotic susceptibility are made. Also recommended is that the multidisciplinary team monitoring patients with cystic fibrosis to include a microbiologist. **Key words**: CYSTIC FIBROSIS, LOWER RESPIRATORY TRACT INFECTION, OPTIMIZATION OF MICROBIOLOGICAL DIAGNOSIS.

Current standards of sputum examination in respiratory infections with opportunistic bacteria (1, 2, 3) cannot be applied to patients with cystic fibrosis (CF) due to the previously detailed particularities (4): onset of clinical manifestations in the first year of life, diverse pathogen population with different degrees of implication in the worsening of respiratory insufficiency, difficulties in identifying some of them to species level by conventional techniques.

In these circumstances, expert groups from North America and Europe became concerned with the optimization of microbiological evaluation of samples from lower respiratory tract (LRT) in CF patients as the therapeutic decision and infection control depend on it (5, 6, 7). The main recommendations in the latest guidelines drafted by a working group from United Kingdom in September 2010 (8) are presented, being of interest for all microbiologists dealing with such cases. Quality of care for these patients depends on the introduction of these rules in current practice.

Sample collection, transport, and storage

Sputum is the recommended specimen for routine investigation in patients, both at each hospital visit and during exacerbations. Sputum is of equal value as specimens taken during surgery or by bronchoscopic bronchoalveolar lavage (the golden standard for the investigation of LRT infections). In infants and small children hypo pharyngeal aspirate is recommended as it is a simple and non-invasive method. Pharyngeal exudate is not indicated because of false-positive results.

For best results, the samples have to be processed as soon as possible after collection. Any delay in processing with storage at room temperature can cause bacterial overgrowth which could mask the true pathogens. On the other hand, refrigeration at 4˚C for 2-3 hours does not significant negative consequences. Thus, if processing is delayed, refrigeration is preferable to storage at ambient temperature. .

Sample processing

Homogenization. Numerous studies recommend sputum homogenization of by mechanic disruption with glass beads or by mucolytic agents. However, the British expert group believes that there is insufficient evidence to support the requirement of using homogenization in CF.

Sputum Gram stains. Generally, this is a very important method which allows rejection of unrepresentative samples, and for the representative ones it gives quick information about morphology and staining characteristics of bacteria associated with inflammatory cells, and guides etiolology and empirical antibiotic therapy. In CF there is insufficient evidence to recommend it for routine use as a method for assessing specimen quality and to predict culture results.

Conventional culture. Unlike other respiratory infection, in CF the use of selective medium in addition to usual culture medium (blood agar, chocolate agar) is mandatory; prolonged incubation time leads to higher detection rates of three major pathogens: *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Burkholderia cepacia* complex (BCC). Their presence should be reported irrespective of quantity.

For *S. aureus*, Chapman medium incubated at 35-37˚C in air and examined next day and after at least other 24 hours is recommended. *P. aeruginosa* can be isolated in good conditions on MacConkey agar incubated at 35-37^{0}C in air and examined next day and after at least other 24 hours. This medium did not give satisfactory results in the isolation of BCC. BCSA medium (***B**urkholderia **C**epacia **S**elective **A**gar*) with polymyxin, gentamicin and vancomycin has a high sensitivity and specificity for BCC as compared to other selective media (9, 10), being thus recommended. To maximize sensitivity, it should be incubated at 35-37˚C in air for 5 days, with daily culture examination.

Haemophilus influenzae is a frequent commensal in the upper airways that may be a sputum contaminant, reason why quantitative evaluations are recommended. Growth on cefsulodin chocolate agar favors the isolation by inhibitory effect against *P. aeruginosa*. Incubation 35-37^{0}C in CO_2 at 35-37˚C for 24-48 hours.

According to the guidelines, the use of selective medium for *Stenotrophomonas*

maltophilia and other Gram-negative bacilli should be considered by laboratories according to their particular clinical needs.

Culture and identification of atypical mycobacteria is a matter for specialized laboratories.

For the isolation of filamentous fungi Sabouraud medium with additional antibiotic (ciprofloxacin, amikacin, ceftazidime or polymyxin) to inhibit *P.aeruginosa* should be used. Plate should be incubated at 35-37˚C for 24-48 hours, then prolonging cultures up to 7 days at room temperature (22^0C).

There is not sufficient evidence to support the use of molecular assays for the detection of microbial agents in CF in addition to routine culture.

Identification of bacterial isolates

Phenotypic identification to species level of isolates from LRT in CF is particular challenging for non-fermentative Gram-negative bacilli. *P. aeruginosa* strains can be accurately identified by the presence of three phenotypic characters: colonies with blue-green pigmentation (pyocyanin), positive oxidase test and growth at 42˚C. Growing strains displaying unusual characters can be misidentified as other Gram-negative non-fermentative bacilli: *Achromobacter* spp, BCC, *Burkholderia gladioli, Pandoraea* spp, *Ralstonia* spp, *S. maltophilia,* with important clinical and therapeutic consequences. An "excellent" identification from API 20NE kit (BioMerieux) in conjunction with colonial appearance, oxidase test, and colistin susceptibility can be used to confirm *P. aeruginosa, S. maltophilia, and Achromobacter* spp. This does not apply to a "very good", "good", or "acceptable" result due to a significant percentage of false-positive results; in these cases molecular techniques should be used by referring laboratory. However, BCC strains suspected by phenotypic methods should be immediately reported to the clinic, and immediate measures for preventing contact with other non-infected patients should be taken.

Additional molecular typing is recommended to identify strains with epidemiogenic potential.

Susceptibility testing guidelines

Antibiotic susceptibility of strains with clinical significance should be assessed by a standard method (CLSI, EUCAST); disc diffusion provides results comparable with broth dilution method (reference method). Automated testing is not recommended for Gram-negative non-fermentative bacilli due to possible major errors.

A good correlation between susceptibility findings and clinical response was found in patients intermittently infected with *P. aeruginosa.* In patients with initial infection, early treatment with appropriate antibiotics resulted in a much slower progression to chronic infection. In chronic infections, the presence of glycocalyx containing slow-multiplication bacteria makes that antibiotic therapy guidance by *in vitro* tests to be unsatisfactory. Currently there are no specific breakpoints for this condition.

Multidisciplinary team

The microbiologist, as laboratory service provider and infection prevention adviser, should participate in the meetings of the multidisciplinary team monitoring CF patients whenever particular situations are identified.

ESTIMATION OF DIETARY INTAKE OF CADMIUM AND LEAD THROUGH FOOD CONSUMPTION (Abstract): Cadmium and lead are toxic metals occurring in the environment naturally and from anthropogenic activities and can lead to chemical contamination of products entering in the human food chain. The consumption of polluted food is the main source of lead and cadmium intake in the non-smoking population. Lead is a heavy metal that can affect different organs and systems in humans including the peripheral and central nervous system, the gastrointestinal tract, muscles, kidneys, and the hemopoetic system. Neurological symptoms can range from fatigue, headache, and lethargy to peripheral neuropathy, severe convulsions, encephalopathy, and even coma. The direct neurotoxic actions of lead include apoptosis, excitotoxicity. Lead has been associated with impaired neurobehavioral functioning in children, decrements in intelligence quotient (IQ) while the critical effect of long-term exposure to cadmium is renal tubular dysfunction, which is irreversible; chronic renal failure is the final and severe endpoint. Cadmium is able to induce bone damage (*Itai-Itai*). The body burden of cadmium and lead depends mostly on the dietary intake of these elements. This paper aims to present a brief overview of cadmium and lead contents present in foodstuffs from different countries and the estimated dietary intake of cadmium and lead through food consumption. It has been shown that in some countries the concentrations of cadmium and lead contained in foodstuffs are higher than normal therefore the health of the people consuming them is at threat. **Key words**: CADMIUM, LEAD, DIETARY INTAKE

Toxic metals can be found as environmental contaminants, both through natural occurrence and as a result of human activities (1, 2, 3). Overmuch accumulation of toxic metals in agricultural soils from various sources, may not only result in soil contamination, but also may lead to high toxic metal uptake by crops, and thus affect food quality and safety (2, 3).

Diet is the main route of exposure to these heavy metals in the case of non-smoking population (3) therefore, Codex Committee for Food Additives and Contaminants suggested that dietary intakes of toxic metals with high public concern must be kept under surveillance and updated to identify recent dietary intakes of toxic metals in developing countries. Despite the fact that metals can change their chemical form, they cannot be degraded nor destroyed, thus, the risk evaluation of these elements through dietary intake is an important problem (4).

DIETARY EXPOSURE TO CADMIUM AND LEAD – HEALTH EFFECTS

Cadmium and lead, especially the inorganic forms, are highly toxic to humans. A large number of studies have shown that exposure through food to these toxic metals can have negative health consequences which can include anemia, renal dysfunctions, bone damage and neurobehavioral problems (1, 2).

CADMIUM. Cadmium absorption from the gastrointestinal tract is less than 5%, however the absorption can get higher if the body stores of iron, calcium or zinc are low (3, 4). Following absorption, cadmium binds to high molecular weight proteins in the blood and is transported to the liver, where it is bound to metallothionein (MT-low molecular weight, cysteine-rich protein) forming a Cd-MT complex (5).

The complex is reabsorbed in the kidney tubuli after glomerular filtration and then is stored in the kidney with a half-time of 10-30 years (2, 5). The first manifestation of cadmium nephrotoxicity is renal tubular dysfunction. The resorption function of the proximal tubules is affected, manifesting as an increase in the urinary excretion of low-molecular-weight proteins (tubular proteinuria), calciuria, glycosuria (4), and it has been detected at concentrations greater than or equal to 50 μg/g wet weight kidney cortex (6). The most suitable biomarkers for renal pathology are: urinary β2-microglobulin, α1-microglobulin and retinol-binding protein (RBP) levels.

It is also known that the ingestion of cadmium over a long period of time can cause bone damage (*Itai-Itai*). The disease is characterized by symptoms similar to those found in osteomalacia and osteoporosis combined with kidney damage (5). International Agency for Research on Cancer (IARC) has classified cadmium as being carcinogenic to human (group 1). Recently, it has been found that there is a significant positive association between cadmium intake from food and the risk of postmenopausal endometrial cancer (7). Also, it is known that cadmium can induce testicular injury because cadmium-induced oxidative stress may be responsible for some reproductive dysfunctions (reduced sperm count, reduced semen quality) (8).

LEAD. Lead is also a toxic metal which affects multiple organs and systems, including the central and peripheral nervous system, the red blood cells, the cardiovascular system and the male and female reproductive system (2, 4). Cereals, sea products and vegetables are the main sources of lead intake from foodstuffs for adults and children (9). The absorption of lead is about 3-10% in adults and up to 50% in children. The absorbed lead is transported by red blood cells, bound to thiol groups and other ligands in proteins (δ-aminolevulinic acid - the main binding ligand). Lead is transferred to soft tissues such as liver and kidney and to bone tissue, where it accumulates. In humans, the half-life of lead is approximately 30 days in blood and 10–30 years in bone (2). For children, there are a lot of studies which sustain the association between blood lead levels and impaired neurodevelopment (specifically reduction of intelligence quotient) (10) or neuropsychiatric disorders such as attention deficit hyperactivity disorder and antisocial behavior (11) at very low blood lead levels (BLLs) (2-10 μg/dl). For adults, BLLs higher than 1.9 μg/dl but lower than 10 μg/dl have been associated with increased risk for hypertension and increased cardiovascular mortality (2, 12).

Lead is known to interfere with heme synthesis inhibiting the activity of δ-aminolevulinic acid dehydratase and fer-

rochelatase, thus producing hematological effects (2). *In vitro* studies have shown that the inhibition of these 2 vital enzymes interferes with porphyrin synthesis leading to anemia (2, 13).

Cadmium and lead are known to affect the sexual maturation in children. Recently, Gollenberg et al. (14) have associated low blood lead and cadmium levels with delayed onset and progression of puberty in young girls, thus highlighting the importance of Pb and Cd as reproductive toxicants.

Therefore it should be noticed that the difference between the dietary intake of cadmium and lead by the general population and the concentrations at which toxic effects occur is very small and could be smaller for smokers (2, 3).

CADMIUM AND LEAD IN FOODSTUFFS – POLLUTION SOURCES

Both cadmium and lead are ubiquitous environmental pollutants. The most important sources of food contamination with cadmium and lead include chemical fertilizers, food processing equipment, exhaust fumes from vehicles, industrial gases, wastewater used for irrigation. Cereals, fruits and vegetables cultivated on soils polluted with toxic metals retain large enough quantities to constitute a major source of exposure to these toxics (2, 3).

CADMIUM AND LEAD CONTENT IN FOODSTUFFS

In a recent study, a committee from WHO (World Health Organization) estimated the content of cadmium and lead in some foodstuffs based on the data submitted by 30 countries. Mean concentrations of cadmium ranged between ND (not detected) and 4800 µg/kg (in shellfish and mollusks). Higher concentrations of cadmium were also found in dried vegetables, poultry offal and meat offal. High lead concentrations were determined in stimulants (coffee, tea and cocoas), vegetables, dried fruits and alcoholic beverages (4) (tab. I).

TABLE I

Cadmium and lead content in some foodstuffs (4)

Food category	No.of samples Cd / Pb	Concentration	
		Cd (µg/kg)	Pb (µg/kg)
Rice	2295 / 85	4-20	< LOD-4
Baked goods	55 / 203	ND-20	1-230
Cereals/grains, others	12637 / 5027	ND-30	< LOD-29
Roots and tubers	2319 / 1255	6-40	1-65
Fruits	6314 / 7480	1-7	< LOD-130
Dried fruits	79 / 282	3-9	6-340
Vegetables	18183 / 13402	6-100	< LOD-400
Dried vegetables	348 / -	90-1000	-
Shellfish / Mollusks	7403 / 765	10-4800	10-190

Stimulants (coffee, tea and cocoas)	3505 / 764	0,1-1800	< LOD-1030
Drinking water (bottled and tap)	21472 / -	ND-0,4	-

ND- Not Determined ; LOD – Limit of Detection

Toxic metal contents in foodstuffs cover a wide range (tab. II). The mean concentration of cadmium varies from 0.014 µg/kg wet weight in milk from Spain (15) and 650 µg/kg dry weights in Lavash bread from Iran (16). Seemingly, the mean concentrations of lead ranges from 8 µg/kg wet weight in meat (pork, beef) from Greece (17) and 746 µg/kg in sweets (candies and chewing gum) from Turkey (18). The sweets present high concentrations of cadmium and lead, therefore it represents a hazard for human health, especially for children due to high consumption of candies and chewing gum.

TABLE II

Cadmium and Lead content in foodstuffs from different countries

ESTIMATION OF DIETARY INTAKE OF CADMIUM AND LEAD

Because of the long half-life of cadmium and lead in the human body WHO decided to withdraw the previous PTWI (provisional tolerable weekly intake) for cadmium (7 µg/kg b.w.) and for lead (25 µg/kg b.w.) and proposed that the dietary intake of cadmium should be measured over a period of one month and a provisional tolerable monthly intake (PTMI) was established at 25 µg/kg body weight (4).

Winter-Sorkina et al. (24) calculated the dietary intake of cadmium and lead in Dutch population. Mean concentrations of dietary intake were 0.14 µg /kg b.w. (body weight)/day cadmium and 0.05 µg /kg b.w./day lead in general population. Jarup et al. (5) have estimated the average dietary intake of cadmium at 15 µg/day (0.22 µg/kg b.w./day) for the Swedish population. For the Korean children, Moon et al. (25) has estimated the dietary intake of cadmium from boiled rice at 2.22±0.84 µg/day and for lead at 0.79±0.3 µg/day (tab. III).

TABLE III

Daily dietary intake of cadmium and lead in different countries

Country	Food category	Concentration (µg/day)		References
		Pb	Cd

a- dietary intake of toxic metals for adult males;

b- estimated daily intakes for adults over 15 years and more

WHO has presented a report regarding the estimation of dietary intake of cadmium and lead (table IV).

TABLE IV

Estimation of dietary intake of cadmium and lead in the world (4)

Country/ region	µg Cd/kg b.w./month	µg Pb/kg b.w./day	Country/ region	µg Cd/kg b.w./month	µg Pb/kg b.w./day
Australia	2,2 – 6,9	0,02 - 0,93	Japan	12	-
Chile	9	3 - 9	Korea	7,7	-
China	9,9	0,9 - 3,1	U.S.A	4,6	0,03 - 0,13
Europe	9,1	0.36 - 3,1			

b.w.- body weight ;

CONCLUSIONS

After pointing out cadmium and lead concentrations in many foods, different values of toxic metals have been found, depending on the food category. The data reports submitted by FAO / WHO presented that cadmium levels in food are under PTMI. However, there are some countries where dietary intake of cadmium may endanger human health. Moreover, in countries where exposure to lead through food consumption is close to the maximum tolerable limit, the main sources of pollution should be identified and various methods to reduce exposure to these toxics should be applied.

NOUTĂȚI

HIPERTENSIUNEA ARTERIALĂ PULMONARĂ INDUSĂ DE DASATINIB

Registrul francez de hipertensiune pulmonară a permis semnalarea unor cauze noi, apărute în context iatrogen. De la aprobarea dasatinibului pentru tratamentul leucemiei cronice mieloide, în noiembrie 2006, şi până pe 30 septembrie 2010, au fost descoperite 9 cazuri de hipertensiune pulmonară precapilară, la pacienţi trataţi cu dasatinib. La patru săptămâni de la întreruperea tratamentului, s-a obţinut ameliorarea clinică, funcţională şi hemodinamică la toate cazurile, cu o singură excepţie. 2 pacienţi au necesitat tratament cu antagonişti ai receptorilor de endotelină şi unul cu blocanţi ai canalelor de calciu. După o urmărire medie de 9 luni (3 – 36 luni) pacienţii nu au obţinut remisiunea clinică şi hemodinamică: deşi ameliorarea a fost semnificativă, la nici unul dintre pacienţii urmăriţi presiunea arterială pulmonară medie nu a scăzut sub 20 mm Hg. În acest interval de urmărire, doi pacienţi au decedat, unul cu moarte subită şi celălalt cu sepsis şi insuficienţă cardiacă. Studiul atrage atenţia asupra efectului specific pe care administrarea de dasatinib l-ar putea avea asupra circulaţiei pulmonare, determinând hipertensiune pulmonară precapilară. (Montani D, Bergot E et al. Pulmonary arterial hypertension in patients treated by Dasatinib, *Circulation 2012*, 125: 2128-2137)

STUDY OF THE NUTRITIONAL STATUS AND EATING HABITS ON A GROUP OF PATIENTS IN PRIMARY HEALTH CARE (Abstract) **Aim**: Evaluation of medical and biological status of the study group; analyzing the nutritional status and the way of eating by food investigation; and evaluation of the knowledge about eating behavior and the role of physical activity in health. **Material and methods**: The study was conducted from 2010-2011 on a sample of 375 patients aged 18-74, patients within a family medicine cabinet in our town. The questionnaire included demographic data (age, education, social, financial situation, the belonging religious) and questions about nutrition on food groups and questions about rational knowledge about nutrition, eating behavior and the role of physical activity. **Results**: In the study group by gender distribution was 225 women (60%) and 150 men (40%) with a ratio F/M= 1.5/1 Evaluation of the nutritional status and somatometric exam revealed the following issues: 105 cases (28%) with,103 cases (27.46%), 52 cases (13.86%) 72 (19.2%) and 43 cases (11.46%).Most patients were overweight normo and 27.46% respectively 28% and is followed by those with grade II obesity (19.2%), obesity grade I (13.86%) and final grade III obesity(11.46%).The food investigation on food groups showed no significant differences between the two years of study configuring same eating behavior. **Conclusions**: Metabolic and nutritional diseases became increasingly aggressive in recent decades and obesity is a widespread disease in the population with a multifactorial etiology and with a chronic evolution. The family doctor been in the forefront of the health system can contribute to increasing the quality of life that heis monitoring the implementation of educational programs related to food andeating behavior.

Alimentația ca factor fundamental de mediu, reprezintă ştiința relațiilor biologico-medicale dintre alimente şi om, în toată complexitatea lor. Alimentația este socotită de unii autori ca fiind cel mai important factor de mediu întrucât are o influență considerabilă asupra organismului, iar efectele ei nu se observă întotdeauna imediat, ci cumulativ în timp. Viața nu poate fi concepută fără un aport exogen de nutrienți pe baza produselor alimentare ingerate, ceea ce permite încorporarea substanțelor nutritive în organism, constituind baza desfăşurării proceselor vitale. Asimilarea şi dezasimilarea continuă, prin transformarea şi metabolizarea substanțelor nutritive, oferă

materiei vii atât energia necesară întreținerii vieții în condiții de repaus şi efort, cât şi elementele materiale necesare refacerii structurilor celulare uzuale (1). Pentru desfăşurarea activității în condiții bune, organismul uman trebuie să primească zilnic o cantitate de energie şi factori nutritivi.

Alimentația rațională ca ştiință caută nu numai să apere organismul de efectele unui aport alimentar neadecvat, ci îi menține şi creşte vigoarea, performanța fizică şi intelectuală, fertilitatea, longevitatea, capacitatea de reacție şi de adaptare (2). Ingestia de alimente trebuie să fie întotdeauna suficientă pentru a asigura necesarul metabolic al organismului şi, în acelaşi timp, să nu depăşească nevoile pentru a nu cauza supraponderabilitate sau chiar obezitate. Alimentația rațională înseamnă un aport adecvat cantitativ şi calitativ conform cerințelor fiziologice.

Însuşirea unei alimentații raționale trebuie să urmărească următoarele obiective: asigurarea tuturor trofinelor necesare în cantități optime; asigurarea echilibrului şi proporției optime între trofine; realizarea unei concordanțe între nevoi şi aport; asigurarea unei bune stări de nutriție, realizată prin cunoaşterea valorii nutritive a produselor alimentare disponibile, în vederea alcătuirii unei rații complete şi echilibrate, a influenței proceselor tehnologice de preparare asupra alimentelor, precum şi a gradului de utilizare digestivă a hranei ingerate; asigurarea unei alimentații adecvate vârstei, activității profesionale, stării fiziologice ca şi în vederea creşterii rezistenței antiinfecțioase şi antitoxice a individului; alimentația trebuie să fie diversificată; asigurarea variației regimului alimentar; prevenirea nocivității alimentelor şi evitarea consumării unui produs alimentar insalubru, ceea ce presupune: cunoaşterea sursei agenților biologici şi chimici ce pot fi vehiculați de alimentație, mijloacele de prevenire, respectarea riguroasă a condițiilor igienico-sanitare pe tot circuitul alimentelor; proprietățile organoleptice ale alimentelor să corespundă deprinderilor consumatorilor; repartizarea rațională a rației alimentare în cursul zilei; asigurarea rației cu material fibros (efect enterokinetic) şi a unui volum corespunzător fiecărei mese; respectarea condițiilor fiziologice generale de alimentare: fixitatea orelor de masă, asigurarea unei ambianțe adecvate, ordinea felurilor de meniu, temperatură potrivită a alimentelor, acordarea unui timp suficient servirii mesei, etc. (4,5).

Termenul de comportament alimentar se defineşte ca un ansamblu de reacții adaptative, observabile obiectiv, prin care organismul privit ca un tot unitar, produce un răspuns la stimulii din mediu, el reprezintă procesul determinant al prizei alimentare spontane a unui individ (6,7).

Studiul nostru a avut urmatoarele obiective (i) evaluarea statusului biologico - medical al lotului de studiu (ii) analizarea starii de nutritie şi a modului de alimentație prin ancheta alimentara şi (iii) evaluarea cunoştințelor despre comportamentul alimentar şi rolul activitatii fizice in starea de sanatate.

MATERIAL ŞI METODĂ

În studiu au fost incluşi 375(28,2%) de pacienti din cei 1327 în vârstă de peste 18 ani, aflați în evidență ai cabinetului de medicina familiei care s-au prezentat la controlul medical periodic sau cu diferite acuze în perioada 1 februarie 2010 - 30 martie 2011. După semnarea consimțământului informat, subiecții au completat un chestionar şi au fost supusi unui examen clinic general.

Chestionarul include date demografice (vârstă, studii, mediul de proveniență, situație financiară, apartenănță religioasă) şi întrebări privind modul de alimentație cantita-

tiv şi calitativ, pe grupuri de alimente şi principii nutritive, şi cele referitoare la cunoştinţele legate de alimentaţia raţională, comportament alimentar şi rolul activităţii fizice. Pe lângă datele obţinute din completarea chestionarului, s-au luat în consideraţie: greutatea corporală, talia şi circumferinţa acesteia, pentru calcularea indicelui de masă corporală (IMC). În cadrul examenului clinic s-au analizat semnele şi simptomele pacienţilor, însoţit de evaluarea stării aparatelor şi sistemelor, înregistrându-se datele antropometrice şi valoarea tensiunii arteriale.

Prelucrarea datelor s-a efectuat cu ajutorul programului SPSS 16.0

REZULTATE ŞI DISCUŢII

1. *Caracteristicile lotului de studiu*. Lotul de 375 de pacienti cu o distributie pe sex de 225 (60%) femei şi 150 (40%) bărbaţi cu un raport F/M= 1,5/1. Au predominat cazurile de sex feminin provenite din mediul urban (48%), fara diferenţa semnificativă faţă de cazurile sex masculin (32%) comparativ cu distribuţia cazurilor din mediul rural (F=12% vs M=8%) (χ^2=0,09; GL=1; p=0,768).

Diferenţele procentuale în relaţie cu nivelul de instrucţie a evidenţiat: lotul de studiu cuprinde semnificativ mai multe femei cu nivel mediu de instrucţie comparativ cu bărbaţii (p=0,008); mediul de proveniență este preponderent urban la persoanele cu nivel mediu de instrucţie (p=0,008); nu s-au înregistrat diferenţe semnificative din punct de vedere statistic pe grupuri de vârstă; activitatea profesională incluzand pensionari, şomeri şi fără activitate cu nivel mediu de instrucţie (p=0,002); condiţiile socio-economice satisfăcătoare cu nivel mediu de instrucţie au fost predominante (p=0,015) (tab.I)

TABELUL 1

[a]pentru valorile mai mici de 10, proportiile sunt orientative

2. *Evaluarea stării de nutriție prin examen somatometric* prezintă o mare importanță pentru aprecierea stării de sănătate. S-au luat în considerare datele antropometrice: greutatea corporală, talia, circumferința taliei şi s-a calculat indicelui de masă corporală (IMC). Datele IMC au servit pentru împărțirea lotului în: normoponderali, supraponderali şi obezi. În paralel cu datele antropometrice s-a măsurat tensiunea arterială în vederea analizei acesteia în funcție de IMC şi s-a calculat circumferința taliei

Pe baza rezultatelor antropometrice obținute la cei 375 de pacienti analizati, şi prin calcularea IMC s-au evidentiat următoarele aspecte: 105 (28%) cazuri cu IMC intre 18,5-24,9 kg⁄m² (limite normale); 103 (27,46%) cu IMC intre 25-30 kg⁄m² (suprapondere); 52 (13, 86%) cu IMC = 30-33 kg⁄m² (obezitate gradul I); 72 (19,2%) cu IMC intre 35-40 kg ⁄ m²(obezitate gradul II) şi 43 (11,46%) cu IMC >40 kg⁄m² (obezitate gradul III) (fig. 1).

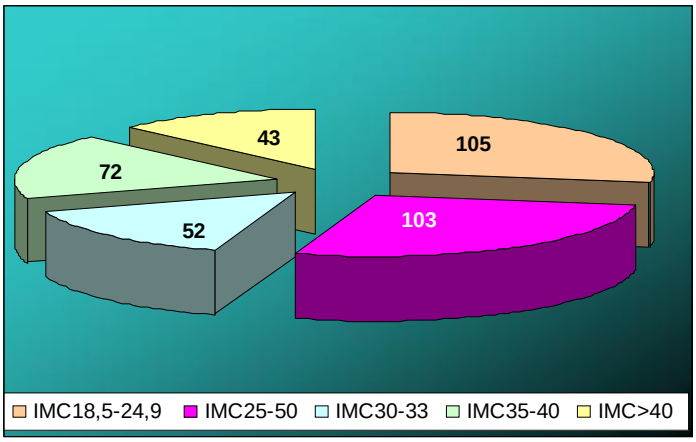

Fig. 1. Valorile IMC a pacienților studiați

Cei mai mulți pacienți sunt normo şi supraponderali, respectiv 28% şi 27,46%, fiind urmați de cei cu obezitate de gradul II (19,2%), de gradul I (13,86%) şi în final de gradul III 11,46%.

4. *Analiza chestionarului de ancheta alimentară* a evidentiat urmatoarele aspecte : ratia alimentara pe grupurile de alimente nu prezinta diferente semnificative in cei doi anii de studiu *Consumul de carne* a rezultat : pe parcursul anului 2010, procentul cel mai mare de persoane (46,40 %) consumă carne roşie de 2-3 ori pe săptămână, fiind urmate de persoanele ce consumă acest aliment o dată pe săptămână (18,60 %) şi de 5-6 ori pe săptămână (12,09 %). În anul 2011, pe primul loc s-a situat, de asemenea, consumul cărnii de 2-3 ori pe săptămână (40,60 %), urmând consumul o dată pe săptămână (22,90 %) şi pe locul 3 s-a situat consumul de 5-6 ori pe săptămână (7,30 %).

Consumul de peşte a fost de 46,40 % în 2010 şi 50,10 % în 2011 ; de 1-3 ori pe lună , urmat de o dată pe săptămână 30,90 % persoane în 2010 şi 31,10 % în 2011. A rezultat ca in lotul examinat au fost persoane care nu au consumat peste 8,80 % în

2010 şi 8,20 % în 2011 şi la polul opus s-au situat cei care au consumat de 2-3 ori pe săptămână (12,90 % în 2010 şi 10,40 % în 2011) şi chiar de 5-6 ori (1 %).

Consumul de lapte şi produse lactate a evidentiat că majoritatea persoanelor au consumat laptele şi produsele lactate o dată pe zi (41,70 % în 2010 şi 49 % în 2011), iar evaluarea consumului acestora pe săptămână arată o frecvenţă asemănătoare a consumului de 5-6 ori pe săptămână, de 2-3 ori pe săptămână şi o dată pe săptămână; în 2010 frecvenţele au fost cuprinse între 14,07 % şi 16,90 % iar în 2011 în jur de 14%.

Persoanele din lot consumă ouă cel mai frecvent o dată pe săptămână (41,20 % în 2010 şi 41,10 % în 2011), urmând consumul de 2-3 ori pe săptămână (20,40 % în 2010 şi 26,70 % în 2011), iar consumul de 5-6 ori pe săptămână se întâlneşte mai rar (1,60 %). De asemenea, nu poate fi omis faptul că există persoane care nu consumă "aproape niciodată" ouă (11,30 % în 2010 şi 7,90 % în 2011).

Consumul de fructe proaspete este deosebit de important la toate vârstele,si s-a evidentiat o frecvenţă crescută a consumului de 2-3 ori pe săptămână (33,60 % în 2010 şi 28,80 % în 2011) şi o dată pe săptămână (31,40 % în 2010 şi 31,50 % în 2011), urmând consumul de 5-6 ori pe săptămână (11,90 % în 2010 şi 10,80 % în 2011). Consumul de 1-3 ori pe lună se întâlneşte la 20,80 % dintre persoane în 2010 şi 25,80 % în 2011.

Prin evaluarea consumului de legume proaspete se constată că majoritatea persoanelor din lot consumă legume de 2-3 ori pe săptămână (32,60 % în 2010 şi 36,20 % în 2011) şi o dată pe săptămână (32,30 % în 2010 şi 28,90 % în 2011), situaţie întâlnită şi în cazul fructelor. Un procent relativ crescut se întâlneşte şi în cazul persoanelor care consumă legume proaspete de 1-3 ori pe lună (14,40 % în 2010 şi 13 % în 2011) şi un procent mai mare decât în cazul consumului de fructe se întâlneşte pentru cei care nu consumă "aproape niciodată" legume proaspete (9,70 % în 2010 şi 4 % în 2011).

S-a constatat că procente însemnate a persoanelor din lot sunt consumatoare de băuturi alcoolice de 5-6 ori pe săptămână şi de 2-3 ori pe săptămână, ceea ce reprezintă un factor de risc pentru multe boli cronice. Trebuie subliniat faptul că este foarte importantă cantitatea consumată de aceste persoane.

5. *Modul de manifestare al comportamentului alimentar* cuprinde una sau mai multe din urmatoarele forme: mese copioase care realizează un aport caloric mult mărit, pe seama tuturor principiilor nutritive, asociat de regulă cu consumul de alcool; persoane preocupate de hrană, mâncând rapid şi lacom; abuz preferenţial de lipide şi glucide; mese rare pe zi (de două ori pe zi), dar copioase. S-a invocat mai multe cauze pentru explicarea fenomenului de ingestie abuzivă a alimentelor, cele mai importante sunt: dereglarea apetitului, apariţia unei pofte de mâncare exagerate (hiperfagie), cauzată de traumatisme psihice, boli psihice sau ale sistemului nervos care afectează centrul saţietăţii din hipotalamus; ofertele crescute de hrană în cadrul unui meniu culinar familial; disponibilităţile crescute de hrană ca o consecinţă a bunăstării materiale; existenţa unui dezechilibru afectiv, cauzat de insuccese profesionale, de stări conflictuale, de lipsa satisfacţiilor emoţionale, plăcerea de "a gusta" în permanenţă "câte ceva". În aceste cazuri, hiperfagia este o modalitate de refulare; factorii hormonali care apar în circumstanţe speciale (în sarcină şi menopauză), deter-

minând creşterea apetitului (1,7).

6. *Evaluarea cunoştinţelor* de alimentație şi importanța activității fizice a evidențiat pentru pacienții incluşi în studiu că principiile unei alimentații raționale sunt insuficient cunoscute iar practicarea activității fizice este complet neglijată de pacienții din lotul de studiu.

CONCLUZII

În cercetările noastre a rezultat că există categorii populaționale care au comportamente nutriționale nesanogene. Astfel din cele 375 (28,2%) persoane aflate în asistența medicului de familie au beneficiat de un control medical periodic, cu ocazia căruia s-au realizat intervenții educaționale privind ritmul consumului săptămânal de carne, peşte, lapte şi derivate, ouă, fructe şi legume şi băuturi alcoolice.

Evaluarea cunoştinţelor de alimentație rațională a evidențiat pentru lotul inclus în studiu că principiile unei alimentații raționale, sanogene sunt insuficient cunoscute.

PROCALCITONINE - EARLY MARKER OF NEONATAL INFECTION (Abstract). Neonatal infection represents the third most important cause of mortality in Neonatal Intensive Care Units (NICU), following perinatal asphyxia and respiratory distress syndrome. The incidence varies according to the level of care, between 5% in level II neonatal wards and 20% in the NICUs. The lack of specific early markers for infection could be partially responsible for the lack of antibiotic treatment or unnecessary treatment. In this context, many variables were examined as markers for sepsis. Large concentrations of C-reactive proteine (CRP) and procalcitonine (PCT) were positively correlated with the severity of the infection and generally indicated a poor outcome. **Aim**: The aim of this study is to demonstrate the utility of PCT as a fast, early and routinely used marker of neonatal infection, correlated with CRP, clinical symptoms and blood cultures. **Materials and methods:** this is a retrospective-prospective study on 2 lots of newborns from two neonatal wards of different levels of care (Lot I – 32 newborns from the Cuza-Voda NICU in Iasi, born in 2010, Lot II – 127 newborns from the Buna Vestire Maternity in Galati, born during 2008-2009). PCT was assessed before the beginning of the antibiotic treatment in newborns with high risk of sepsis or newborns with proven sepsis as corroborated with complete blood counts, CRP, fibrinogen, clinical symptoms and blood cultures. **Results**: Among risk factors for neonatal infection, those found more often in newborns with proven sepsis are: ruptured membranes over 18 hours ($p=0.043$), Gram-negative bacilli colonization ($p=0.003$), respiratory distress syndrome ($p=0.0008$), abdominal distention ($p=0.0042$), oedema ($p<<0.05$) and necrotizing enterocolitis ($p<<0.05$). High values for PCT in premature newborns show the high risk for infection for this category of newborns, due to immunological imaturity and the presence of risk factors. High sensitivity and specificity of PCT (specificity =88.98%, sensitivity=87.5%) showed that the accuracy of PCT assessment in studied lots was 88.68% during the 24-72 hours of life time frame. **Conclusion**: High serum levels of PCT in studied lots plead for the usage of PCT for the fast and early diagnostis of neonatal infection. In those cases with positive PCT and negative blood cultures or positive CRP and clinical symptoms of infection, PCT would be a useful tool, aiding in the initiation or termination of antibiotic treatment, which would ultimately lead to lowering costs. PCT as a screening tool for cases with risk factors for infection is still to be analysed in terms of costs versus benefits and the longterm implications of neonatal sepsis and antibiotic treatment. **Key words**: NEWBORN, NEONATAL INFECTION, SEPSIS, PROCALCITONINE, C REACTIVE PROTEINE, BLOOD CULTURES

Diagnosticul infecției bacteriene la nounăscut este dificil de stabilit mai ales că din punct de vedere clinic simptomatologia este nespecifică şi se asociază de obicei cu o altă

patologie dată de factori non-infecţioşi care pot genera răspuns inflamator (asfixia nou-născutului, EHI, malformaţie de cord etc.). Testele diagnostice utilizate pentru identificarea răspunsului inflamator sistemic sunt sărace de asemenea şi confirmarea punctului de plecare a infecţiei în neonatalogie este extrem de greu de precizat.

Lipsa unor markeri precoce specifici pentru infecţie ar putea fi responsabilă parţial pentru întârzierea sau dimpotrivă instituirea fără necesitate a tratamentului antimicrobian. În acest context au fost examinate mai multe variabile ca markeri pentru sepsis. Concentraţiile mari ale CRP, procalcitoninei (PCT) au fost corelate pozitiv cu severitatea procesului infecţios indicând în general un prognostic nefavorabil.

Procalcitonina (PCT) creşte marcat în condiţii de sepsis şi pare a fi un bun indicator al severităţii infecţiei. Procalcitonina este eliberată în circulaţie în primele 3 ore de la pătrunderea endotoxinelor în organism, atinge platoul la 6h şi rămâne crescută timp de 24 h, face din acest marker un agent promiţător pentru identificarea precoce şi sensibilă a cazurilor infectate [1]. PCT nu este măsurabilă în serul indivizilor normali, însă titrul său creşte în infecţiile microbiene fungice şi parazitare, nu şi în cele virale.

Acurateţea procalcitoninei în diagnosticarea sepsisului precoce la nou-născut (infecţia bacteriană severă apărută în primele 72h de viaţă) este încă un subiect controversat.

PCT a fost propusă ca indicator al infecţiilor severe generalizate (sepsis). A fost documentat faptul că nivelurile PCT cresc odată cu severitatea răspunsului inflamator la infecţie. Mai mult, se pare că nivelul PCT se corelează cu prognosticul pacientului [2]. Scopul studiului este de a demonstra utilitatea PCT ca marker rapid precoce şi de rutină al infecţie neonatale corelat cu CRP-ul, cu simptomatologia clinică şi cu hemocultura.

MATERIAL ŞI METODE

S-a efectuat un studiu prospectiv şi retrospectiv pe 2 loturi de nou-născuţi din două maternităţi de niveluri diferite (Lot I – 32 nou-născuţi din CRTIN – Spitalul Clinic de Obstetrică Ginecologie „Cuza−Vodă" Iaşi în anul 2010, Lot II – 127 nou-născuţi din perioada 2008-2009, în Spitalul Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi). Nou-născuţii incluşi în studiu au prezentat factori de risc pentru sepsis.

În determinarea PCT s-a utilizat testul BRAHMS, test imunocromatografic pentru determinarea semicantitativă a procalcitoninei, utilizat pentru a demonstra şi controla tratamentul infecţiilor severe. Recoltarea probelor de laborator s-au efectuat înainte de tratamentul cu antibiotice, sângele recoltat s-a centrifugat şi serul obţinut (6 picături) s-a plasat pe un strip, după care s-a urmărit modificarea culorii în funcţie de standard. Citirea s-a efectuat după 30 min sau max. 40 min.

Interpretarea rezultatelor. PCT sub 0,5 ng/mL – este posibilă o infecţie bacteriană locală sau recoltarea s-a făcut precoce şi se va repeta după 6-24 ore. [3] Un interval de 0,5 şi mai mic de 2 ng/ml – este posibilă o infecţie sistemică severă, dar pot exista şi alte condiţii care cresc PCT (asfixia, traumatisme obstetricale, malformaţii congenitale de cord etc.). Între 2-10 ng/mL – este probabil o infecţie sistemică şi risc crescut de infecţie spre sepsis şi peste 10 ng/ml risc cu probabilitate înaltă de sepsis. Interpretarea valorilor PCT s-a făcut în coroborarea cu alte probe de laborator şi

semne clinice ale nou-născutului. Determinările au fost făcute în primele 72 ore. [4]

Au fost luați în studiu următorii factori de risc pentru infecție:

Factori de risc materni: MRS>18h, coriamniotita, colonizare cu streptococ de grup B-E. coli (SGB), infecție de tract urinar;

Factori de risc neonatali: naştere prematură (< 37 săptămâni), greutatea mică la naştere (<2500gr.)

Semnele şi simptomele clinice de sepsis au fost:

Semne clinice (+): detresă respiratorie (tahipnee, efort respirator etc.), distensie abdominală, drenaj gastric bilios, edem de perete abdominal, scleredem, EUN;

Semne de suspiciune de laborator: leucopenie (<5000 mm^3), leucocitoză (>30000 mm^3), CRP (>8mg %), Fb (>3,5), acidoză metabolică, icter cu BD;

Semne de certitudine: culturi pozitive din sânge.

PCT a fost determinată în situația de suspiciune clinică de infecție coroborată cu factorii de risc matern şi neonatali şi probe inflamatorii modificate (CRP, Fb, hemoleucograma). S-a făcut o singură determinare datorită cantității mici de teste şi prețul crescut al testului.

REZULTATE

Pentru a determina acuratețea PCT în diagnosticul sepsisului neonatal precoce, utilizând valori cut-off standard, s-au evaluat pe baza unei abordări probabilistice complexe corelațiile PCT cu factorii de risc materni, neonatali, semnele clinice şi semnele paraclinice ale nou-născuților din cele două loturi. A fost evaluată prevalența factorilor de risc privind cele două loturi analizate: lot I reprezentând nou-născuți cu infecție dovedită ce prezentau semne şi simptome clinice plus culturi pozitive şi lot II ce a inclus nou-născuți cu infecție suspectată ce prezentau semne şi simptome clinice, culturi negative, dar cel puțin două teste screening pozitive (CRP, HLG sau Rx).

Dintre factorii de risc implicați în infecția nou-născutului, cei ce prezintă o frecvență semnificativ mai mare la nou-născutul cu infecție dovedită sunt: MR >18h (p=0,043), colonizare cu streptococ de grup B (p=0,003), toți factorii de risc neonatali (VG, greutate mică la naştere), detresa respiratorie (p=0,0008), distensia abdominală (p=0,0042), edemul şi scleredemul (p<<0,05) şi EUN (p<<0,05).

În acest studiu un nivel seric al PCT≥0,5ng/mL a fost acceptat ca fiind patologic.

În loturile de studiu PCT pozitivă (>0,5 ng/mL) s-a asociat semnificativ (r=0,85, p=0,01) cu prezența infecției dovedite (hemocultură pozitivă). La nou-născuții ce prezentau hemoculturi pozitive s-au regăsit 87,5% valori ale PCT>0,5ng/mL, în timp ce nou-născuții la care culturile au fost negative doar 11.02% prezentau valori ale PCT>0,5ng/mL (tab. II, III).

Suspiciunea prematurului pentru infecție a fost demonstrată de faptul că frecvența nou-născuților prematuri cu infecție dovedită şi procalcitonină pozitivă (81,25%) este semnificativ mai mare (r=0,88, p=0,0012, χ^2=10,15, 95%CI) comparativ cu frecvența nou-născuților la termen cu infecție suspectată şi procalcitonină pozitivă (0,79%) (tab. IV). Valorile mari ale procalcitoninei la nou-născutul prematur demonstrează riscul prematurului pentru infecție datorită imaturității imunologice şi factorilor de risc.

Pentru a evidenția utilitatea procalcitoninei şi corelarea acesteia cu factorii de risc implicați în apariția infecției neonatale, s-au evaluat rezultatele corelației multiple, avându-se în vedere modificările valorilor procalcitoninei în funcție de factorii de risc.

Tabelul conține factorii de risc predictivi pentru valorile procalcitoninei în ordinea importanței lor. Pe baza rezultatelor se poate aprecia faptul că EUN (r=0,74, p=0,0001), prezența edemelor (r=0,79, p=0,0004) şi scleredemelor (r=0,69, p=0,0025), vârsta de gestație (r=0,66, p=0,0018), valorile crescute ale CRP (r=0,67, p=0,0144), MR>18h (r=0,65, p=0,028), prezența leucocitozei (r=0,62, p=0,032) şi greutatea mică la naştere (r=0,61, p=0,035) sunt factori de risc semnificativi predictivi pentru valorile pozitive ale procalcitoninei (tab. V). Rezultatele analizei multivariate sunt prezentate sugestiv în graficul următor (fig. 1).

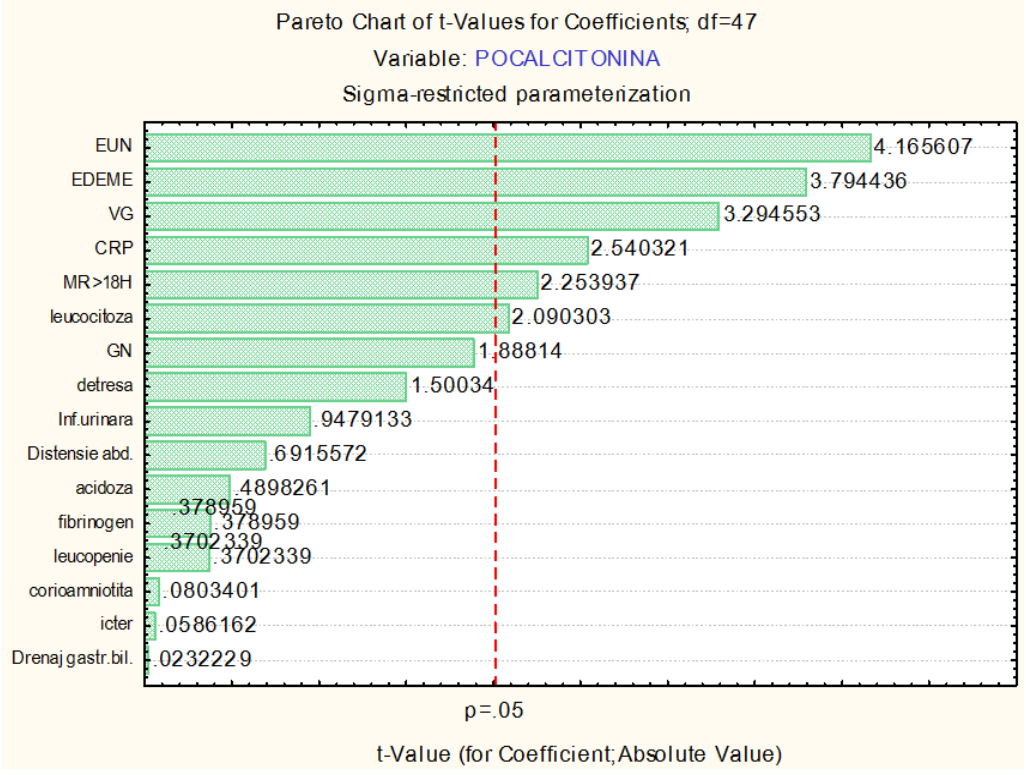

Fig. 1. *Valoare absolută a statisticii "t" în evaluarea analizei multivariate*

Corelarea multiplă a demonstrat că valori ale procalcitoninei peste 2 ng/ml s-au asociat cu infecția cu punct de plecare digestiv (EUN), cu semnele cutanate de suspiciune de infecție (edeme, scleredeme) cu vârsta de gestație mică, cu CRP, MR>18h, leucocitoză, ceea ce demonstrează utilitatea determinării procalcitoninei ca test rapid pentru evaluarea riscului de infecției şi ulterior urmărirea tratamentului.

TABELUL VI

Asocierea PCT pozitive vs. valori CRP

	CRP pozitiv (>8mg/L)		CRP negativ (<8mg/L)		Total
	Nr. cazuri	%	Nr. cazuri	%	
PCT pozitiv (>0.5ng/ml)	35	85,37%	19	16,10%	**54**
PCT negativ (<0.5ng/ml)	6	14,63%	99	83,90%	**105**
Total			**159**		

Nivelul seric al procalcitoninei la nou-născuții cu CRP pozitiv a fost peste 0.5 ng/ml în 85,37% din cazuri, iar la nou-născuții cu CRP negativ a fost de 16,1% (tab. VI). Asocierea între valorile pozitive ale CRP şi valorile pozitive al PCT este semnificativă (r=0,87, p<<0,05, 95%CI). De asemenea, se remarcă faptul că nivelul PCT creşte mai rapid în infecția neonatală decât nivelul CRP (r=0,56, p=0,0067, 95% CI) (fig. 2).

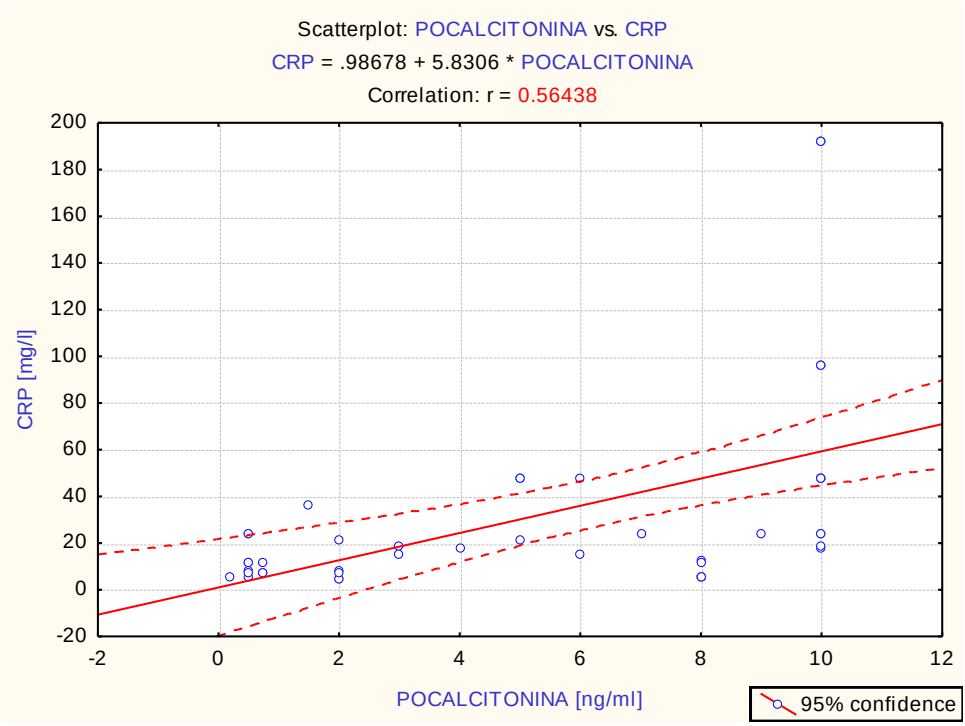

Fig. 2. *Dreapta de regresie PCT vs. CRP*

Utilizând hemocultura ca metodă gold standard, s-au calculat sensibilitatea, specificitatea, valorile predictiv pozitive şi predictiv negative şi acurateţea nivelului PCT pentru infecţia neonatală. Astfel, sensibilitatea şi specificitatea mare a procalcitoninei (specificitate=88,98%, sensibilitate=87,5%) demonstrează că acurateţea determinării procalcitoninei în loturile de studiu a fost de 88,68% în intervalul 24-72 ore de viaţă.

CONCLUZII

Nivelurile serice crescute ale PCT în loturile studiate pledează pentru utilizarea PCT în stabilirea rapidă şi precoce a diagnosticului de suspiciune şi sepsis neonatal.

În cazurile cu PCT pozitive şi hemoculturi (-) sau CRP (+) şi semne clinice de infecţie PCT poate fi un test util în iniţierea sau întreruperea antibioterapiei, ceea ce ar duce la scăderea costurilor.

Utilizarea PCT ca şi test screening la cazurile cu risc de infecţie, datorită costului ridicat al investigaţiei necesită studii privind raportul cost/beneficiu şi implicaţiile pe termen lung ale sepsisului nou-născuţilor şi al antibioterapiei.

EPIDEMIOLOGICAL OBSERVATIONS ON SURVIVAL IN THE FIRST YEAR AFTER ACUTE ST-ELEVATION MYOCARDIAL INFARCTION (STEMI) TREATED BY PRIMARY ANGIOPLASTY (Abstract): Conditional analysis of survival factors after acute myocardial infarction is important in care practice. We analyzed the survival and occurrence of coronary ischemic events during the first year after the episode of acute myocardial infarction with ST segment elevation (STEMI). We prospectively evaluated at one month and one year the patients with STEMI assisted in November 2008 - February 2010 at Heart Institute "Niculae Stăncioiu" with primary coronary angioplasty (ACP) performed during the first 12 hours of the onset of pain. We analyzed statistically survival and occurrence of ischemic events. Survival rate was 95.6% (CI95%: 92.7 to 97.3) at one month and 92.1% (CI95%: 87.8 to 94.2) ate one year after STEMI. Survival was significantly reduced in anterior STEMI (83.4%), history of ischemic heart disease (83.4%), stroke (81.2%), females (81.8%) and ischemia exceeding > 6 hours (83.6%). The rate of ischemic events avoidance was 96.5% (CI95%: 0.938 to 0.980) at one month and 81.7% (CI95%: 76.7 to 85.6) at one year after STEMI. The ischemic events, as evaluated through avoidance rate of phenomena, were significantly more frequent in females (69.9%), dyslipidemic (72.9%), hypertensive (73.7%) patients, having history of ischemic heart disease (72.4%) and total ischemia time longer than 6 hours (70%). Evolution of patients with STEMI after ACP is significantly better in patients with non-anterior location, males, without history of coronary disease, stroke, hypertension, dyslipidemia, ischemic time > 6 hours. **Keywords**: STEMI, PRIMARY CORONARY ANGIOPLASTY, SURVIVAL.

Bolile cardiovasculare cauzează peste 12 milioane de decese anual în lume (raportul OMS 1991-93), iar boala cardiacă ischemică reprezintă principala cauză de deces la adult. Peste 25% din decesele de cauză cardiovasculară se datorează infarctului miocardic acut (IMA), dar cifrele pot subestima realitatea (1). Supravieţuirea după un episod de IMA şi evenimentele apărute post-STEMI reprezintă o preocupare permanentă a cardiologilor. Cunoscând factorii care pot influenţa evoluţia acestor pacienţi şi acţionând în consecinţă, se poate îmbunătăţi prognosticul.

Fatalitatea în prima lună după un infarct miocardic acut este de aproximativ 50%,

dintre care aproximativ 50% se produc în primele 2 ore (1). Mortalitatea înaltă prespitalicească din primele ore nu a suferit modificări importante în ultimii ani. Mortalitatea intraspitalicească avea incidenţă de aproximativ 16% în era pre-reperfuzie, dar mortalitatea la o lună s-a redus la 4-6% după introducerea terapiei cu fibrinolitice şi a intervenţiilor coronariene percutane (2).

Trialurile randomizate efectuate în ultimii 20 de ani pe pacienţi cu STEMI, mortalitate pe termen scurt (la 30 de zile de la debut) cu o tendinţă de evoluţie încurajatoare: aproximativ 6-7% (trialul GUSTO-I raportează mortalitate la 30 de zile post-STEMI de 6,9%) (3). În schimb, mortalitatea raportată de registrele STEMI variază între 15-20%. Rezultatele trialurilor nu pot fi aplicate în practica clinică la aproximativ 50% din pacienţi, deoarece pacienţii incluşi în studiile randomizate sunt selectaţi, fiind la risc mai mic decât cei din practica de zi cu zi (4, 5).

Puţinele date existente referitoare la mortalitatea prin IMA în România arată că ţara noastră se situează printre ţările cu cea mai ridicată fatalitate prin IMA din Europa, STEMI fiind o problemă majoră de sănătate comunitară.(4, 6, 7, 8, 9)

Tratamentul STEMI urmăreşte restabilirea promptă şi cât mai completă a fluxului coronar prin una din cele două metode de reperfuzie disponibile: angioplastia primară, respectiv trombofibrinoliza (10). Succesul terapeutic depinde de timpul total de ischemie (timpul de la debutul durerii toracice până la momentul revascularizaţiei, TTI), deoarece unica variabilă asupra căreia se mai poate acţiona în evoluţia pacienţilor cu STEMI (IMA cu supradenivelare de segment ST) este timpul (11, 12, 13, 14). Factorii de risc ai cardiopatiei ischemice şi unele boli coexistente pot influenţa supravieţuirea acestor pacienţi şi frecvenţa evenimentelor post-STEMI.

Scopul lucrării a fost analizarea supravieţuirii şi a evenimentelor medicale coronariene apărute în primul an după episodul acut de STEMI la pacienţii trataţi de urgenţă prin angioplastie coronariana primară percutanată.

MATERIAL ŞI METODĂ

Am analizat supravieţuirea şi evenimentele coronariene care apar în primul an după angioplastia primară transcutanată la pacienţii cu IMA cu supradenivelare de segment ST (STEMI) prin supravegherea prospectivă a cazurilor.

Criteriile de includere a cazurilor au fost: asistarea la camera de urgenţă a Institutului Inimii din Cluj-Napoca, însoţită de terapia de reperfuzie miocardică prin angioplastie primară în primele 12 ore de la debutul durerii precordiale, capacitatea pacientului sau a aparţinătorilor de a da relaţii despre episodul actual de STEMI, acceptul de participare la studiu. Nu au fost incluşi: pacienţii de la care nu s-au putut culege informaţii despre evenimentele petrecute între debutul durerii şi internarea în secţia specializată, cei care au refuzat participarea la studiu şi pacienţii cu infarct miocardic sechelar.

Eşantionul a fost format din cazurile care au corespuns criteriilor de includere stabilite, care s-au prezentat în serviciul de urgenţă al Institutului Inimii „Niculaie Stăncioiu” în perioada noiembrie 2008 – februarie 2010. Fiecărui caz selectat i s-a completat o fişă de culegere de date, de concepţie originală, în care s-au înregistrat: datele personale, antecedente personale patologice (prezenţa unor factori de risc coronarian: statusul de fumător, prezenţa în antecedente a diagnosticelor de hipertensi-

une arterială, diabet zaharat, dislipidemie, accident vascular cerebral sau cardiopatie ischemică), date privind internarea, date diagnostice, durata asistenţei în alte servicii medicale anterior internării, date privind intervenţia de reperfuzie.

Pentru realizarea supravegherii prospective, tuturor pacienţilor li s-a solicitat prezentarea în serviciul de cardiologie pentru reevaluare la 30 de zile şi la 12 luni după episodul acut. Datele culese la reevaluare au fost înregistrate în acelaşi formular de supraveghere, incluzând relaţii despre angorul recurent, reinternările pentru angor, reinfarctizarea, insuficienţa cardiacă gravă sau decesul. Culegerea tuturor datelor necesare s-a încheiat în februarie 2011.

Baza de date pentru analizarea evoluţiei în primul an după STEMI, a fost realizată în programul informatic Excel, iar prelucrarea statistică în *Epi Info*.

Analiza statistică a urmărit rata de supravieţuire a pacienţilor, rata de apariţie a evenimentelor ischemice cardiace şi relaţia acestora cu factorii de risc urmăriţi, precum şi timpul total de ischemie. În prelucrarea statistică a parametrilor de studiu s-a folosit metoda Kaplan Meier, metoda actuarială şi metoda Log Rank pentru analizele comparative.

REZULTATE

În perioada noiembrie 2008 – februarie 2010, pe baza criteriilor de selectare stabilite, au fost incluşi în studiu 321 de pacienţi cu STEMI. Pacienţii au avut vârsta medie de 59,9 ani (între 24 şi 88 ani), 67,6% (IC95%: 62,1-72,6; p<0,001) au provenit din mediul urban, 73,8% din cazuri (IC95%: 68.6-78.5; p<0,001) au fost de gen masculin; sunt caracteristici semnificative statistic ţinând cont de structura populaţiei din regiune (14).

În prima lună după STEMI, în eşantionul studiat au apărut 14 decese, corespunzător unei rate de supravieţuire de 95,6% (IC95%: 92,7-97,3) (tab. I). La un an de la STEMI, rata de supravieţuire a fost de 92,1% (IC95%: 87,8-94,2), în total înregistrându-se un număr de 24 de decese. Pe parcursul studiului 58 de pacienţi (17,5%) au fost pierduţi din supraveghere.

TABELUL I

Ratele de supravieţuire la o lună şi la un an după infarctul miocardic acut.

Interval de timp (zile)	Vi	Di	Li	Ni	S(ti+1/ti)	S(ti+1)	IC
[0, 30]	321	14	0	321	0,956	0,956	0,927-0,973
[31, 365]	307	10	58	278	0,964	0,921	0,878-0,942

Vi :numărul de subiecţi vii la începutul intervalului; Di: numărul de subiecţi decedaţi în intervalul de timp; Li: numărul de subiecţi vi la ultimele noutăţi, la care timpul de participare se opreşte în intervalul de timp stabilit; Ni: numărul de subiecţi la risc; S(ti+1/ti): rata supravieţuire la finele intervalului; S(ti+1): rata cumulată de supravieţuire; IC: intervale de încredere.

Evenimentele ischemice sub formă de angor recurent şi reinfarctizare au fost evitate cu o rată cumulativă de 96,5% (IC95%: 93,8-98) în prima lună de evoluţie după STEMI şi de 81,9% (IC95%: 76,7-85,6) în primul an după STEMI (tab. II).

TABELUL II

Ratele de apariţie a evenimentelor ischemice coronariene la o lună şi la un an după infarctul miocardic acut.

Interval de timp (zile)	FIi	ISCHi	Li	Ni	S(ti+1/ti)	S(ti+1)	IC
[0, 30]	321	11	0	321	0,965	0,965	0,938-0,980
[31, 365]	310	43	58	281	0,846	0,817	0,767-0,856

FIi: numărul de subiecţi la care s-a montat stent şi sunt fără fenomen ischemic la începutul intervalului; ISCHi: numărul de subiecţi care au prezentat un fenomen ischemic în intervalul de timp; Li: numărul de subiecţi fără fenomen ischemic la ultimul control, la care timpul de participare se opreşte în intervalul de timp stabilit; Ni: numărul de subiecţi la risc; S(ti+1/ti): rata de evitare a fenomenelor ischemice la finele intervalului; S(ti+1): rata cumulată de evitare a fenomenelor ischemice; IC: intervale de încredere.

Supravieţuirea la un an a fost semnificativ mai redusă la pacienţii cu infarct miocardic localizat anterior (rata de supravieţuire de 83,4% [75,6-89,1]; p: 0,011 < 0,05), la cei cu antecedente de cardiopatie ischemică (rata de supravieţuire 83,4% [75,4-89,2]; p: 0,003 < 0,05) sau accident vascular cerebral (rata de supravieţuire 81,2% [64,6-91,1]; p: 0,04 < 0,05), la pacienţii de gen feminin (rata de supravieţuire 81,8% [70,8-89,2]; p: 0,016 < 0,05) şi la cei la care timpul total de ischemie (TTI) a fost mai mare de 6 ore (rata de supravieţuire 83,6% [75,6-89,3] ; p: 0,009 < 0,05) (tab. III, fig. 1). Nu s-au identificat diferenţe semnificative ale supravieţuirii pacienţilor care prezentau diabet zaharat, hipertensiune arterială, dislipidemie, erau fumători şi cei care au provenit din mediul rural.

TABELUL III

Ratele de supravieţuire la un an după STEMI în funcţie de caracteristicile pacienţilor, de localizarea infarctului şi de durata de ischemie până la reperfuzare.

Caracteristici	Rata de supravieţuire la un an (%)	Intervale de încredere (95%)	Semnificaţia statistică (p)
IMA anterior	83,4	75,6-89,1	0,011 < 0,05
IMA nonanterior	94	88,9-96,8	
CI în antecedente	83,4	75,4-89,2	0,003 < 0,05
Fără CI în antecedente	93,7	88,8-96,5	
AVC în antecedente	81,2	64,6-91,1	0,04 < 0,05
Fără AVC în antecedente	90,6	86,2-93,7	
Gen feminin	81,8	70,8-89,2	0,016 < 0,05
Gen masculin	92	87,4-94,9	
TTI sub 6 ore	93,6	88,7-96,5	0,009 < 0,05
TTI peste 6 ore	83,6	75,6-89,3	

IMA: infarct miocardic acut; CI: cardiopatia ischemică; TTI: timp total de ischemie.

Fig. 1. Curbele de supravieţuire funcţie de localizarea infarctului (a), prezenţa cardiopatiei ischemice în antecedentele pacienţilor (b), prezenţa accidentului vascular cerebral în antecedentele pacienţilor (c), gen (d) şi timpul total de ischemie mai mare de 6 ore (e).

Evenimentele ischemice coronariene în primul an după infarctul miocardic au fost mai frecvente în mod semnificativ la pacienţii de gen feminin (rata de evitare a ischemiei la 69,6% [57,1-79,4].; p: 0,001< 0,05), la cei cu dislipidemie (rata de evitare a ischemiei la 72,9% [65,2-79,2]; p: 0,008 < 0,05), cu hipertensiune arterială (rata de evitare a ischemiei la 73,7% [66,7-79,6]; p: 0,018 < 0,05), cu antecedente de cardiopatie ischemică (rata de evitare a ischemiei la 72,4% [63,1-79,9]; p: 0,03 < 0,05) şi la cei la care TTI a fost mai mare de 6 ore (rata de evitare a ischemiei la 70% [60,5-77,7]; p: 0,003 < 0,05) (tab. IV, fig. 2). Frecvenţa evenimentelor ischemice coronariene nu a fost diferită la pacienţii cu infarct miocardic localizat anterior, la cei care prezentau diabet zaharat, cei care aveau accident vascular cerebral în antecedente, erau fumători şi cei care au provenit din mediul rural.

TABELUL IV

Ratele de evitare a evenimentelor ischemice în primul an după STEMI în funcţie de caracteristicile pacienţilor şi de durata de ischemie până la reperfuzare.

Caracteristici	Rata de evitare a evenimentelor ischemice la un an (%)	Intervale de încredere (95%)	Semnificaţia statistică (p)
Gen feminin	69,6	57,1-79,4	0,001
Gen masculin	82,1	76,2-86,8	(< 0,05)
Dislipidemie în antecedente	72,9	65,2-79,2	0,008
Fără dislipidemie	87,6	80-92,4	(< 0,05)
HTA în antecedente	73,7	66,7-79,6	0,018
Fără HTA în antecedente	89,8	81,6-94,5	(< 0,05)
CI în antecedente	72,4	63,1-79,9	0,03
Fără CI în antecedente	83,6	76,9-88,5	(< 0,05)
TTI sub 6 ore	85,4	78,9-90,1	0,003
TTI peste 6 ore	70	60,5-77,7	(< 0,05)

HTA: hipertensiune arterială; CI: cardiopatia ischemică; TTI: timp total de ischemie.

Fig. 2. Curbele de supravieţuire privind apariţia unui eveniment ischemic coronarian funcţie de gen (a), dislipidemie (b), hipertensiune arterială (c), cardiopatia ischemică în antecedentele pacienţilor (d) şi timpul total de ischemie (e).

DISCUŢII

Mortalitatea în prima lună post-STEMI la lotul studiat este de 4,4%, ceea ce corespunde cu datele statistice publicate in literatura de specialitate: trialul GUSTO-I raportează mortalitate la 30 de zile post-STEMI de 6,9%. Mortalitatea la un an post-STEMI al eşantionului studiat este de 7,9%, cifră care de asemenea se plasează în marja de 5-10% publicată în literatură (3).

Trei din cele zece variabile urmărite au influenţat statistic semnificativ atât supravieţuirea până la deces, cât şi până la evenimentele urmărite în primul an post-STEMI: genul feminin, TTI peste 6 ore, respectiv prezenţa diagnosticului de CI în antecedentele pacientului. TTI mai lung presupune o pierdere mai mare de miocard viabil (13, 14, 16). Diagnosticul de CI în antecedente presupune o evoluţie mai prelungită a bolii cardiace ischemice, cu afectare coronariană mai extinsă.

IMA de perete anterior ventricular stâng (VS) este considerat mai grav ca evoluţie deoarece scoate din funcţie o cantitate mai mare de miocard şi predispune mai des la

dezvoltarea de anevrism VS (5, 11, 16).

Genul feminin influenţează negativ evoluţia pacienţilor post-STEMI, cunoscându-se faptul ca femeile dezvoltă mai rar IMA, dar prezintă forme mai grave (17, 18).

AVC antecedent la un pacient care suferă un STEMI presupune existenţa unei afectări vasculare cu localizări multiple, fiind deci un bolnav cu ateroscleroză difuză, ceea ce explică evoluţia lor grevată de complicaţii.

Contrar aşteptărilor, DZ şi fumatul nu au influenţat semnificativ rata apariţiei evenimentelor ischemice cardiace la pacienţii din prezentul studiu. Această constatare se poate datora faptului că s-au luat în studiu doar pacienţii cu STEMI care au fost asistaţi în timp util de la debutul simptomelor (sub 12 ore). Se cunoaşte că bolnavii cu DZ prezintă mai des forme oligo- sau chiar asimptomatice de IMA, ceea ce contribuie la întârzierea apelării la un serviciu specializat (19, 20) Tot aceasta ar explica şi numărul mai mic de diabetici cu STEMI incluşi în studiu.

Evenimentele ischemice în primul an post-STEMI, înregistrate în special la persoane de gen masculin, cu dislipidemii şi hipertensiune arterială, sunt factori de risc independenţi pentru cardiopatia ischemică. Prezenţa lor determină evoluţia bolii de bază (ateroscleroza coronariană), explicând totodată apariţia evenimentelor coronariene post-STEMI urmărite in studiu şi prognosticul mai rezervat al acestor pacienţi.

Limitele studiului realizat rezultă din culegerea anamnestică a datelor legate de timpul de ischemie şi de componentele acestuia, de la pacienţi sau aparţinători ai acestora, deci pot conţine inexactităţi asociate impactului psihologic aferent evenimentului acut de STEMI. De asemenea, în cadrul reevaluărilor, datele culese (adeseori telefonic) despre eventuala prezenţă a insuficienţei cardiace grave, aprecierea dispneei (subiectivă pe baza relatărilor pacientului), pot fi surse de bias.

CONCLUZII

Supravieţuirea în primul an post-STEMI tratat prin angioplastie primară este influenţată semnificativ de localizarea STEMI pe peretele anterior al VS, apartenenţa la genul feminin, TTI mai mare de 6 ore, prezenţa diagnosticului de cardiopatie ischemică sau accident vascular cerebral în antecedente. Implicit aceste caracteristici sunt factori de risc pentru decesul prin STEMI.

Evenimentele ischemice post-STEMI sunt influenţate negativ semnificativ de genul feminin, TTI peste 6 ore, prezenţa hipertensiunii arteriale, a dislipidemiei şi cardiopatiei ischemice în antecedentele pacienţilor. Aceşti factori pot fi consideraţi factori de prognostic negativ în evoluţia pacienţilor cu STEMI.

Educarea pacienţilor coronarieni şi informarea explicită a populaţiei generale privind importanţa vitală a recunoaşterii simptomelor precoce ale IMA şi a solicitării consultului medical precoce sunt esenţiale pentru ameliorarea prognosticului imediat şi de durată în STEMI.

THE PLATYSMA MYOCUTANEOUS FLAP (PMF) FOR RECONSTRUCTION OF DEFECTS AFTER EXTENDED PAROTIDECTOMY (Abstract). In order to reestablish the facial symmetry after the tumor removal, we can use sternocleidomastoid muscle transposition, dermis-fat graft, superficial musculoaponeurotic system (SMAS) plication, temporoparietal fascia flaps, microvascular free flaps and the platysma muscle flap. The technic depends on the size of the defect. MATERIAL AND METHODS. In this study we present our results of using a superiorly based platysma myocutaneous flap for reconstruction of defects after extended parotidectomy. The patients were treated for malign tumor of parotid gland which invaded the skin. RESULTS. All flaps were readily harvested at the time of tumor resection. Only two patients presented venous congestion. No flap was lost. There was no morbidity of donor site. The cosmetic outcome was satisfactory. DISCUSSION. The platysma myocutaneous flap is an alternative to more complex reconstructive technics, such as free flap transfer, and gives a satisfactory cosmetic result. CONCLUSIONS. The platysma myocutaneous flap is easy to harvest and has low donor site morbidity. The main disadvantage is represented by the vascularity problems. KEYWORDS. PAROTIDECTOMY, PLATYSMA, FLAP, RECONSTRUCTION.

Prima parotidectomie a fost raportată de către Bernard în 1823. De atunci au apărut numeroase modificări ale tehnicilor de îndepărtare a tumorilor parotidiene, de la simpla enucleere până la parotidectomia totală, cu sacrificarea sau prezervarea nervului facial (1). Parotidectomia este realizată pentru afecțiuni benigne, maligne primare sau secundare ale glandei parotide. Variantele de tratament chirurgical includ parotidectomia superficială, totală sau radicală, în funcție de tipul histopatologic şi extensia tumorii (2). Complicațiile postoperatorii cele mai frecvente sunt: pareza de facial, modificarea conturului feței, Sindromul Frey, tulburări de sensibilitate ale lobului urechii, hematoamele, sialocelele şi infecția plăgii (3, 4). Îndepărtarea unei tumori maligne de glandă parotidă implică uneori rezecții ample cu pierderi importante de substanță, însoțite de sacrificarea nervului facial, care determină tulburări funcționale şi cosmetice semnificative (5). Nitzan (6) a propus un chestionar adresat pacienților cu tumori benigne şi maligne în care erau evaluate postoperator durerea,

modificarea fizionomiei şi sindromul Frey. Dintre aceştia 58% s-au plâns asupra anomaliilor de contur facial.

Parotidectomia superficială sau totală, care nu este urmată de reconstrucție, determină o înfundare a regiunii preauriculare şi retromandibulare. De aceea, pentru a reface simetria facială sunt folosite mai multe tehnici de plastie: lamboul muscular din sternocleidomastoidian (7), din muşchiul digastric (8), sistemul musculoaponevrotic superficial (SMAS) (3), grefa de grăsime autologă (9), grefă din *fascia lata* (10), lamboul fascial temporoparietal (11), lambou liber parascapular deepitelizat (12), lambou musculocutanat paltisma (13) şi plasarea de implante sintetice (14). Pentru defectele mari, consecință a parotidectomiilor extinse, pierderea conturului facial necesită tehnici reconstructive complexe care să refacă estetica pacienților şi care, tot odată, să reducă la maximum complicațiile radioterapiei.

Transferul liber de țesuturi în reconstrucția defectelor extinse parotidiene, mastoidiene şi a tegumentelor adiacente (15) este din ce în ce mai folosit. Unii autori recomandă utilizarea lambourilor microvasculare şi în plastia defectelor parotidiene mai puțin extinse (16, 17).

Un interes deosebit îl poate prezenta şi folosirea lamboului musculocutanat platisma în reconstrucția defectelor postparotidectomie extinsă.

MATERIAL ŞI METODĂ

În prezentul studiu am inclus un număr de 6 pacienți care au fost operați în perioada 2006 – 2010 în Clinica de Chirurgie Orală şi Maxilofacială Iaşi pentru tumori maligne parotidiene şi la care reconstrucția s-a efectuat cu lambou musculocutanat platisma. Raportul bărbați/femei a fost de 5/1, cu vârste cuprinse între 59 şi 70 ani. În 4 cazuri examenul anatomopatologic a evidențiat carcinom scuamocelular, iar în două situații a fost carcinom adenoid chistic. La toți bolnavii s-a practicat parotidectomie totală extinsă cu îndepărtarea tegumentului invadat de tumoră, iar în 4 cazuri şi a unei părți din urechea externă (fig. 1), cu sacrificarea nervului facial infiltrat integral sau parțial.

Fig. 1. Pacient cu carcinom scuamocelular parotida stângă cu paralizie facial şi invazia lobului urechii şi a regiunii parotidiene

La fiecare pacient a fost efectuată şi evidarea ganglionară laterocervicală ipsilaterală modificată. Nici un bolnav nu a urmat radioterapie pre sau postoperatorie. Pentru reconstrucție s-a utilizat lamboul musulocutanat platisma pediculat cu pedicul superior.

REZULTATE

Toate lambourile au fost recoltate în momentul curei chirurgicale, iar evidarea ganglionară efectuată a fost uşurată deoarece, după ridicarea lambourilor regiunii cervicale grupurile ganglionare au fost

expuse larg, nemaifiind nevoie de incizii suplimentare.

Imediat postoperator 2 lambouri au prezentat congestie venoasă care s-a remis în 72 de ore. Un singur caz a avut necroză marginală de sub un cm pentru care s-a efectuat debridare şi cicatrizare secundară, cu efecte cosmetice satisfăcătoare. Nici un pacient nu a avut necroză totală a lamboului, iar rezultatul estetic a fost mulţumitor. Nu a existat morbiditatea zonei donatoare la nici un bolnav (fig. 2,3).

Fig. 2. Aspect postoperator cu paralizia nervului facial.

Fig. 3. Absența morbidității zonei donatoare şi a necrozei marginale.

Doi pacienţi au prezentat lagoftalmie paralitică şi nu au urmat tratament chirugical pentru corectarea acesteia prin implantarea unei plăcuțe din aur în pleoapa superioară ori prin blefarorafie definitivă datorită refuzului şi slabei cooperări ale acestora. Au preferat metodele conservative de tratament simptomatic, protector, care a constat în umezirea corneei şi protejarea acesteia de traumatismele locale. Bolnavii au folosit în acest scop lacrimi artificiale şi unguente oftalmice.

DISCUȚII

Parotidectomia extinsă determină alterări semnificative ale esteticii faciale. Calea de abord şi planul de tratament vor ține cont următorii factori: de localizarea, extensia şi tipul histopatologic al tumorii (18). În trecut, când o leziune malignă invada zone greu accesibile, precum fosa infratemporală sau baza craniului, acestea erau declarate inoperabile din cauza abordului dificil, a riscului hemoragic crescut şi a rezultatelor estetice şi funcționale slabe (18). În aceste cazuri, analiza preoperatorie a datelor obținute prin CT şi RMN creează o imagine tridimensională a poziției, volumului şi gradului de extensie al tumorii.

În cazul tumorilor extinse poate fi necesară excizia conductului auditiv, rezecție de os temporal, ram ascendent al mandibulei şi îndepărtarea tegumentelor infiltrate tumoral. Dacă se ia decizia sacrificării nervului facial, iar reconstrucția cu grefon nervos nu este fezabilă, trebuiesc luate măsuri de reabilitare a paraliziei de facial cât mai repede posibil.

În cazul parotidectomiei totale sau radicale, tehnicile locoregionale de reconstrucție şi refacere a simetriei faciale au anumite limitări. Plastia cu mușchi sternocleidomastoidian sau platisma creşte incidența leziu-

nilor nervoase, mai ales a marelui nerv auricular, şi determină înfundarea regiunii de unde a fost recoltat (3). Lamboul fascial temporoparietal şi transpoziția SMAS-ului sunt utile pentru plastiile după parotidectomii superficiale, dar nu conferă volum suficient necesar umplerii defectelor consecutive parotidectomiilor totale (19). Grefele grăsoase şi dermogrăsoase autologe pot restabili conturul facial (20), dar au dezavantajul resorbției variabile în timp, cu asimetrie consecutivă.

O altă tehnică pentru a restabili atât conturul facial cât şi funcția, este reprezentat de transferul liber de muşchi gracilis sau de lambouri libere microneurovasculare.

O alternativă viabilă şi relativ uşor de folosit o reprezintă lamboul musculocutanat paltisma. A fost descris pentru prima dată în 1887 de către Robert Gersuny pentru plastia unui defect al obrazului posttraumatic. Totuşi, abia în 1978 a fost descris de Futrell (21) pentru reconstrucția după carcinoame intraorale. Ulterior, în 1999, Kim (13) a folosit acest lambou pentru repararea defectelor postparotidectomie. Lamboul platisma mai poate fi utilizat pentru plastia defectelor cutanate, sau musculocutanate, din jumătatea inferioară a feței, de la nivelul gâtului şi cavității orale. Versatilitatea acestuia l-au mai recomandat în repararea stricturilor benigne de hipofaringe, refacerea bărbiei şi a buzelor, reconstrucția traheei la pacienții cu neoplasm esofagian, replantări de ureche, plastia defectelor cutanate din regiunile parotidiană, mastoidiană şi geniană (22).

Vascularizația lamboului provine din ramul submental din artera facială, din artera tiroidiană superioară, artera occipitală şi auriculară posterioară (23). Vena jugulară externă şi vena submentală asigură drenajul venos, care are o orientare predominat pe verticală spre deosebire de vascularizația arterială multiaxială (24).

Lamboul musculocutanat paltisma poate fi cu pedicul superior, posterior sau inferior. Primele două oferă suficient țesut pentru repararea defectelor mici şi medii cu localizare cutanată sau intraorală. Ultimul pedicul are vascularizația din artera tiroidiană superioară, astfel că nu are aplicație în plastia orală sau facială (25).

Lambou musculocutanat platisma cu pedicul superior are avantajul că este uşor de recoltat, fără a necesita incizii suplimentare dacă s-a efectuat şi evidare ganglionară, are textură similară cu tegumentul regiunii primitoare, iar zona donatoare are morbiditate redusă (22, 26). Un alt avantaj este că asigură a protecție adecvată în cazul refacerii continuității nervului facial cu un grefon nervos.

Principalul dezavantaj este dat de problemele de vascularizație. Atât aportul arterial, cât şi drenajul venos pot fi compromise în momentul recoltării lamboului, în urma radioterapiei preoperatorii, sau în cazul evidărilor ganglionare sau a inciziilor cervicale preexistente (27). Unii autori au raportat tulburări ale vascularizației şi în cazul chimioterapiei neoadjuvante (28). Lamboul cu pedicul superior are o vascularizație foarte bună asigurată de arterele facială şi submentală, în schimb drenajul venos este mai puțin eficient şi se realizează prin venele comunicante anterioare în vena jugulară anterioară, tiroidiană superioară sau în vena facială (29). Lamboul cu pedicul posterior are un drenaj venos bun prin vena jugulară externă, dar vascularizația arterială este la întâmplare din artera occipitală (29).

Nu sunt de neglijat nici problemele oncologice şi limitările evidării ganglionare

date de necesitatea păstrării unei vascularizații decente a lamboului. În general, adesea, jugulara externă nu poate fi păstrată, de unde şi cea mai importantă complicație reprezentată de congestia venoasă a lamboului. Alte complicații sunt necroza parțială sau totală şi dehiscența plăgii.

CONCLUZII

Lamboul musculocutanat platisma este o metodă viabilă şi uşor de folosit pentru reconstrucția defectelor după parotidectomia extinsă cu pierdere cutanată. Pentru defectele voluminoase, care includ şi alte structuri în afara glandei şi tegumentelor, sunt recomandate lambourile liber transferate.

Lamboul musculocutanat platisma are textură asemănătoare cu a zonei acceptoare.

Morbiditatea zonei donatoare este minimă.

Prin facilitarea evidării ganglionare, timpul necesar recoltării lamboului este compensat. Durata redusă şi simplitatea tehnicii reprezintă argumente importante pentru utilizarea ei în cazul unor pacienți cu stare generală afectată de vârstă, afecțiuni concomitente ori stadiul bolii.

Principalul dezavantaj îl reprezintă problemele de vascularizație, dar şi posibilitatea limitată de refacere a conturului şi simetriei faciale.

TOXICOLOGIC SCREENING OF SOME SURFACTANTS USING MODERN *IN VIVO* BIOASSAYS (Abstract): This paper aims to evaluate the degree of skin irritation using specific *in vivo* tests. The completion of the study is to develop models with wide applicability in toxicological area. HET-CAM or chorioallantoic membrane assay is a new method accepted as an INVITTOX protocol that is a substitute of Draize test. The methods applied in present study were CAM assay on embryonated egg and CD1 Nu/Nu experimental model. The evaluation of erythema that is an important toxic effect of surfactants was done using a Mexameter MX18 (Courage Khazaka research line). The main observations were that sodium lauryl sulphate is the most toxic compound on our series but the non-ionic surfactants are not completely non-noxious. Non-invasive methods can be associated with other test such as CAM assay to evaluate irritant compounds. **Key words:** HET-CAM BIOASSAY, IRRITATION SCORE, DERMAL IRRITATION, SURFACTANT

The main goal of toxicological scientific endeavours is to safeguard human beings against the possible adverse effects of diverse types of chemicals, including pharmaceuticals, cosmetics and, of course, tensioactive compounds with a known noxiousness. The exposure can be incidental, accidental or intentional, even when the noxious tested formulation is a cosmetic or a drug. One of the most common effects of the exposition and accidental contact with a new chemical is eye and skin irritation evaluated by Draize test. Generally, the physiological response to a chemical stimulus is irritation, which involves objective changes (e.g., local redness and oedema) and subjective sensations (e.g., pruritus and pain) and these aspects could characterize noxious ingredients also and could be evaluated by scores (1). Even today, the final preclinical safety assessment of chemicals is largely based on animal experiments. However, ethical concerns involving the use of laboratory animals, the validity of animal eye and skin as human eye and skin models and the need for more efficient and cost-effective preclinical validation methods have promoted the development of alternative methods to assess irritation that will substitute the classical ones (1).

Surfactants, due to their surface or interface activities and physico-chemical properties, are among the most used excipients in cosmetic and pharmaceutical products for cleaning or other properties or for realising the forms. The application of the preparations containing these compounds may result in eye and skin irritation or other side reactions and important noxious consequences (2). As a consequence, it is of great interest to identify surfactants with low irritant

properties and, during this screening process, it is also necessary to have rapid assays to assess noxiousness and deep damaging effects. The evaluation of the irritant potential of chemicals *in vivo* is traditionally conducted in animals, particularly in rabbits (the Draize test method), rodents or other tests (3, 4, 5, 6). However, due to increasing concern over animal use and obvious ethical implications of using directly human subjects, *in vitro* alternative methods should now be encouraged and they are enough developed (5). Different *in vitro* approaches have been proposed for assessing eye irritation as an alternative to the Draize eye irritation test, including the use of cultured cells, isolated organs or fertilized hen eggs (6).

The mechanism by which surfactants cause skin irritation is not fully understood. Series of factors contributing to their irritation potential include : (a) direct action on the *stratum corneum* components (lipids and proteins), (b) interaction with living epidermal cells altering their proliferative capacity and (c) action on dermal components inducing mediator release and inflammation. No single *in vitro* model and no single assay will be able to mimic all the events that occur *in vivo* in the human skin, thus, a complex of methods are required to conclude about the surfactants toxicity and to offer a detailed evaluation (7).

The chorioallantoic membrane (CAM) is the vascularised respiratory membrane that surrounds a chick developing inside an egg. There are several variations in CAM assay protocols. One of the scores determines the irritation potential from a formula which includes the time in seconds at which haemorrhage, vasoconstriction and coagulation appear and it is useful to prove also the antiangiogenic effect of antitumoral compounds. The irritation potential ranges from 0 to 21 and the analysed substances will be included in this interval. This method allows different types of substances such as surfactants (8), cosmetics, ingredients (9), different chemical products (10,11,12) or dental adhesives (13) to be evaluated as irritant and noxious ingredients.

The Cosmetic Toiletry and Fragrance Association performed an evaluation of alternatives to the Draize primary eye irritation test because of a lot of things (ethical, details of mechanism, etc). They concluded that none of the assays exhibited 100% sensitivity and 100% specificity. However, the CAM method achieved 94% sensitivity and 100% specificity (14). The combination of histological and visual HETCAM tests is of interest, as it may give a more sensitive evaluation of the innocuousness of cosmetic active ingredients, easy to develop (15). The amount of stain fixed on the damaged membrane is quantified and evaluated (16,17). We have introduced a modification to the method, whereby the membrane weight is measured after dissection and the results are expressed as a function of the membrane weight (18).

Excessive exposure of skin to physical and environmental agents implicitly favours the appearance of photoaging. Interventions on the body skin through aggressive environmental factors such as formulations with surfactants are matters of concern to current research and to offer details about the application of alternative methods. These represent the arguments for our study.

MATERIALS AND METHODS

Sodium lauryl sulphate (SDS or SLS), Tween 20 and Tween 60 solutions were in concentration 0.5%. They were offered by the UMFT Pharmaceutical Technology department. A vehicle control solution was prepared for the application on the CAM ; the pure reagent was diluted with distilled water (1 : 10, v/v).

SDS. SDS was administered onto the CAM as positive control using a solution 1mg/ml in distilled water.

HET CAM Assay

The bioassay is used to evaluate the potential ocular irritancy of any test substance as measured by its ability to induce toxicity at the vascular level of the chorioallantoic membrane of the chicken (19). The HET-CAM bioassay was performed following ICCVAM recommendations published in November 2006 in Appendix G and adapted to our laboratory conditions (20,21). In brief, fertilized eggs were horizontally incubated 7 day prior to use, at 37^0C, in controlled wet atmosphere. On the 3rd day of incubation, in order to detach the chorioallantoic membrane, 3 ml of albumen were aspired through a perforation at the more pointed end of the eggs. The hole was resealed and returned to the incubator. The next day, a big window was cut and resealed on the superior side of the shell. The eggs were returned to incubate until the 8th day. 5 eggs were used for each test substance. After inspecting and recording the surface of the CAM by means of a stereomicroscope, 0.3 ml of the control and test solution diluted in NaCl 0.9% were applied to the CAM. The reactions produced were observed over a period of 300 seconds. The time for the appearance of each selected endpoint was registered in seconds. The endpoints observed were : haemorrhage, H (bleeding from the vessels), vascular lysis, L (blood vessel disintegration), coagulation, C (intra- or extra- vascular protein denaturising). A variety of analysis methods may be used to assess irritancy potential of test substances. One analysis method that has been used extensively is an irritation score (IS). The formula used to generate an IS value is (22,23) :

$$IS = 5 \times \frac{301 - SecH}{300} + 7 \times \frac{301 - SecL}{300} + 9 \times \frac{301 - SecC}{300}$$

where : H = haemorrhage ; L = vessel lysis ; C = coagulation ; Sec = start second

Haemorrhage time (Sec H) = observed start (in seconds) of haemorrhage reactions on CAM, Lysis time (Sec L)= observed start (in seconds) of vessel lysis on CAM, Coagulation time (Sec C) = observed start (in seconds) of coagulation formation on CAM After the treatment time of 5 min, the main reaction was scored (either haemorrhage or lysis, or coagulation) according to the following scheme : 0 = no reaction ; 1 = slight reaction ; 2 = moderate reaction ; 3 = severe reaction. Mean scores were determined.

Animals and treatment

CD1 Nu/Nu mice were purchased from Charles River (Sulzfeld, Germany), 4 mice /group. From the week 8 the tested solution was applied on the dorsal area : group A. whitness-just solvent (water), group B SLS 5% solution, group C Tween 20 5% and group D Tween 60 5%, 2 times/day each. The final results were carted after 30 days. The work protocol followed all NIAH-National Institute of Animal Health rules : animals were maintained during the experiment in standard conditions : 12h light-dark cycle, food and water *ad libidum*, temperature 24°C, humidity above 55%.

The mexametric measurements were performed using a research device from Courage Khazaka, with a Mexameter MX18 (Courage &Khazaka Electronics, Cologne, Germany). The maximum units for Mexameter are 999 (interval 0-999) and the measurement is based on the absorption/reflexion. For the measurements, the mice were anesthetised with xylazine and ketamine. The time of measuring was continuous for 20 seconds. The protocol followed the observations on haemoglobin status (erythema). The device was applied on most obvious affected areas and maintained on the skin for 20 seconds. The data were registered by the specific soft from the Mexameter MX18 device and then expressed as units. All data were processed as initial and final measurements values on the same area.

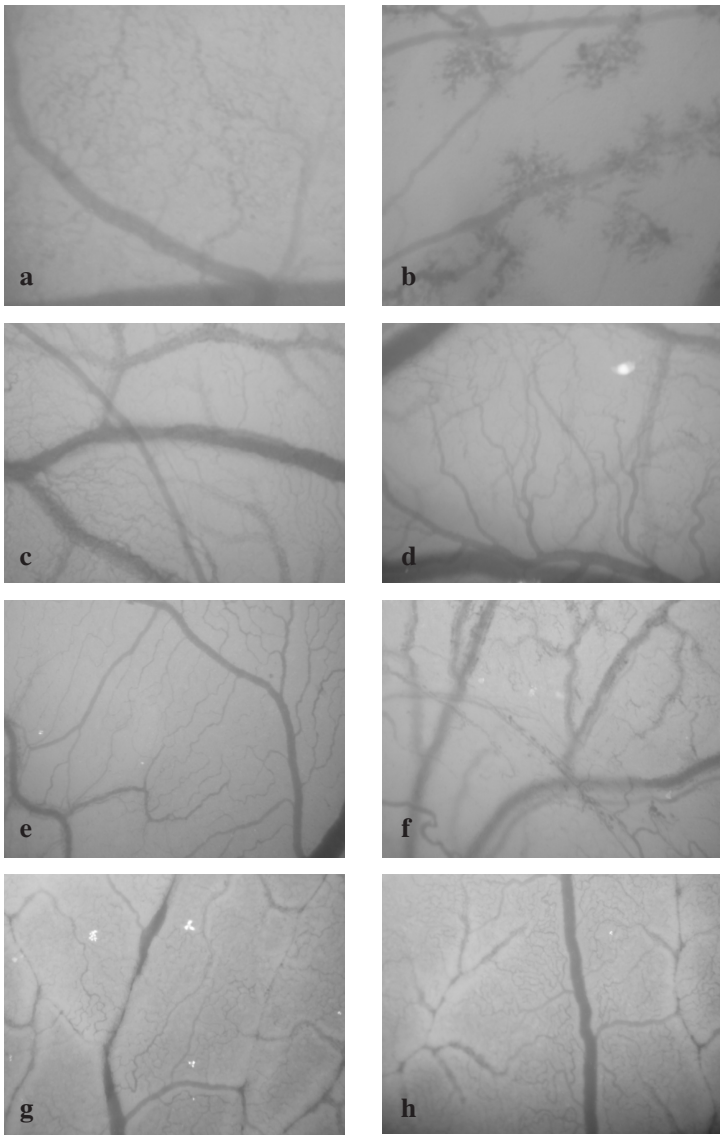

Fig. 1. HET CAM bioassay, en face images of chorioallantoic membrane before (left) and after 5 min of contact with the tested compounds (right), Stereomicroscope mycrographs x20 : a) SDS -before, b) SDS-after, c) Na Cl 0.9% -before, d) NaCl 0.9% - after, e) Tween 20 - berfore, f) Tween 20 - after, g) Tween 60 -before, h) Tween 60 - after

RESULTS AND DISCUSSIONS

The effects induced by the tested compounds as well as the selected controls were registered as microphotographs representing the en face surface of the chorioallantoic membranes before and after 5 min of substance contact (fig. 1).

Prior to the determination of irritation score, the results obtained for irritation thre-

TABLE I
Irritation score, severity and effect classification

Test compound and controls	Irritation score (mean)	Irritation severity (mean)	Classification of the effect
SDS (1 mg/mL) Positive control	17.99	3	Severe reaction
Na Cl 0.9% Negative, vehicle control	0	0	No reaction
Tween 20 (1 mg/mL)	5.43	1	Slight to moderate reaction
Tween 60 (1 mg/mL)	8.45	0.75	Slight reaction

shold was considered. The test chemical concentrations were selected based on the irritation threshold results. All the three end points, hemorrhage, coagulation and lysis were observed for SDS, Tween 20 and Tween 60 respectively. The mean irritation score for SDS is 17.99. The test showed 0 irritation score for solution of Na Cl 0.9% (tab. I; fig. 2).

The results show a great difference between the positive control, SDS and the two test surfactants Tween 20 and Tween 60. SDS induced major dammage at the vascular level of the chorioallantoic membrane; after the application of 0.3 mL of solution (1 mg/mL), a large area was affected by high number of mycrohemorrhages, the death of the specimen was registered after 20 min of contact with the solution. The other specimens had somehow a better viability, until the next day.

The two evaluated surfactants did not produce severe irritative reaction on the capillary plexus of the treated CAM. Both of them showed mycrocoagulation signs. Tween 20 expressed a more generalised and severe reaction , which emerged later, explaining in this way the lower value of the irritation score. Also there was no sign of lysis and the vasodilation and slight haemorragy came out only at the end of the observing time. In what concerns Tween 60, there were a few

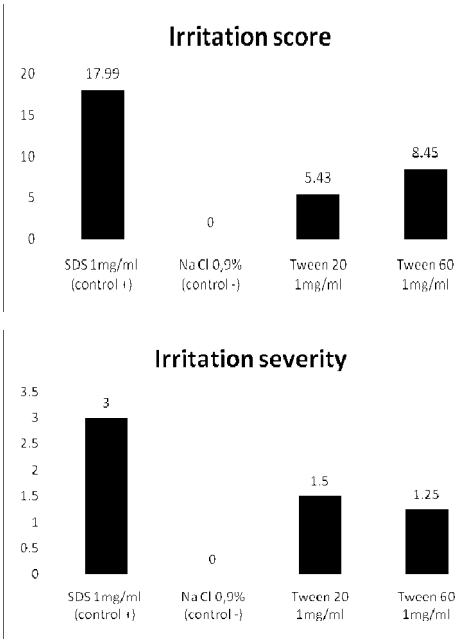

Fig. 2. Diagrams of the irritation score and its grade of severity for the tested surfactants and the control solutions

areas of mycrocoagulation and of vascular lysis, but which have been registered earlier, causing a higher irritation score, even if the severity of the reaction was classified as slight.

In vivo experiments sustain the theory of irritancy for tested compounds aspects ob-

A. Whitness B.Tween20 C.Tween60 D. SLS

Fig. 3. *In vivo* evaluation of surfactants solution observed on macroscopic images on CD1 Nu/Nu mice after 30 days of continuous application

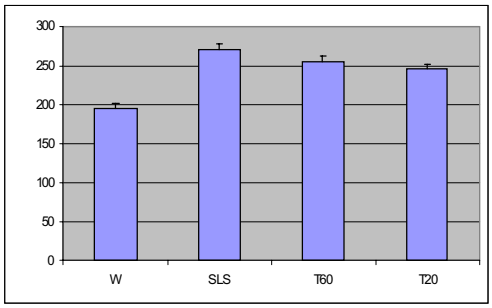

Fig. 4. Erythema units measured as comparative values at the end of experiment (day 30)

served on macroscopic images (fig. 3). The most irritative compound is the reference one SLS but also the nonionics (Tweens) developed dry skin and irritant reactions (fig. 3 and 4). The mexametric values of the erythema induced after the application of surfactants are in correlation with the irritation score obtained after the HET-CAM evaluation. Considering these results, Tween 20 showed the lowest irritative potential comparing to Tween 60, which induced a more severe reaction and to SDS, which is the positive control for toxic effects. The irritation severity can be considered a more subjective parameter, while the irritation score has a better prediction capacity.

Surfactants, due to their surface and interface activities, are among the most common and versatile components of pharmaceutical and cosmetic preparations, cleansers, soaps and shampoos with an intense usage. Thus, the concentrations used in commercial formulations should avoid adverse reactions such as skin irritation and other damages. For this reason, the search for new non-irritative surfactants has generated considerable interest, although pre formulation developmental trials are needed (24). Furthermore, there is a pressing need to develop biodegradable and biocompatible surfactants with low toxicity and excellent emulsifying properties, particularly in light of increasing concerns about energy consumption and environmental and toxicological dangers (25, 26). Our study underline the noxious potential of tensioactive compounds using as reference SLS, a well known irritant. Neither the Tweens are without signs of noxious effects if they are tested as single compounds. Future studies will evaluate the formulations with combinations of surfactants or with compounds that can lead to macromiceles formation to evaluate the differences.

HET-CAM was proposed to mimic the effects that may occur in the conjunctiva following exposure to a test substance. Chicken embryo models have long been used by embryo toxicologists (27,28,29) and our evaluations proved its applicability. Extending the use of chicken embryos, the HET-CAM test was proposed by Luepke as an alternative in vitro method.

Studies also have suggested that the extra embryonal vascular systems (yolk sac, CAM)

are not sensitive to pain. These studies suggest that on day 9 of incubation, there is no pain perceived by the developing embryo during the HET-CAM test (20).

In the present study, a good correlation was found between the HET-CAM test results and reported data from others irritation tests. Non-invasive methods such as mexametric measurements can be applicable to evaluate irritation potential and to confirm noxiousness evaluated by other methods.

CONCLUSIONS

In summary, according to the presented *in vivo* tests, surfactants non-ionic compounds developed a lower irritation potential than the well known SLS even on CAM assay and in *vivo*-erythema measurement tests.

A large number of studies have been undertaken to find tests that replace the need for animals in eye and skin safety testing and it seems that it is adequate. The tests on mouse skin that is a fidel test on a total body can be correlated with CAM assay. A battery of tests should be established as no single assay can fulfill the requirements for risk assessment using an *in vitro* method and part of these tests could be the simple tests on embryonated eggs or measurements on animals skin with non-invasive techniques.

INFLUENCE OF FINISHING TECHNIQUES ON THE SURFACE ROUGHNESS OF METALLIC COMPONENTS OF PROSTHETIC RESTORATIONS (Abstract): The paper proposes to examine the influence of mechanical and electrolytic finishing techniques on metal surface roughness. **Material and method**: Six non-noble dental alloys and three versions of finishing have been taken into consideration: mechanical polishing with rubber polisher, mechanical polishing with cotton polisher and abrasive paste and electrolytic polishing. Examinations on roughness have made reference to R_z, R_a and R_q. **Results**: The experimental results obtained have shown that mechanical polishing with rubber polisher is recommended for Co-Cr-Mo alloys, while mechanical polishing with cotton polisher and abrasive paste or electrolytic polishing are suited for Ni-Cr alloys. **Conclusion**: Analysis of values obtained led to formulation of recommendations concerning the best polishing method for each non-noble alloy considered. **Key words**: NON-NOBLE DENTAL ALLOYS, POLISHING TECHNIQUES, ROUGHNESS R_Z, R_A, R_Q

Componentele metalice ale restaurărilor protetice sunt supuse operaţiei de lustruire care are ca scop îmbunătăţirea calităţii de suprafaţă, prin micşorarea considerabilă a rugozităţii stratului superficial (1).

Rugozitatea unei suprafeţe este o abatere a profilului real de la forma profilului ideal şi ea este reprezentată prin: striaţii şi rizuri periodice sau pseudoperiodice, smulgeri de material, urme lăsate de scule şi goluri aperiodice.

Descrierea matematică a profilului microneregularităţilor se poate face cu ajutorul unor mărimi simplificatoare: R_z – rugozitatea medie a suprafeţei; R_a – abaterea medie aritmetică a profilului; R_q – abaterea medie pătratică a profilului (2).

SCOPUL STUDIULUI

Studiul şi-a propus efectuarea unei analize comparative privind influenţa tehnicilor de finisare asupra rugozităţii suprafeţei componentelor metalice ale restaurărilor protetice realizate din diferite aliaje nenobile.

Presupunând existenţa unei dependenţe între rugozitatea suprafeţelor metalice şi procesul de dezvoltare a plăcii bacteriene, această analiză va permite identificarea ulterioară a corelaţiei dintre tehnicile de finisare, rugozitatea suprafeţei şi integrarea biologică (3).

MATERIALE ŞI METODĂ

Cercetările experimentale au fost efectuate pe şase aliaje nenobile (4) cu utilizare frecventă în protetica dentară (tab. I).

Pe epruvete cilindrice (φ7 x 10 mm) realizate din aceste aliaje, a fost executată o faţetă plană (l=3 mm) la nivelul căreia s-au efectuat, în trei zone ale aceleiaşi direcţii longitudinale, măsurători ale rugozităţii.

Tehnicile de finisare aplicate la nivelul

faţetei au fost : lustruirea mecanică - pentru toate aliajele şi lustruirea electrolitică - specifică numai aliajelor Co-Cr-Mo şi Ni-Cr.

Lustruirea mecanică a fost realizată cu un micromotor Schick C3 Master, utilizând discuri gumate abrazive sau pufuri din bumbac şi paste abrazive speciale.

Pentru lustruirea electrolitică, probele au fost imersate într-o soluţie acidă, tensiunea aplicată între electrozi fiind U = 12 Vcc, iar durata procesului t = 15 min.

REZULTATE

Măsurătorile de rugozitate au fost realizate pe un echipament special Mitutoyo SJ-301 (Japonia), pe fiecare epruvetă fiind efectuate trei determinări la nivelul aceleiaşi direcţii, după care s-a calculat valoarea medie a fiecărui parametru.

Soft-ul rugozimetrului (5) a permis trasarea profilului microneregularităţilor (fig. 2, 3 şi 4) şi determinarea tuturor mărimilor simplificatoare (tab. II, III şi IV).

DISCUŢII

Valorile medii ale parametrilor de rugozitate (R_z, R_a şi R_q) determinate prin măsurătorile efectuate pe suprafaţa plană a epruvetelor din aliajele nenobile dentare studiate sunt reprezentate grafic în fig. 5, 6 şi 7.

Analizând comparativ rezultatele prezentate în tab. II, III, IV, se pot face următoarele discuţii referitoare la valorile celor trei mărimi simplificatoare specifice rugozităţii.

- Rugozitatea medie (R_z) a suprafeţelor plane lustruite mecanic şi electrolitic
  - după lustruirea mecanică cu disc gumat abraziv cele mai mici valori s-au obţinut la aliajele Co-Cr-Mo, valori medii pentru aliajele Ni-Cr şi cele mai mari pentru aliajele de bază de titan (tab. II) ; dispersia valorilor este largă, deoarece : R_z (Robur 400) = 57,57% · R_z (Biotan) ;
  - valorile cele mai mici pentru (R_z) după lustruirea mecanică cu puf şi pastă abrazivă, sunt obţinute la aliajele Ni-Cr, valori medii pentru aliajele Co-Cr-Mo şi cele mai mari pentru aliajele pe bază de titan ; dispersia valorilor este mai restrânsă, deoarece : R_z (Kera N) = 44,57% · R_z (Biotan-Nb) ;
  - lustruirea electrolitică conduce la obţinerea unor valori cu dispersie mare atât între aliajele din aceeaşi grupă, cât şi

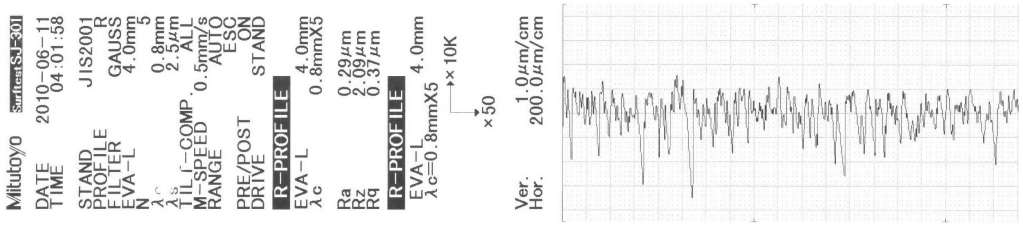

Fig. 2. Profilul microneregularităţilor pentru epruvete din aliaje nenobile lustruite mecanic cu disc gumat abraziv

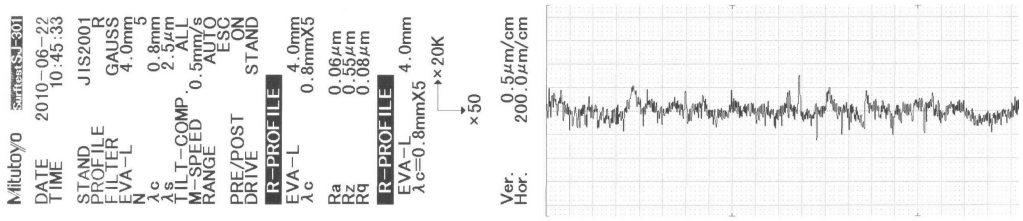

Fig. 3. Profilul microneregularităţilor pentru epruvete din aliaje nenobile lustruite mecanic cu puf şi pastă abrazivă

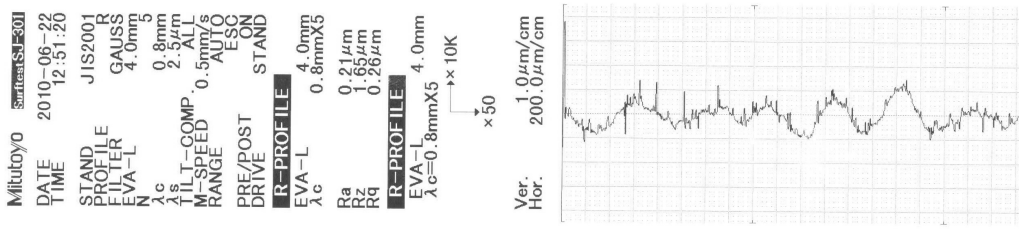

Fig. 4. Profilul microneregularităţilor pentru epruvete din aliaje nenobile lustruite electrolitic

TABELUL II

Valorile medii ale parametrilor de rugozitate (R_z, R_a şi R_q), pentru suprafeţele metalice lustruite mecanic cu disc gumat abraziv şi cu puf şi pastă abrazivă

Nr. crt.	Aliaje nenobile	Marca aliajului	Valori medii după lustruirea cu disc gumat abraziv, [μm]			Valori medii după lustruirea cu puf şi pastă abrazivă, [μm]		
			R_z	R_a	R_q	R_z	R_a	R_q
1	Aliaje Co-Cr-Mo	Sismo	1.817	0.246	0.330	0.617	0.067	0.093
2		Robur 400	1.686	0.220	0.287	0.603	0.067	0.090
3	Aliaje Ni-Cr	Kera N	2.097	0.293	0.377	0.536	0.057	0.073
4		Ugirex III	2.526	0.334	0.487	0.580	0.060	0.083
5	Aliaje pe bază de titan	Biotan	3.973	0.580	0.737	0.843	0.113	0.143
6		Biotan-Nb	2.833	0.480	0.590	0.967	0.120	0.160

între aliajele din grupe diferite. Astfel : R_z (Sismo) = 53,62% · R_z (Robur 400), iar R_z (Kera N) = 34,82% · R_z (Ugirex III), în timp ce R_z (Sismo) = 39,51% · R_z (Ugirex III).

- Abaterea medie aritmetică (R_a) a profilului microneregularităţilor suprafeţelor plane lustruite mecanic şi electrolitic

TABELUL III

Valorile medii ale parametrilor de rugozitate (R_z, R_a şi R_q), pentru suprafeţele metalice lustruite electrolitic

Nr. crt.	Aliaje nenobile	Marca aliajului	Valori medii după lustruirea electrolitică, [μm]		
			R_z	R_a	R_q
1	Aliaje Co-Cr-Mo	Sismo	2.506	0.203	0.310
2		Robur 400	3.247	0.304	0.453
3	Aliaje Ni-Cr	Kera N	2.700	0.210	0.325
4		Ugirex III	4.143	0.326	0.503

TABELUL IV

Dispersia valorilor parametrilor de rugozitate R_z, R_a şi R_q

Aliaje nenobile	Marca aliajului	Lustruire mecanică cu disc gumat abraziv			Lustruire mecanică cu puf şi pastă abrazivă			Lustruire electrolitică		
		R_z	R_a	R_q	R_z	R_a	R_q	R_z	R_a	R_q
Aliaje Co-Cr-Mo	Sismo							39.51	37.73	38.36
	Robur 400	57.57	62.07	61.05						
Aliaje Ni-Cr	Kera N				44.57	49.56	43.75			
	Ugirex III							100	100	100
Aliaje pe bază de Ti	Biotan	100	100	100	100	100	100	-	-	-
	Biotan-Nb							-	-	-

Notă: 100% - valoarea maximă a parametrului de rugozitate; x%: - valoarea minimă a parametrului de rugozitate.

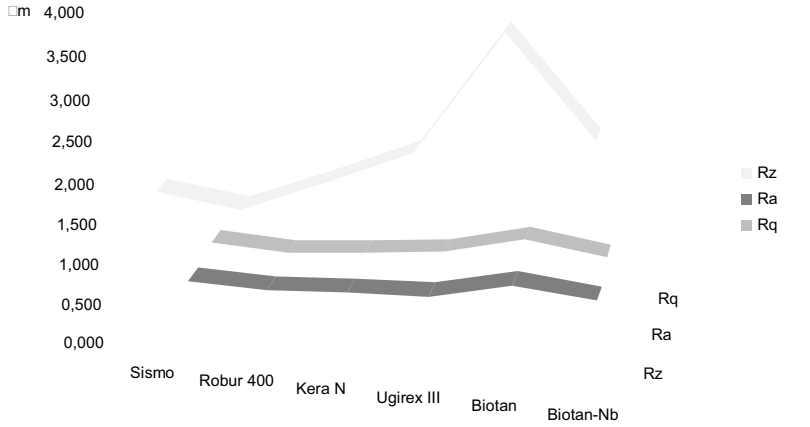

Fig. 5. Variaţia valorilor medii ale parametrilor de rugozitate (R_z, R_a şi R_q) pentru epruvetele lustruite mecanic cu disc gumat abraziv

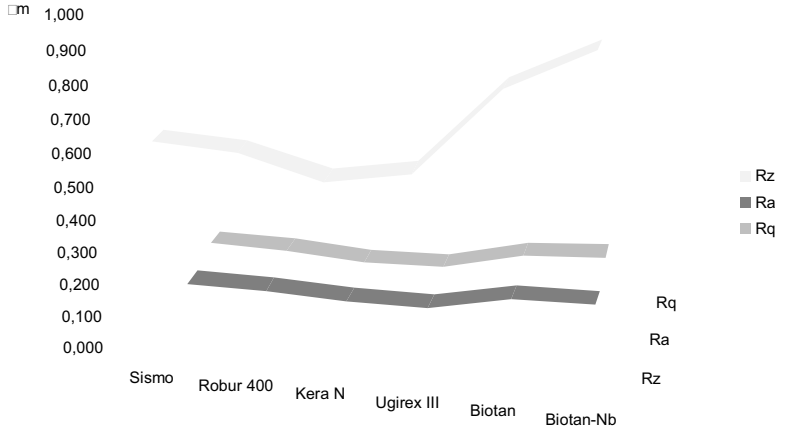

Fig. 6. Variaţia valorilor medii ale parametrilor de rugozitate (R_z, R_a şi R_q) pentru epruvetele lustruite mecanic cu cu puf şi pastă abrazivă

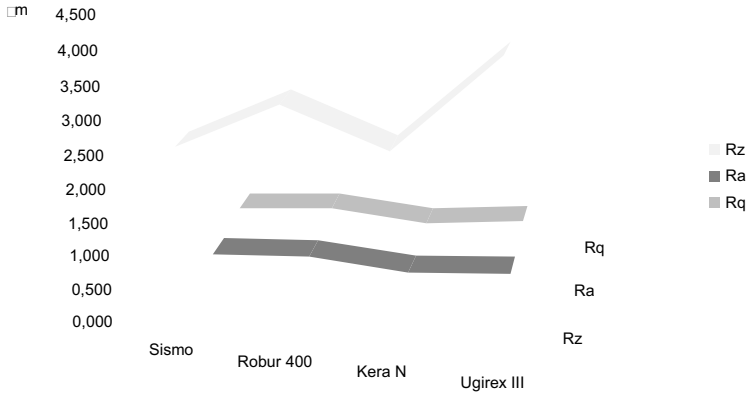

Fig. 7. Variaţia valorilor medii ale parametrilor de rugozitate (R_z, R_a şi R_q) pentru epruvetele lustruite electrolitic

– după lustruirea mecanică cu disc gumat abraziv, cele mai mici valori s-au obţinut la aliajele Co-Cr-Mo, valori medii pentru aliajele Ni-Cr şi cele mai mari pentru aliajele pe bază de titan; dispersia rezultatelor este largă, deoarece: R_a (Kera N) = 62,07% · R_a (Biotan);

– valorile cele mai mici pentru (R_a) după lustruirea mecanică cu puf şi pastă abrazivă, sunt obţinute la aliajele Ni-Cr, valori medii pentru aliajele Co-Cr-Mo şi cele mai mari pentru aliajele pe bază de titan; dispersia rezultatelor este mai restrânsă, deoarece: R_a (Kera N) = 49,56%

$\cdot R_a$ (Biotan);
- după lustruirea electrolitică, se obţine o dispersie mică a valorilor între aliajele Co-Cr-Mo şi Ni-Cr, iar R_a (Sismo) = 37,73% $\cdot R_a$ (Ugirex III).

• Abaterea medie pătratică (R_q) a profilului microneregularităţilor suprafeţelor plane lustruite mecanic şi electrolitic
- după lustruirea mecanică cu disc gumat abraziv, cele mai mici valori s-au obţinut la aliajele Co-Cr-Mo, valori medii pentru aliajele Ni-Cr şi cele mai mari pentru aliajele pe bază de titan; dispersia rezultatelor este largă, deoarece: R_q (Robur 400) = 61,05% $\cdot R_q$ (Biotan);
- valorile cele mai mici pentru (R_q) după lustruirea mecanică cu puf şi pastă abrazivă, sunt obţinute la aliajele Ni-Cr, valori medii pentru aliajele Co-Cr-Mo şi cele mai mari pentru aliajele pe bază de titan; dispersia rezultatelor este mai restrânsă deoarece: R_q (Kera N) = 43,75% $\cdot R_q$ (Biotan);
- după lustruirea electrolitică se menţine o dispersie considerabilă a valorilor specifice între aliajele Co-Cr-Mo şi Ni-Cr, când R_q (Sismo) = 38,36% $\cdot R_q$ (Ugirex III).

CONCLUZII

Pe baza rezultatelor obţinute prin măsurători ale rugozităţii efectuate pe aceeaşi direcţie longitudinală a unei suprafeţe plane, se pot formula unele concluzii generale:
- au fost studiate şase mărci de aliaje aparţinând la trei clase de aliaje nenobile, cu utilizare frecventă în protetica dentară;
- probele prelevate din fiecare aliaj au fost lustruite prin trei tehnici: lustruire mecanică cu disc gumat abraziv, lustruire mecanică cu puf şi pastă abrazivă şi lustruire electrolitică;
- rugozitatea suprafeţei lustruite a fost evaluată prin trei mărimi simplificatoare specifice: R_z, R_a şi R_q;
- analiza valorilor medii determinate evidenţiază aspecte tehnice importante:

• pentru toate aliajele, cea mai mică rugozitate se obţine după lustruire mecanică cu puf şi pastă abrazivă, iar cea mai mare rezultă după lustruirea electrolitică;
• lustruirea mecanică cu disc gumat abraziv şi cea electrolitică sunt recomandate aliajelor Co-Cr-Mo;
• lustruire mecanică cu puf şi pastă abrazivă este destinată aliajelor Ni-Cr şi celor pe bază de titan.

- diferenţele remarcabile dintre valorile rugozităţii obţinute prin lustruirea mecanică şi cea electrolitică pot fi explicate prin natura mecanismelor specifice celor două procese: deformarea plastică prin fluaj a microneregularităţilor profilului – pentru lustruirea mecanică cu puf şi pastă abrazivă, respectiv descompunerea anodică a vârfurilor microneregularităţilor – pentru lustruirea electrolitică;
- se constată că alunecarea datorată fluajului va asigura un grad de netezire a suprafeţei superior, comparativ cu cel rezultat prin descompunerea anodică.

TUBERCULOSIS PREVALENCE IN MURES COUNTY IN 2006-2008 (Abstract): The aim of this study is analysis of tuberculosis prevalence in Mures county for a period of three years (2006-2008). **Material and method**: We monitored the prevalence of tuberculosis cases in the Mureş area recorded at Tg. Mureş TB Dispensary, the new cases and readmitted cases, chronic or abandonment, separately for children and adults, evolving for 2006-2008, data compared with national registration. **Results**: From 2006 to 2008, frequency of TB illness in our area decreased instead of the share of patients with positive results (BK+) wich have increased, associated with an amplified risk. In our study the assessment during the three years showed a decrease of the total number of TB cases, instead of increased frequency of new cases of acute than those of chronic, increased cases of adults against children and cases of failed healing. Number of new cases of TB in Mureş urban areas, by years, showed the same decreasing trend for cities monitored, except Tg. Mureş where the number of new cases recorded in 2008 was higher than in 2006. **Conclusion**: TB control programs in order to be effective, must be conducted throughout the all country, to be permanent, to the satisfaction of the population and to integrated structure of community health. **Key words**: TUBERCULOSIS, RISK FACTORS, MANAGEMENT

În România, în ultima perioadă au fost raportate aproximativ 28.000 de cazuri noi de tuberculoză (TBC) şi recidive anual. Incidenţa globală a bolii a avut după anul 1985 o evoluţie constant ascendentă, ajungând în anul 2002 la valoarea maximă de 142,2%ooo. În anii următori s-a înregistrat o tendinţă de stabilizare şi chiar de uşoară scădere a valorilor acestui indicator. Cu toate acestea, în anul 2004 România se situa, pe locul 3 din 52 de ţări ale Regiunii Europa a OMS - după Federaţia Rusă (cu 121.426 de cazuri) şi Ukraina (cu 38.403 de cazuri) - iar ca incidenţă pe locul 42 din 211 ţări din întreaga lume şi pe locul 2 (după Kazakhstan) în Regiunea Europa a OMS (1,2). În perspectiva integrării în Uniunea Europeană, România se află cu siguranţă pe primul loc printre ţările UE atât ca număr de cazuri, cât şi ca incidenţă.

Analiza endemiei TBC din România arată că, spre deosebire de celelalte ţări europene, amploarea fenomenului nu se datorează nici migraţiei (în fiecare an sunt raportate doar câteva cazuri la persoane născute în afara ţării) şi nici infecţiei HIV (procentul infectaţilor HIV din numărul cazurilor de tuberculoză raportate a fost în ultimii ani sub

0,5%). Foarte probabil că un factor important al severităţii endemiei îl reprezintă problemele socio-economice grave cu care se confruntă ţara noastră. Scăderea nivelului de trai a influenţat cu certitudine evoluţia incidenţei, dovadă fiind şi faptul că incidenţa cea mai mare se înregistrează în judeţele din sudul ţării şi din Moldova, cele care au şi cele mai importante probleme socio-economice (3,4).

Factorii de risc de infecţie sunt determinaţi de cei de îmbolnăvire, astfel cel mai important determinant al instalării infecţiei la un contact cu un caz de tuberculoză activă este severitatea cazului din punct de vedere bacteriologic (infecţiozitatea sa). Urmează apoi condiţiile de expunere (volumul de aer respirat împreună cu sursa) : aglomerarea şi intimitatea surselor, timpul petrecut împreună. La acelaşi grad de infecţiozitate, aglomerare de persoane şi intimitate a contactului, stilul de viaţă al persoanelor devine un factor de risc de infecţie : igiena locuinţei şi igiena personală. (2)

Caracteristicile ultimei perioade de timp pe plan mondial dar şi naţional evidenţiază o modificare în distribuţia cazurilor, tuberculoza fiind net mai frecventă la grupele populaţionale ce prezintă anumite particularităţi. Aceste subgrupuri pot fi identificabile şi un sistem de supraveghere a tuberculozei trebuie să fie orientat în primul rând către cartografierea grupelor cu risc crescut, pentru orientarea adecvată a acţiunilor antituberculoase. Abilitatea de a identifica aceste grupuri şi locuri geografice particulare în care ele apar este însă afectată de acurateţea diagnosticului, de corectitudinea declarării cazurilor şi de colectarea corectă a datelor.

Obiectivul acestui studiu este de a analiza datele de prevalenţă ale tuberculozei la nivelul judeţului Mureş şi în ţară, pe o perioadă de 3 ani (2006-2008). Am comparat suplimentar aceste date judeţene cu cele naţionale, prin constituirea profilului naţional demografic de bază al pacienţilor cu tuberculoză.

MATERIAL ŞI METODĂ

Am monitorizat prevalenţa şi trendul cazurilor de tuberculoză din arealul judeţului Mureş înregistrate la Dispensarul TBC din Tg. Mureş, pe cazuri noi şi cazuri readmise, cele cronice sau de abandon, separat pentru copii şi adulţi, evolutiv pentru anii 2006-2008. Datele naţionale sunt înregistrate la Institutul Naţional de Pneumologie Marius Nasta din Bucureşti, prin raportări judeţene anuale.

REZULTATE

Prima parte a acestui studiu s-a concentrat pe detaliile privind incidenţa TBC în mediul urban mureşan completată de caracteristicile de monitorizare, în dinamică pe 2006-2008. Am urmărit comparativ, datele corespunzătoare principalelor oraşe din judeţ : Tg. Mureş, Reghin, Luduş, Sighişoara şi Târnăveni.

Per total, cele mai multe cazuri de TBC înregistrate, indiferent de ani sau categorie, au fost în Tg. Mureş (municipiul de judeţ), iar cele mai puţine în Luduş.

Din 2006 până în 2008, frecvenţa îmbolnăvirilor a scăzut de la 359 la 336 pentru Tg. Mureş, iar în total per judeţ de la 725 la 661. Deşi numărul de cazuri de TBC înregistrate în perioada 2006-2008, a scăzut, ponderea pacienţilor cu rezultate pozitive (BK+) a crescut de la 70,2% la 71,55%, cu un risc de gravitate amplificat (tab. I).

Cazurile noi de TBC au arătat aceeaşi scădere uşoară din 2006 faţă de 2008 (de la 534 de cazuri la 530), în schimb am observat o creştere a frecvenţei cazurilor acute din totalul celor monitorizate de la un an la altul (reprezentând 73,65% din pacienţii pe 2006, 78,92% din pacienţii pe 2007, respectiv 80,18% din pacienţii din 2008). Au fost asociate şi cu o creştere a frecvenţei cazurilor pozitive de la 63,1% la 66,22% (BK+) (tab. I).

Cazurile readmise de TBC au arătat o scădere din 2006 faţă de 2008 (de la 103 de cazuri la 93), asociate însă cu o creştere

TABELUL I

Situaţia statistică a cazurilor de tuberculoză înregistrate în judeţul Mureş (perioada 2006-2008), corespunzătoare pentru adulţi

mai uşoară a frecvenţei cazurilor pozitive de la 90% la 91,39% (BK+) (tab .I).

Pacienţii copii au avut o frecvenţă mai mică decât a adulţilor, de asemenea cu un trend în scădere din 2006 către 2008 (de la 57 la 38 de cazuri) şi frecvenţe apropiate de la un an la altul (cu o medie de 14%) (tab. I).

Cazurile de abandon sunt destul de puţine dar de interes curativ şi preventiv, de la 23 de abandonuri în monitorizare în 2006 la 15 cazuri în 2008, cu o medie anuală de 2,5% din pacienţii înregistraţi (tab. II).

Cazurile de eşec curativ sunt apropiate ca număr şi frecvenţă cu cele de abandon, 2,75% din totalul pacienţilor monitorizaţi, în scădere ca evoluţie pe parcursul perioadei studiate (de la 20 în 2006 la 14 în 2008) (tab. II).

La capitolul de cronici, ponderea este mai scăzută (5,65% din totalul pacienţilor), cu o scădere de la 41 de cazuri în 2006 la 7 în 2008, reducere semnificativă ($p < 0,004$) (tab. II).

Per total, în lotul nostru de evaluare, pe parcursul celor 3 ani de urmarire, a scăzut numărul de cazuri de TBC, în schimb a crescut frecvenţa cazurilor noi acute, faţă de cele cronice, au crescut cazurile de adulţi faţă de copii, precum şi situaţiile de eşec curativ.

Numărul cazurilor noi de TBC din judeţul Mureş, comparativ pe ani şi mediul urban au arătat acelaşi trend descrescător pentru toare oraşele monitorizate, cu excepţia municipiului Tg. Mureş unde numărul cazurilor noi înregistrate în 2008 a fost mai mare decât cel din 2006 (284 faţă de 271). Astfel, pe parcursul a 3 ani, aici a scăzut frecvenţa cazurilor totale de pacienţi cu TBC, pe fondul cazurilor de cronici, în schimb au crescut cazurile noi înregistrate (tab. I şi fig. 1).

Numărul cazurilor de TBC la copiii din judeţul nostru, comparativ pe ani şi mediu urban a demonstrat o evoluţie în scădere de la un an la altul, fără diferenţe semnificative de la un oraş la altul, excepţie făcând oraşul Târnăveni singurul la care a crescut simţitor numărul şi frecvenţa pacienţilor copii cu TBC din 2006 către 2008, cu un vârf de

TABELUL II

Situaţia statistică a cazurilor de tuberculoză din judeţul Mureş (2006-2008), corespunzătoare cazurilor de cronici, abandon şi eşec

frecvenţă de 13 cazuri corespunzător anului 2007, urmat de o scădere la 8 cazuri.

Numărul cazurilor de TBC la cronicii din judeţul Mureş, comparativ pe ani şi mediu urban a arătat de asemenea o scădere de la un an la altul, fără diferenţe semnificative de la un oraş la altul, cele mai multe cazuri fiind în Tg. Mureş iar cele mai puţine în Târnăveni aspect pozitiv ţinând cont că aceşti pacienţi au o colaborare mai dificilă şi o toleranţă mai scăzută la tratamentul complex care adesea durează 12-18 luni.

Evoluţia în dinamică a cazurilor de TBC din judeţul Mureş (2006-2008), arată o grafică similară pentru categoriile importante în evaluare (adulţii, copii, cronicii şi cazurile acute), cu menţiunea că cea mai mare frecvenţă o prezintă cazurile noi de TBC, iar cele mai mici sunt cazurile cronice şi de copii, din lotul întreg (fig. 2).

DISCUŢII

Am dorit compararea datelor judeţene mureşene cu cele naţionale, pentru aceeaşi perioadă de timp, prin constituirea profilului naţional demografic de bază al pacienţilor cu tuberculoză, analiza migraţiei acestora şi spitalizării pe anumite spitale sau zone geografice, precum şi respectarea recomandărilor Programului Naţional de Control al tuberculozei (4). Astfel, la nivel de ţară şi în Mureş, 85% dintre bolnavii de tuberculoză se internează în spitale din judeţul de domiciliu, această pondere fiind aproximativ aceeaşi cu cea pentru restul pacienţilor de pe alte secţii. Absenţa migraţiei inter-judeţene sugerează o acoperire suficientă cu servicii spitaliceşti specifice la nivelul fiecărui judeţ (5,6).

În această perioadă anuară, cea mai mare pondere a cazurilor de tuberculoză din totalul cazurilor spitalizate în ţară se constată în judeţul Giurgiu (3%), în restul judeţelor ponderea fiind sub 2%, respectiv judeţul Mureş fiind pe locul zece ca frecvenţă.

Proporţia mare a cazurilor de tubercu-

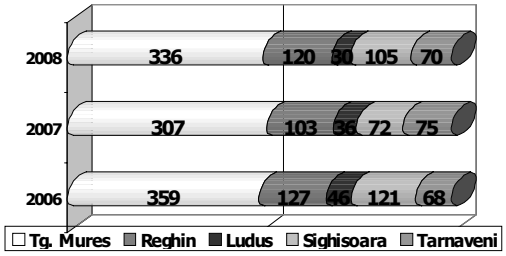

Fig. 1. Numărul total al cazurilor de TBC din judeţul Mureş, comparativ pe ani şi mediul urban

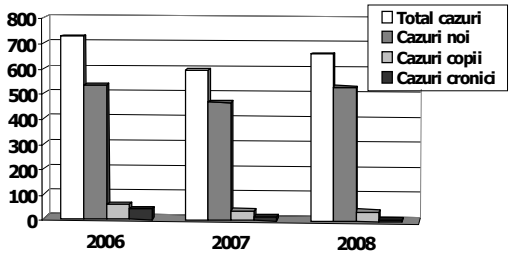

Fig. 2. Evoluţia în dinamică a cazurilor de TBC din judeţul Mureş (2006-2008)

loză este desigur specifică sanatoriilor TBC şi a spitalelor de pneumoftiziologie; proporţiile cele mai ridicate sunt deţinute de Spitalul de pneumoftiziologie Bixad şi Drajna.

În România, ca de altfel în întreaga lume, cazurile de îmbolnăvire la bărbaţi sunt de 2,1 ori mai frecvente decât cele la femei. Repartiţia pe grupe de vârste indică diferenţe între cele două sexe: cele mai multe îmbolnăviri apar la bărbaţi la vârste adulte, între 40 şi 54 de ani, iar la femei la vârste mai tinere, între 20 şi 34 de ani. Această observaţie conduce la concluzia că transmiterea infecţiei în populaţie nu este deocamdată pe deplin controlată (7,8). Aproape trei sferturi dintre cazurile de tuberculoză spitalizate în ţară sunt bărbaţi (72,6%), medie uşor mai crescută decât cea din Mureş (70,4%). Concentrarea cazurilor de TBC spitalizate se face la vârsta mijlocie (jumătate au vârsta între 40-60 ani).

Cea mai des întâlnită formă de tuberculoză este cea pulmonară (aproape 95%), cele mai frecvente cazuri (70%) fiind cele cu confirmare a diagnosticului prin examen microscopic al sputei şi cele cu investigaţii bacteriologice sau histologice negative.

Diagnosticul de tuberculoză este însoţit în jumătate de cazuri şi de comorbidităţi, cea mai frecventă fiind insuficienţa respiratorie cronică (3,89%), urmată de HTA esenţială (2,87%) şi BPOC (2,36%), asemănătoare cu datele mureşene (3,5).

Procedurile efectuate se rezumă, în general, la explorări funcţionale şi radiologice; radiografiile reprezintă mai mult de 10% din procedurile efectuate acestor pacienţi iar intervenţiile chirurgicale la bolnavii de TBC sunt rare (sub 1%).

Ponderea cazurilor fără asigurare la pacienţii cu tuberculoză este semnificativ mai mare comparativ cu ceilalţi pacienţi (13,83% faţă de 2,72%), în Mureş fiind de 10,7%.

Una din caracteristicile afecţiunii este perioada mare de spitalizare (38,59 zile), cu o medie de aproape 6 săptămâni în cazul tuberculozei faţă de o săptămână în cazul altor afecţiuni.

Tuberculoza nu este o boală înalt contagioasă. Dacă se ia în considerare infecţiozitatea pe unităţi de durată a expunerii, tuberculoza apare net mai puţin infecţioasă ca celelalte boli comunicabile ale copilului. Numai în circumstanţele ce permit un contact prelungit cu sursa eliminatorie de bacili (nedescoperirea la timp a cazurilor), în condiţiile unei aerisiri incorecte a încăperilor (condiţii de habitat deficitare) şi a unor concentraţii foarte mari în atmosfera respirată a particulelor infectante se poate ajunge la o rată mare de infecţie (9,10).

Factorii de risc de dezvoltare a unei boli active după o infecţie ţin în mare măsură de caracteristicile intrinseci ale indivizilor: vârstă, sex, conformaţie corporală (tip constituţional "ectomorfic" sau "liniar"), susceptibilitate genetică. În general, toate cauzele ce pot altera imunitatea mediată celular duc la un risc crescut de îmbolnăvire (11,12,13).

Totuşi, trebuie subliniat că vârsta este

un factor important pentru apariţia bolii, tuberculoza având o mare predilecţie pentru persoanele tinere. Faptul că tuberculoza boală apare astăzi îndeosebi la adulţi se datorează doar scăderii ratei infecţiei printre copii.

CONCLUZII

Din 2006 până în 2008, frecvenţa îmbolnăvirilor în arealul mureşan a scăzut, însă ponderea pacienţilor cu rezultate pozitive (BK+) a crescut, cu un risc de gravitate amplificat.

În lotul nostru de evaluare, pe parcursul celor 3 ani evolutiv, a scăzut numărul total de cazuri de TBC, în schimb a crescut frecvenţa cazurilor noi acute, faţă de cele cronice, au crescut cazurile de adulţi faţă de copii, precum şi situaţiile de eşec curativ.

Numărul cazurilor noi de TBC din judeţul Mureş, comparativ pe ani şi mediul urban au arătat acelaşi trend descrescător pentru toare oraşele monitorizate, cu excepţia municipiului Tg. Mureş unde numărul cazurilor noi înregistrate în 2008 a fost mai mare decât cel din 2006.

Aproape jumătate dintre cazurile de tuberculoză spitalizate au vârsta între 40 şi 60 de ani, respectiv trei sferturi dintre cazurile de tuberculoză spitalizate sunt bărbaţi

Diagnosticul de tuberculoză este însoţit în jumătate de cazuri şi de comorbidităţi, cea mai frecventă fiind insuficienta respiratorie cronică.

La peste jumătate dintre cazuri internarea se face prin trimitere de la medicul din ambulatoriu, iar durata medie de spitalizare este de 39 de zile.

Boală cu răspândire în masă, tuberculoza fiind o boală cu răspândire în masă, nu trebuie considerată numai ca boală a individului ci şi a comunităţii în care trăieşte acesta. Programele de combatere a tuberculozei, pentru a fi eficiente, trebuie să se realizeze pe întreg teritoriul ţării, să fie permanente, să răspundă cerinţelor populaţiei şi să fie integrate în structura sanitară a colectivităţii.

ASSOCIATED RISK FACTORS IN DEVELOPING ORAL MANIFESTATIONS IN PATIENTS WITH BLOOD DYSCRASIA (Abstract) : The oral and dental complications arising in cancer patients can be attributable to the malignant disease itself and to the various modalities of cancer therapy. Up to 37.2% of all patients receiving cancer chemotherapy develop acute oral complications and up to 31.1% of all patients receiving cancer radiotherapy develop acute oral manifestations. Oral complications may result in significant morbidity, impaired nutrition, treatment delays, and dose reductions which are affecting the prognosis of the primary disease. **Material and method** : We investigated 312 cases of blood dyscrasia which 296 cases had oral manifestations (86.2%). They had a mean age of 40,6 years (range from 7 to 86 years). The male to female ratio was 1.0 : 0.75 (178/134). Data were statistically analyzed by t test, chi-square, Wilcoxon, Kruskal-Wallis and two-tailed exact Fischer, using the *SPSS* program, at a significance level of 5%. **Results** : Oral complications are frequently encountered in patients receiving anticancer therapy and these complications may result in significant morbidity, treatment delays, dose reductions, and nutritional deficiencies. The acute effects of anticancer chemotherapy upon the oral cavity include mucositis, infection, hemorrhage, xerostomia and nutritional deficiencies. Patients which undergo radiotherapy, specific in head and neck carcinomas, display a 30-60% incidence of the oral manifestations. The antineoplastic therapy will interfere with the turnover of the epithelial cells, followed by mucosal injury, later by infections, due to indirect invasion of Gram-negative bacteria and fungal species, as most of the anti-cancer drugs cause immunological changes. **Conclusions** : The mucosal surface that is the oral cavity may provide insight into the immune function of the patient. Differential diagnosis is important as many disorders may manifest themselves similarly in the buccal area. **Key words** : ORAL MANIFESTATION, CANCER THERAPY, CHEMO-THERAPY, RADIATION, BLOOD DYSCRASIA

ANTIOXIDANT ACTIVITY OF ESSENTIAL OIL FROM *CARUM CARVI* L. CULTIVATED IN NORTH-EASTERN ROMANIA

ANTIOXIDANT ACTIVITY OF ESSENTIAL OIL FROM *CARUM CARVI* L. CULTIVATED IN NORTH-EASTERN ROMANIA (Abstract): Essential oils have significant antioxidant activity, being used frequently as preservatives in the food and cosmetic industries. **Aim**: To assess the *in vitro* antioxidant activity of essential oil from *Carum carvi* L. (caraway) cultivated in northeastern Romania. **Materials and Methods**: The essential oil was isolated by hydrodistillation from dried caraway fruits. The chemical composition was investigated by gas chromatography and gas chromatography–mass spectrometry analyses. Antioxidant activity was evaluated by three different *in vitro* antioxidant assays (DPPH· and $ABTS^{\bullet+}$ scavenging and reducing power assays). Butylhydroxyanisole was used as reference standard. **Results and Discussion**: Carvone was the major compound of essential oil of caraway fruits (48.53%), followed by limonene (44.42%). Evaluation of the antioxidant activity (DPPH·and $ABTS^{\bullet+}$ scavenging activity and reducing power) revealed significant effects, with IC_{50} values of 46.51 ± 1.61 µg/mL, 5.34 ± 0.07 µg/mL and 7.64 ± 0.22 µg/mL, respectively, as compared to those of the reference standard, butylhydroxyanisole (6.09 ± 0.27 µg/mL, 1.49 ± 0.00 µg/mL and 3.39 ± 0.07 µg/mL, respectively). **Conclusions**: Essential oil of *Carum carvi* cultivated in northeastern Romania belongs to carvone chemotype. Due to its high antioxidant activity it might be a potential alternative to conventional preservatives in the food, cosmetic and pharmaceutical industries. **Keywords:** *CARUM CARVI* L., CARVONE, ESSENTIAL OIL, ANTIOXIDANT ACTIVITY.

Medicinal plants are used for thousands of years due to their content in bioactive compounds, endowed with therapeutic and nutritional effects. Among these compounds, essential oils have been targeted for investigation with regard to their biological properties, especially concerning their antioxidant activity and their potential use as preservatives in the food and cosmetic industries (1,2). Essential oils have a complex chemical composition, therefore their antioxidant properties are related to interactions among constituents, which may act synergistically or exhibit antagonistic effects (3).

The antioxidant activity of essential oils is well documented (3,4); however, their uses can be hampered due to the chemical variability related to several factors includ-

ing climatic and agronomic conditions, soil, harvesting time, plant vegetative development and type of isolation (3,5).

Carum carvi L. (Apiaceae) has a long history of use in phytotherapy due to its pharmacological effects (spasmolytic, antifoaming, galactagogue and antimicrobial), but also as spice and flavoring agent in food products (6). The dried fruits contain essential oil (3-7%), with carvone (40-65%) and limonene (30-45%) as main constituents (7).

Continuing our previous researches focused on the influence of agricultural techniques (plant spacing) on the yield and chemical composition of essential oils of several spices (8,9), in this study we aimed to assess the antioxidant activity of essential oil isolated from *Carum carvi* L. cultivated in northeastern Romania.

MATERIAL AND METHODS

Chemicals. All solvents and chemicals were of analytical grade and were purchased from Sigma–Aldrich Chemie (Steinheim, Germany), Merck (Darmstadt, Germany) and Riedel-de Haën (Seelze, Germany).

Plant material. Caraway fruits were collected from biennial plants cultivated in the field of Agricultural Research and Development Center, Secuieni, Neamt county (Romania). A voucher specimen was deposited in the Laboratory of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy *Grigore T. Popa* - Iasi.

Isolation of the essential oil. The essential oil was isolated by hydrodistillation of powdered dried fruits in a Clevenger-type apparatus (3 h) (10), dried over anhydrous sodium sulphate and stored in a sealed glass at -4°C until analysis.

Chemical analysis of the essential oil. Gas chromatography–mass spectrometry (GC–MS) analysis of *C. carvi* essential oil was performed on an Agilent type 7890A gas chromatograph equipped with an Agilent 5975C mass spectrometer and a DB-5MS capillary column (30 m×0.25 mm, 0.25 μm film thickness). The oven temperature was increased with a rate of 10°C/min from 35°C to 280°C (kept isothermally for 7.5 min). The other characteristics of the analysis program were: inlet temperature: 250°C; split ratio: 50:1; carrier gas: helium (flow rate: 1 mL/min); injected volume: 0.2 μL of essential oil. *Gas chromatography (GC) analysis* of *C. carvi* essential oil was carried out using an Agilent 6890 gas chromatograph equipped with a flame ionization detector. The column and GC conditions were the same as the ones described above. *Identification of volatile components.* Individual essential oil components were identified by comparison of their retention indices (RI) relative to (C8–C20) *n*-alkanes with those reported in the literature, and by matching their recorded mass spectra with with those stored in the Wiley 275 mass spectral library from GC-MS database. Quantitative data were obtained from the electronic integration of the FID peak areas.

In vitro antioxidant activity analysis. The antioxidant activity of the essential oil from *C. carvi* fruits was assessed by three methods previously reported (11,12), namely DPPH radical and ABTS radical cation scavenging assays and reducing power test.

In all antioxidant assays butylhydroxyanisole (BHA) was used as positive control. Results were expressed as IC_{50} values (μg/mL), which was calculated through linear interpolation between values above and below 50% activity, except for the

reducing power assay, where IC_{50} value represents the concentration of essential oil/positive control that leads to an absorbance of 0.5. A lower IC_{50} value corresponds to a higher antioxidant activity.

RESULTS AND DISCUSSION

Chemical composition of the essential oil. GC analysis of the essential oil from caraway fruits cultivated in northeastern Romania revealed the presence of twenty compounds, accounting for 98.82% of the total essential oil composition (tab. I).

Carvone (48.53%) was the major compound of caraway fruit essential oil, followed by limonene (44.42%). The chemical class characterization showed that *Carvi aetheroleum* is mainly composed of monoterpene ketones (48.89%), represented by carvone, *cis*-dihydrocarvone and *trans*-dihydrocarvone, and monoterpene hydrocarbons (44.84%) with limonene as main constituent, followed by monoterpene aldehydes (3.09%) and low levels of monoterpene alcohols, oxides and esters, sesquiterpenes and aliphatic compounds (tab. I).

Several factors, including location, genotype, nutrient supply and growing conditions are known to influence carvone and limonene content in caraway fruits (13). Our results are in accordance with those of Laribi *et al.* (14), who reported the predominance of carvone and limonene in essential oils of Tunisian, German and Egyptian caraway ecotypes. Our study revealed that the Romanian caraway essential oil belongs to the carvone chemotype, similar to the caraway essential oils from Tunisia (76.78–80.53% carvone) (15), Serbia (32.3% carvone) (16) and Czech Republic (72.55–81.76%) (17). As carvone is an important flavouring agent in the food industry and has important therapeutic properties (18), Romanian caraway fruits are an important source for the isolation of this monoterpene ketone.

TABLE I

Essential oil composition of caraway fruits from northeastern Romania

RI	Compound	%

In vitro antioxidant activity. Antioxidant activity is very complex, involving a sum of different mechanisms, such as free radical scavenging, prevention of hydrogen abstraction, reducing capacity and binding of transition metal ions (3). Essential oils are complex mixtures of bioactive compounds endowed with multifunctional properties as they have different functional groups and chemical behavior (1). Therefore, the antioxidant activity of *Carvi aetheroleum* was assessed by three different *in vitro* antioxidant assays (DPPH· and $ABTS^{\bullet+}$ scavenging assays and reducing power test) and compared with the activity of a commonly used synthetic antioxidant, BHA (tab. II).

The radical scavenging capacity of the essential oil increased in a concentration-dependent manner (data not shown). Although the DPPH and ABTS methods are based on the same principle, *Carvi aetheroleum* was more potent in reducing the preformed $ABTS^{\bullet+}$ (IC_{50} = 5.34 ± 0.07 µg/mL) than reducing DPPH· to $DPPH_2$ (IC_{50} = 46.51 ± 1.61 µg/mL). In the reducing power assay, caraway essential oil was able to reduce ferric ions (Fe^{3+}) to ferrous ions (Fe^{2+}) in a dose-dependent manner (data not shown) and its IC_{50} value (7.64 ± 0.22 µg/mL) was only 2.2 fold lower than that of the positive control, BHA (3.39 ± 0.07 µg/mL) (tab. II).

However, compared with the standard BHA, in all antioxidant assays caraway essential oil showed significant antioxidant activities (tab. II). A survey of the literature showed that there are several reports on the antioxidant activity of *C. carvi* essential oil (4,19,20), but a direct comparison of our results with those reported in other studies was not possible due to the different experimental protocols and different ways of expressing antioxidant activity.

TABLE II

Antioxidant activities of essential oil of *Carum carvi* fruits cultivated in North-Eastern Romania

Essential oil/positive control	IC_{50} (µg/mL)		
	DPPH· scavenging assay	$ABTS^{\bullet+}$ scavenging assay	Reducing power assay
C. carvi essential oil	46.51 ± 1.61	5.34 ± 0.07	7.64 ± 0.22
BHA	6.09 ± 0.27	1.49 ± 0.00	3.39 ± 0.07

CONCLUSIONS

Our study revealed that the essential oil of *Carum carvi* L. cultivated in northeastern Romania belongs to carvone chemotype. Due to its high antioxidant activity it might be an alternative to conventional preservatives in the food, cosmetic and pharmaceutical industries.

CATECHINS PROFILE, CAFFEINE CONTENT AND ANTIOXIDANT ACTIVITY OF *CAMELLIA SINENSIS* TEAS COMMERCIALIZED IN ROMANIA (Abstract). **Aim**: Catechins profile, caffeine content and antioxidant activity of different green tea and white tea samples commercialized on the Romanian market were investigated. **Material and methods**: Five green tea samples and five white tea samples commonly available on the Romanian market were processed by infusion and the lyophilisates of infusions were analyzed. Total phenolic content was determined using the Folin-Ciocalteu method. Catechins and caffeine profile was analyzed by RP-HPLC-DAD (Agilent Eclipse XDB-C18 column, binary mobile phase (A) 3% acetic acid and (B) methanol). *In vitro* antioxidant activity was assessed by free radical scavenging and ferrous ion chelating assays. **Results and discussions**: Total phenolic content ranged between 44.73±0.63 and 63.57±0.45 GAE% in green tea samples and between 9.69±0.90 and 52.99±0.45 GAE% in white tea samples. RP-HPLC-DAD analysis allowed the identification of epigallocatechin gallate (45.18-118.58 mg/g lyophilisate) and caffeine (47.79-108.07 mg/g lyophilisate) in all tea samples; epicatechin was detected in all samples (5.04-31.04 mg/g lyophilisate) except for two white teas infusions. Green tea samples scavenged DPPH radical and chelated ferrous ion with EC_{50}=9.68±0.02-16.11±0.02 µg/mL and 10.91±0.04-18.65±0.03 µg/mL, respectively. For white teas, EC_{50} values varied between 9.50±0.02-20.95±0.02 µg/mL in DPPH assay and 12.49±0.03-20.32±0.07 µg/mL in ferrous ion chelating assay. **Conclusions**: This study showed a large variability in the content of catechins and caffeine and in the antioxidant capacity of both green and white tea samples. **Keywords**: CATECHINS, CAFFEINE, GREEN TEA, WHITE TEA, ANTIOXIDANT.

Tea is the second most consumed beverage in the world. All types of tea come from the leaves of *Camellia sinensis* (L.) Kuntze (Theaceae), a plant originally native to China, Thailand, Laos and Vietnam (1). Based upon the degree of fermentation, tea can be classified into unfermented tea (white tea and green tea), semi fermented tea (oolong tea) and fully fermented tea (black tea and Pu-erh tea) (2). Tea provides complex chemical substances, like: flavanols (catechins), flavonols and flavones glycosides, proantocyanidols, bisflavanols, theaflavins, thearubigins, theasinensins, caffeine, amino acids and minerals. Catechins are the representative class of compounds from green and white tea, with epigallocatechin-3-O-gallate (EGCG) as the most abundant constituent

(50-80% of the total catechins). Among polyphenols, catechins are primarily responsible for almost all the beneficial effects of tea: antioxidant, chemopreventive, neuroprotective, radioprotective, antimicrobial, anti-aging, hypoglycemiant, and hypolipemiant. Caffeine is the main purine alkaloid of tea with CNS stimulant effects (3).The chemistry and quality of tea are significantly influenced by the environmental conditions of the regions where the plants grow, sampling time, cultivation and processing practices. Therefore, numerous studies have reported a considerable variability among different tea types and brands (2).

The aim of this study was to analyze the catechins profile, caffeine content, and antioxidant activity of different green and white tea samples commercialized on the Romanian market.

MATERIAL AND METHOD

Chemicals

Tris(hydroxymethyl)aminomethane (Tris), hydrochloric acid, and methanol were purchased from Merck (Darmstadt, Germany); Folin-Ciocalteu's phenol reagent, 3-(2-pyridyl)-5,6-diphenyl-1,2,4-triazine-4′,4″-disulfonic acid monosodium salt (ferrozine), and epicatechin (EC) were purchased from Fluka (Steinheim, Germany); iron (II) sulfate heptahydrate, 2,2-diphenyl-1-picrylhydrazyl (DPPH), sodium carbonate, acetic acid, gallic acid, and epigallocatechin gallate (EGCG) were obtained from Sigma-Aldrich (Steinheim, Germany); caffeine was supplied by Carl Roth (Karlsruhe, Germany).

Plant material

Five green tea samples and five white tea samples of different origins (China, India, Vietnam), of different varieties (Bi Luo Chan, Darjeeling, Fanning, Pai Mu Tan), and in different packages were purchased from a local market in Iasi, Romania (tab. I). Voucher samples are deposited in the Department of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy "Grigore T. Popa" – Iaşi, Romania.

	WT3	Unknown	China (packaged in Canada)	Sachet
	WT4	PAI MU TAN	China (packaged in Austria)	Sachet
	WT5	PAI MU TAN	China	Bulk

Bi Luo Chun is one of the most famous ten Chinese teas originated in Dong Ting Mountain (Jiangsu Province). Its specific flavor is determined among other things by various fruit trees (apricot, peach, plum) which are found on tea plantations. After

harvest, the leaves are manually sorted, treated with heat (190-200 °C) for 3-5 min, and then rolled. Darjeeling tea is obtained from plantations located in the region with the same name in West Bengal, India, and it is distinguished by its unique flavor. Plant material consists only of the first two leaves from the top or from the apical buds. The processing of leaves is achieved by exposing them to a hot air flow and subsequent mechanical twisting. In the case of Pai Mu Tan tea ("white peony"), after harvest, tea leaves are sun-dried or dried in closed rooms, without any further technological intervention (4).

Extraction

2 g of tea leaves were placed into boiled water (200 mL) and incubated at 80-90 °C for 3 min. This condition was similar to an actual brewing condition for a cup of tea. After cooling, each sample solution was filtered through Whatman filter papers. Each extract was concentrated under reduced pressure at < 40 °C (Büchi R-210 rotary evaporator, Büchi V-850 vacuum controller, Büchi V-700 vacuum pump, Büchi B-490 heating bath, Büchi, Switzerland) and then freeze-dried (Alpha 1-2 LD Plus freeze-dryer, Christ, Germany).

Total phenolic content

Total phenolic content was estimated using the Folin-Ciocalteu assay. The results were expressed as g gallic acid equivalents (GAE)/100 g extract (5).

RP-HPLC-DAD analysis

Reversed-phase high performance liquid chromatography (RP-HPLC) analysis was conducted on an Agilent 1200 HPLC system (Agilent Technologies, PaloAlto, CA, USA) equipped with a DAD detector. The chromatographic separations were performed on an Agilent Eclipse XDB C-18 (150 mm x 4.6 mm, i.d. 5 µm) column, with column temperature set at 20 °C. The binary mobile phase consisted of (A) 3% acetic acid and (B) methanol; the flow rate was 1 mL/min; the detection wavelength was set at 280 nm. The gradient elution profile started with 0% B; then B was gradually increased to 5% at 10 min, to 10% at 35 min, to 50% at 45 min, maintained at 50% at 50 min, and decreased back to 0% at 55 min [6]. Catechins and caffeine were identified by comparing their UV spectra and retention times with those of commercial standards. EGCG, EC and caffeine were quantified on the basis of their calibration curves (0.125-1 mg/mL), and the results were expressed as mg compound/g lyophilisate. The calibration curves were: for EGCG: A=1227.3c-69.206, R^2=0.9997; for EC: A=504.72 c+19.928, R^2=0.9998; for caffeine: A=1790.4c+9.114, R^2=1.

DPPH radical scavenging assay

DPPH (1,1-diphenyl-2-picrylhydrazyl) radical scavenging assay was performed according to Malterud et al (7, 8, 9). Epicatechin was used as positive control. The radical-scavenging activity (%) was calculated as follows: %=[(absorbance of DPPH solution - absorbance of DPPH solution with sample after 5 min)/absorbance of the DPPH solution]×100.

Ferrous ion chelating ability assay

This assay was done according to Dinis et al (10). Epicatechin was the positive control. The percent inhibition of Fe^{2+}-ferrozine complex formation was calculated according to the following equation: % inhibition=[(absorbance of control - absorbance of sample)/absorbance of control]×100.

Statistical analysis

All experiments were conducted in triplicate. The results were expressed as mean

± standard deviation (SD). The EC_{50} values were calculated by linear interpolation between values above and below 50% activity.

RESULTS AND DISCUSSION

Phenolic content and profile

The total phenolic content ranged between 44.73±0.63 and 63.57±0.45 g GAE% in green tea samples and between 9.69±0.90 and 52.99±0.45 g GAE% in white tea samples, respectively (fig. 1). Green tea samples contained higher amounts of polyphenols compared to white tea samples. RP-HPLC-DAD analysis revealed the presence of EGCG in all infusions; EC was detected in all samples except for two white tea samples (WT1 and WT5) (fig. 2). Also, caffeine was identified in all tea samples. EGCG was the major catechin in tea samples; it has been found in concentrations between 49.85 and 118.58 mg/g lyophilisate in green teas. In white tea samples, EGCG concentrations were lower (45.18-85.01 mg/g lyophilisate), and four samples had a concentration of less than 65 mg EGCG/g lyophilisate (fig. 3). Although green tea contained higher amounts of EGCG, the variability of its content was much higher than in white tea samples. This may be due to the fact that commercial samples of green tea were more heterogeneous (Darjeeling, Fanning, Bi Luo Chun) while white tea samples were predominantly Pai Mu Tan. Compared to EGCG, the EC content values were much lower (5.04-31.04 mg/g lyophilisate) (fig. 4); GT4 green tea sample contained the highest concentration of EC. The content of EC can vary up to 6 times between the two types of tea.

Except WT2 sample that contained 27.79 mg EC/g lyophilisate, all other white tea samples showed lower concentrations of EC (5.04-8.76 mg/g lyophilisate) compared to green teas; therefore, white tea was characterized by a more pronounced heterogeneity. Regarding caffeine content, all samples of green tea had at most 65.19 mg/g lyophilisate (GT3); in white tea, the amounts of caffeine were found to be higher (67.44-108.07 mg/g lyophilisate) (fig. 5).

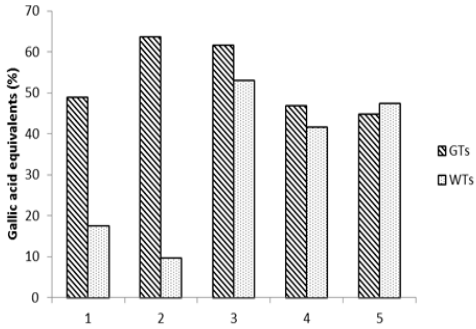

Fig. 1. Total phenolic content of tea samples

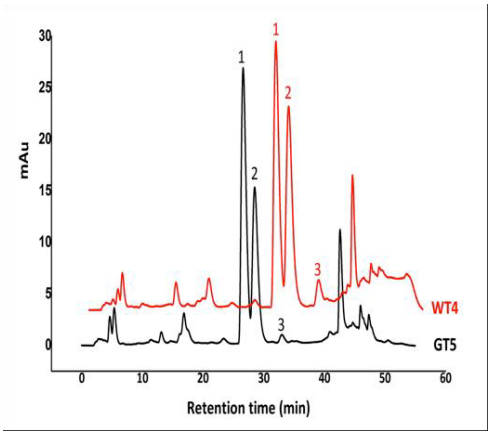

Fig. 2. RP-HPLC-DAD of tea samples (1-caffeine, R_t=29.49 min; 2-EGCG, R_t=32.69 min; 3-EC, R_t=37.36 min; GT-green tea, WT-white tea)

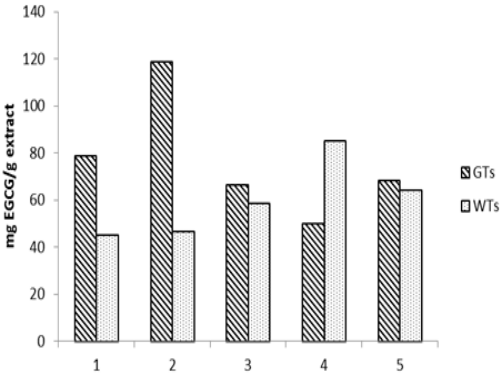

Fig. 3. EGCG concentration of tea samples

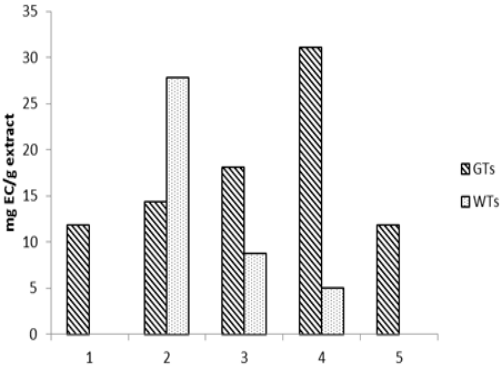

Fig. 4. EC concentration of tea samples

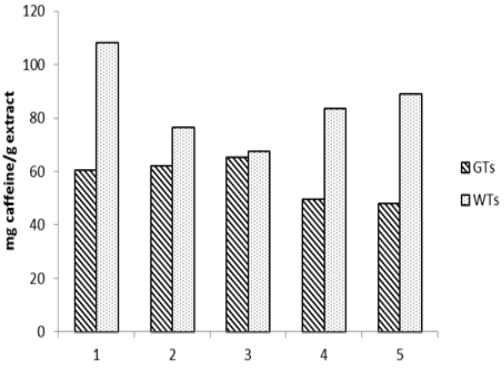

Fig. 5. Caffeine concentration of tea samples

DPPH radical scavenging assay

Both types of tea scavenged DPPH radical in a concentration dependent manner; at the concentration of 41.66 μg/mL, all samples with the exception of WT2 showed a DPPH radical scavenging activity higher than 90% which was similar to that of the positive control (EC) (tab. II).

At the concentration of 10.41 μg/mL, DPPH radical scavenging activity of samples decreased reaching values lower than 50%. Therefore, at low concentrations we noticed a greater heterogeneity of DPPH radical inhibitory activity: between 30.26% and 64.15% for green tea samples, and between 23.28% and 53.55% for white tea samples, respectively. DPPH scavenging activity of white tea samples was lower than that of green teas. The samples of white tea showed a greater variability of free radical scavenging activity (EC_{50}=9.50±0.02-20.95±0.02 μg/mL) than that of green tea (EC_{50}=9.68±0.02-16.11±0.02 μg/mL) (tab. II).

Ferrous ion chelating ability assay

Ferrous ion chelating abilities of both types of tea samples increased with concentration. At the concentration of 41.66 μg/mL, all tea samples showed the highest values of ferrous ion chelating activity (77.79±0.20%-92.26±0.19% for white teas and 88.35±0.21-99.31±0.16% for green teas, respectively) (tab. III). Overall, green tea samples were more active as ferrous ion chelating agents (EC_{50}=10.91±0.04-18.65±0.03 μg/mL) than white teas (EC_{50}=12.49±0.03-20.32±0.07 μg/mL). Also, some of the samples, either green tea or white tea, were even more potent than the positive control, EC (EC_{50}=15.44±0.01 μg/mL) (tab. III).

TABLE II

CONCLUSIONS

In our study, samples of green tea were characterized by a richer content in total polyphenols (that can be almost 5 times higher) compared to white teas. EGCG and EC were found in higher concentrations in green teas. EGCG content showed a higher degree of variability in green tea samples

while EC content exhibited a great heterogeneity in white teas. The highest concentrations of caffeine, exceeding 65 mg/g lyophilisate, were identified in white teas samples. Overall, green tea samples were more active as free radical scavengers and ferrous ion chelating agents than white tea samples.

PATIENTS' PERCEPTION TOWARDS INFECTION TRANSMISSION IN DENTAL PRACTICES IN IASI, ROMANIA (Abstract): **Aim**: To assess patients' perception and attitudes concerning the risk of infection transmission in dental practices in Iasi, Romania. **Material and methods:** A questionnaire-based study was conducted amongst 280 patients aged between 21 and 62 in 32 private dental offices in Iasi, Romania. The 16 questions were related to patients' attitude towards the risk of infection and their involvement in assessing the safety protocols. The data were analyzed by gender, age and education level using the *SPSS 15.0* statistical package ($p<0.05$) and Chi square test. **Results:** Most patients (82.6%) manifest their trust in the medical staff to protect them against the spread of infection. 10,9% of the subjects avoid dental care as a result of the risk of getting infected. 46,5% of the patients are concerned about the safety measures used during their dental treatment. Women desire to involve themselves in assessing the implementation of infection control measures more than men (63.6%, 50.0%, respectively). HIV infection, viral hepatitis B and C and influenza are considered by the patients to be the most frequently transmitted during dental treatment. Older subjects (81.4%) and those with secondary educational level (67.3%) do not consider that their implication in infection control is necessary. The dental assistant is associated with infection transmission by 62.7% of patients. **Conclusions**: The assessment of patients' specific requirements and needs is essential in order to increase the medical team knowledge and awareness regarding the level of patient safety. **Keywords:** PATIENT PERCEPTION, DENTAL PRACTICE, INFECTION PREVENTION.

The high quality standards of modern dentistry imply major demands regarding patient safety and infection risk management. The patient safety is a complex concept involving social, economical, financial, cultural, and management issues with major benefits regarding the quality of the dental treatment (1). In the dental office the germs can be transmitted by direct contact with blood and contaminated saliva, indirectly through contaminated objects (surfaces, instruments or equipments) but also from one patient to another by medical personnel (cross-infection) (2).

The advanced specific dental procedures, the unique relationship between the patient and the dentist, as the medical technological progress require not only a continuous adaptation of infection control protocols but also an increased concern of the medical staff and public in this domain (3).

The actual public high level of health

education influences the patient requirements regarding the protection from infectious diseases like HIV infection, viral hepatitis B and C, tuberculosis and respiratory infections. The educated patient's participation in his own treatment must increase the responsibility of the dentist and his team for the safety of the dental procedures (4).

MATERIAL AND METHODS

The study based on an anonymous questionnaire included 280 patients in 32 private dental practices in Iasi, Romania.

The self-administrated questionnaire comprised 16 questions regarding the patient's trust in the medical team, the desire to assess medical procedures safety, dentist's protective equipment, attitudes towards infection control, knowledge concerning diseases which can be transmitted during dental treatments and procedures with high risk of infection (tab. I). Patients were asked to answer the survey questions in the waiting room of the dental offices and their participation was voluntary.

TABLE I.

Questionnaire for patients' opinion assessment

No.	*Question*
1.	Do you trust the medical staff to protect you against the transmission of infectious diseases during the dental treatment?
2.	Do you think you could get sick during dental treatment?
3.	Do you avoid the dental treatment because of the fear of getting infected?
4.	Do you consider you have to get involved in checking the measures to prevent infection transmission in the dental office?
5.	Did you discuss with your dentist about the risk of contracting infectious diseases throughout the dental treatment?
6.	Did you watch the application of the protocols for preventing the transmission of infectious diseases during dental treatments?
7.	Which are the diseases that pose a threat during dental treatment : hepatitis A, hepatitis B, hepatitis C, HIV infection, tuberculosis, influenza?
8.	Do you accept to be treated in the same dental office where an HIV infected patient was treated?
9.	Do you consider that the dentist appearance increases the confidence in the safety of the dental treatments?
10.	Do you want the dentist to wear protective equipment (gown, mask, gloves)?
11.	Do you consider that these equipments protect you against the infection transmission?
12.	Which are the dental instruments associated with a high risk of disease transmission during dental treatment: dental drills, endodontic needles, scaling instruments, dental extraction instruments, scalpels?
13.	Which are the factors incriminated in infection transmission (instrument sterilization failure, surfaces and equipments disinfection deficiencies, poor compliance of dental personnel to protective equipment)
14.	Which of the following maneuvers are important in preventing infection transmission during dental treatment: medical staff hand washing, use of an individual kit of instruments for each patient, dental unit disinfection, changing the glass for mouth rinses for each patient, changing the mask and gloves after each patient?
15	Do you think dental assistant may be involved in the transmission of the infectious diseases during dental treatment?
16.	Do you consider the dental assistant should wear protective equipment (gown, mask, gloves)?

A cross-sectional epidemiological study was initiated, the data being analyzed by age, gender and educational level. The data was processed using the *SPSS 15.0* statistical package (statistical significance $p<0.05$) and *Chi square test.*

RESULTS

The survey included 37% men and 63% women aged between 21 and 62. Depending on age, the structure of the study group was as follows: 41, 7% in the 20-30 years old group; 28.4%, 31-40; 20.7%, 41-50 and 9.2% in the over 51 years old group (tab. II).

TABLE II

Structure of the patients study group by age

No	*Age group (years)*	*Percentage of patients (%)*
1.	20-30	41.7
2.	31-40	28.4
3.	41-50	20.7
4.	over 51	09.2
	TOTAL	100.0

Regarding the educational level, 26.5% of the subjects were highly educated, 45.2% had a secondary level education and 28.3% a primary level of education.

The data from the questionnaires revealed that most of the subjects (87.3%) trust the dental medical professionals to protect them against infectious diseases transmission. 10.9% of the respondents avoid dental treatment because they feel exposed to infections. 1.8% of the patients had no opinion on this matter.

Men showed a higher level of confidence in the medical staff than women (94.5%, 75.8% respectively) (fig.1).

About half of subjects (46.5%) expressed their interest in infection control protocols applied after each patient (environmental surface disinfection, changing the protective equipment, hands hygiene). Among those, the majority are young active people included in the groups of 20-30 years of age (44.8%) and 31-40 years of age (37.3%). Regarding the gender, women desire to involve themselves in assessing the implementation of infection control measures more than men (63.6%, 50.0%, respectively). A significant proportion of older subjects (81,4%) and of those with secondary educational level (67.3%) do not consider that their implication in infection control is necessary. 1.9% of the subjects are not interested in those aspects and 12.7% admit that they do not have the necessary knowledge in this domain (fig. 2).

In terms of patient–doctor communication, 27.5% of the patients have discussed with their dentist about the risk of contracting infectious diseases throughout the dental treatment, women being more interested in this topic than men (43.4% and 28.3%, respectively). Patients in the 31-40 age groups are the most interested to receive information about the risk of diseases transmission and the methods to decrease this risk (58.5%).

The severe diseases as HIV infection, viral hepatitis B and C, but also influenza and tuberculosis are considered by the patients to be frequently transmitted during dental treatment (100%, 76.3%, 82.5%, 96.5% and 23.7%, respectively) (fig.3). The HIV infection is a major concern for subjects with a secondary level of education (82.7%) while the highly educated patients give a greater importance to the risk to get infected with hepatitis B and C viruses (75.4%).

Regarding the attitude towards HIV infection, 86.5% of patients do not accept to get theirs treatment in a dental office in which an infected patient was previously attended to.

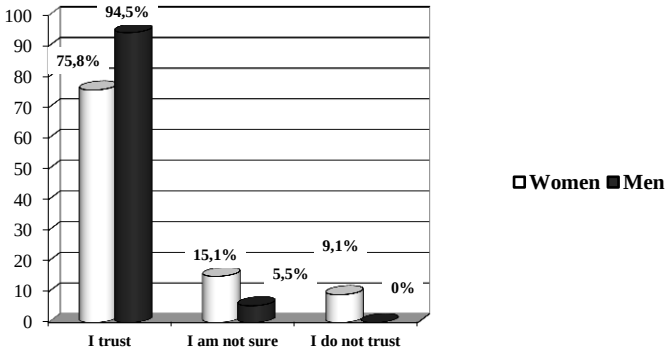

Fig.1. Dental patients' confidence in dentist by gender

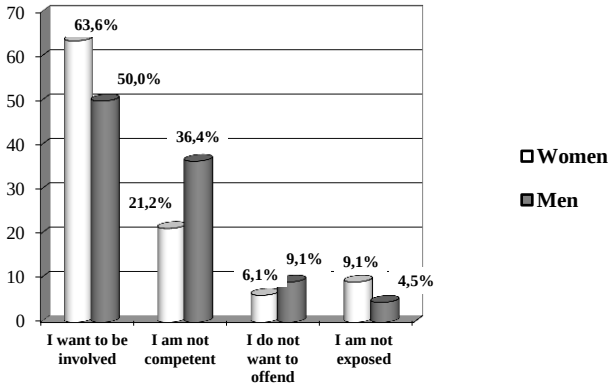

Fig.2. Patients' involvement desire in infection control by gender

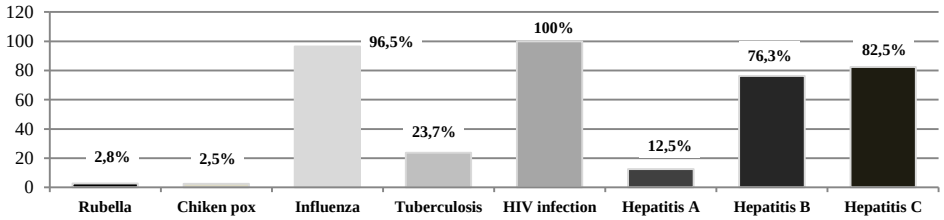

Fig. 3. Infectious diseases considered as having a high risk of transmission

The subjects' answers demonstrate that most of them desire the medical team to always use the protective equipment: rubber gloves (88.0%), face mask (63.6%) and protective glasses (47.2%); doctor's hair protection is a concern for only 27.7% of the patients. 97.3% of the patients feel protected from infectious diseases by the use of those barriers, with no significant differences by gender, age or education level.

Most of patients (67.8% women and 76.8% men) believe that dental assistant is involved in the transmission of infection and should use the same equipment as the dentist.

A significantly high percentage (65.5%),

especially highly educated individuals and women, appreciate that the patient's satisfaction over the medical care quality and safety is increased by the dentist's professional attire. 23.6% would like the traditional white gown and over half of the patients would like the doctor to wear an ID badge.

The failure of instruments' sterilization as well as the deficiencies in surfaces and equipments disinfection in the dental practice are regarded by most patients as the main cause of infection transmission (80.0% and 54.5%, respectively).

The most efficient infection control methods considered to ensure the safety in the dental practice are: dental personnel hands washing (78.2%), environmental surfaces disinfection (56.4%) and the safe manipulation of the instruments between patients (45.5%).

DISCUSSION

Given the complexity of clinical procedures in the dental office, the patient safety and protection represent an important challenge during oral health care. The dental medical personnel must take the proper measures in order to avoid the risk of infection transmission by applying the needed methods and protocols in the spirit of the Standard Precautions concept. In this context the patient must be considered as a partner in his own oral health care whose needs and opinions should be respected. The results of our study highlight that majority of patients trust the medical staff to protect them by applying the needed infection control procedures. However, a high percentage of the patients, especially men, expressed their concern about catching an infection during dental treatment. Our results are similar to those reported by Smith et al. regarding the patients' perceptions of risk, the major concerns of patients revolving around hand hygiene practices rather than risks from bloodborne viruses and Creutzfeldt-Jacob Disease (5).

The young subjects and women mainly expressed their concerns regarding the taken measures to reduce the risk of infection transmission, whereas the older patients claim their lack of knowledge in this domain or the desire to avoid offending the medical staff.

The dentist's protective equipment is perceived to have major benefits in patient's safety by acting as a barrier against contaminated fluids, especially blood and saliva. Rubber gloves are considered the most efficient barrier but the facial mask and the protective glasses are also required, the results of our study being similar to those reported in the literature. In his study Barghout reported that 83.5% of the respondents are of the opinion that the dentist must wear gloves and 74.8% want him to wear facial masks (6). These results demonstrate a positive, encouraging evolution of the public knowledge regarding the safety of the dental treatment compared, for example, with the data obtained by Samaranayake who reported in 1990 for the Glasgow region that the majority of the patients were not interested at all in the protective equipment (gloves or masks) and one third of them lacked knowledge about dental instruments sterilization methods (7).

The patients expressed their desire to get involved in the dental care in a low percentage as a consequence of their lack of knowledge in the domain of infection transmission risk, but also due to the confidence in the professionalism and responsibility of the medical team. The highly educated patients wish to be informed and to have the opportunity to evaluate the infection control protocols used in the dental office.

Regarding the dentist's professional at-

tire our findings confirm the results of other investigations revealing the patients' preferences for traditional medical appearance (8,9). Highly educated subjects consider that the doctor's appearance reflects the level of his professional training and is related to treatment quality and safety. The majority of patients want the medical team to wear an ID badge which is seen as a sign of assuming the medical procedure responsibility, a proportion similar to that reported by Shulman in his survey involving 1500 subjects (10). An effective communication with the dentist and a patient-dentist relationship based on trust and respect is considered, especially by the patients with a high level of education, to ensure the increased quality level of the dental treatment (11,12).

CONCLUSIONS

The results of our study demonstrate that majority of patients trust the dentist to use the proper safety measures and this fact should motivate the medical team in complying with the safety standards. The beneficiaries of oral health care have a realistic perception regarding the importance of the protective equipment and should be encouraged to request, accept and supervise the safety procedures in the dental practice.

FIXED DOSE COMBINATIONS WITH SELECTIVE BETA-BLOCKERS: QUANTITATIVE DETERMINATION IN BIOLOGICAL FLUIDS (Abstract): Hypertension is one of the most common causes of death, a complex and incompletely controlled disease for millions of patients. Metoprolol, bisoprolol, nebivolol and atenolol are selective beta-blockers frequently used in the management of arterial hypertension, alone or in fixed combination with other substances**.** This study presents the most used analytical methods for simultaneous determination in biological fluids of fixed combinations containing selective beta-blockers. Articles in PubMed, Science Direct and Wiley Journals databases published between years 2004-2014 were reviewed. Methods such as liquid chromatography–mass spectrometry–mass spectrometry (LC-MS/MS), high performance liquid chromatography (HPLC) or high performance liquid chromatography–mass spectrometry (HPLC-MS) were used for determination of fixed combination with beta-blockers in human plasma, rat plasma and human breast milk. LC-MS/MS method was used for simultaneous determination of fixed combinations of metoprolol with simvastatin, hydrochlorothiazide or ramipril, combinations of nebivolol and valsartan, or atenolol and amlodipine. Biological samples were processed by protein precipitation techniques or by liquid-liquid extraction. For the determination of fixed dose combinations of felodipine and metoprolol in rat plasma liquid chromatography–electrospray ionization–mass spectrometry (LC-ESI-MS/MS) was applied, using phenacetin as internal standard. HPLC-MS method was applied for the determination of bisoprolol and hydrochlorothiazide in human plasma. For the determination of atenolol and chlorthalidone from human breast milk and human plasma the HPLC method was used. The analytical methods were validated according to the specialized guidelines, and were applied to biological samples, thing that confirms the permanent concern of researchers in this field. **Keywords:** HYPERTENSION, SELECTIVE BETA-BLOCKERS, FIXED DOSE COMBINATION, HPLC, LC-MS/MS.

Arterial hypertension is one of the most common cardiovascular diseases with serious chronic complications such as heart failure, hypertensive cardiopathy, severe renal failure, hypertensive encephalopathy or lower limb peripheral arterial disease (1). According to statistics from the World Health Organization (WHO) in 2012 approximately 33.3% of the population had cardiac problems, data obtained from 194

countries (2). The prevalence of this disease in Romania is between 40% and 44.92%. A retrospective study including 1064 patients, conducted between January 2011 and December 2012 in Iasi, showed a prevalence of hypertension of 38.72% men and 61.28% women with ages between 40-80 years (3). The occurrence of hypertension is favored by behavioral type (41.2%), high fat diet (38.2%), sedentary life (25.8%), excess salt (9.0%), and also passive smoking (4.7%) (4).

Beta-blockers have been described for the first time in 1964, being initially administered for angina and arrhythmias. Subsequently, their spectrum of indications was extended and was approved by the Food and Drug Administration (USFDA) as antihypertensive agents in 1967. They are classified according to their selectivity for ß1 or ß2 receptors in non-selective and ß1 selective beta-blockers. Distribution of beta-adrenergic receptors varies depending on the species and organ system. ß1-adrenergic receptors are mainly present in cardiac and adipose tissues, and ß2 receptors in vascular tissue.

The action mechanism of selective beta-blockers is multifactorial supposing decreased cardiac output, central nervous system effects, resetting of baroreceptor levels, and reduction in vasomotor tone and plasma volume. Competitive ß-adrenergic receptor antagonism is responsible for blood pressure lowering.

Selective beta-blockers such as metoprolol, bisoprolol, nebivolol and atenolol are recommended for hypertension control alone or as fixed combinations with substances from other drug classes such us diuretics, lipid-lowering agents, calcium channel blockers and angiotensin-converting enzyme inhibitors (5).

Both the Brithish Hypertension Society guidelines and the Sixth Report of the Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure recommend fixed combinations containing selective beta-blockers and thiazide diuretics as first choise medication. Thiazide diuretics are designed to minimize sodium retention and increase antihypertensive efficacy when fixed dose combinationsare used.

Non-dihydropyridine calcium channel blockers, such as verapamil and diltiazem should be avoided in fixed combination with selective beta-blockers because of the risk of symptomatic bradycardia and atrioventricular block. Instead, a proven efficacy have shown the combinations with selective beta-blockers and dihydropyridine calcium channel blockers, such as nifedipine, amlodipine, felodipine. Following the administration of metoprolol and felodipine it has been noticed that selective beta-blockers suppress renin secretion which potentiates the vasodilatory properties of calcium channel blockers. In the case of fixed combination with atenolol, a selective long-acting beta-blocker, and nifedipine, with short duration of action, the effect is not so obvious, but it is a combination fairly used to treat hypertension.

Studies have shown that the blood pressure lowering effect after the administration of a selective beta-blocker with an angiotensin-converting enzyme inhibitor is less obvious than after the administration of a fixed combination with a beta-blocker and a thiazide diuretic (6).

The potential disadvantages of fixed combinations with selective beta-blockers include the increased risk of adverse effects and drug interactions. The initial doses are lower than those administrated alone, so it

is harder to achieve the desired plasma concentration, fact that increases the risk of orthostatic hypotension in elderly patients and in those with diabetic autonomic neuropathy (7).

Due to the complex composition of biological fluids, before applying quantitative analysis method a pre-treatment of the biological samples required in order to remove proteins and potential interferences. Currently known and widely used techniques for the preparation of the biological samples are protein precipitation, liquid-liquid extraction and solid phase extraction. Protein precipitation technique has the advantage of simplicity and universality for drug molecules in plasma, but the interferences are high and the amount of substance recovered is reduced. Instead, the liquid-liquid extraction not only purifies, but also concentrates the sample, and is a commonly used technique (8).

The most used analytical methods for quantitative determination in biological fluids of the fixed dose combinations which contain selective beta-blockers were identified by consulting the publications in PubMed, ScienceDirect, and Willey Journals databases, from years 2004-2014. Were used methods such as: liquid chromatography–mass spectrometry–mass spectrometry (LC-MS/MS), liquid chromatography–atmospheric pressure ionization–mass spectrometry (LC-API-MS/MS), liquid chromatography–electrospray ionization–mass spectrometry (LC-ESI-MS/MS), high performance liquid chromatography (HPLC) or high performance liquid chromatography–mass spectrometry (HPLC-MS) (tab. I).

* Not specified

In this study are presented the techniques for processing biological samples, methods for extracting drug substances from biological fluids, respectively the solvents used for extraction (tab. II). It is noticed that the most widely used sample preparation technique is liquid-liquid extraction.

The most prescribed combinations in the treatment of hypertension are those that contain selective beta-blockers and thiazide diuretics. As methods for quantitative determination were described LC-MS/MS for analysis of fixed combination with metoprolol and hydrochlorothiazide in human plasma (11), HPLC-MS for bisoprolol and hydrochlorothiazide (14), also HPLC for atenolol and chlorthalidone in human plasma and human milk breast (16, 19). For fixed combinations with selective beta-blockers and calcium channel blockers, LC-ESI-MS/MS is the method used to determine a combination of metoprolol and felodipine in rat plasma (13), and also of atenolol and nifedipine in human plasma. For the analysis of the combination containing a selective beta-blocker and amlodipine in human plasma LC-MS/MS was used (12, 18). LC-MS/MS has been applied also for the simultaneous determination in human plasma of metoprolol and ramipril, using atenolol as internal standard (12). Various separation columns, mobile phases and internal standards are used in each case (tab. III).

TABLE III

Particularities of analytical methods used for simultaneous determination of fixed combinations with selective beta-blockers

Method of analysis	Separation column	Mobile phase	Flow rate	Internal standard	Lower limit of quantification	References
LC-MS/MS	Gemini-C18 (50 mm x 2.0mm i.d., 3µm, Phenomenex, Torrance, USA)	Acetonitrile –formic acid 0,5% (90:10, v/v, pH 3.5)	0.2 mL/ min	Propranolol hydrochloride	1.0 ng/mL for metoprolol and 0.1 ng/mL for simvas-tatin	Selvan, 2009 (9)
LC-MS/MS	Peerless basic C18 column (33mm x 4.6mm, 5µm, Chro-matopak, India)	Methanol –water containing 0.5% formic acid (8:2, v/v)	1 mL/ min	Hydrochloro thiazide	1.5 ng/mL for metoprolol and 1.25 ng/mLfor amlodipine	Sarkar, 2008 (10)
LC-MS/MS	Venusil MP - C18 column (100 mm x 4.6mm, 5µm)	Methanol – ammonium acetate – formic acid (50:50:0.05 v/v/v, pH 3.4)	0.8 mL/ min	Tramadol for metoprolol, 5-bromouracil for hydrochloro thiazide	3 ng/mL for both analytes	Gao, 2010 (11)
LC-MS/MS	C8 column (50mm x 3mm i.d., 3µm, Phenomenex, USA)	Methanol – 10mM ammonium formate (97:3, v/v)	1 mL/ min	Atenolol	5 ng/mL for both analytes	Gowda, 2007 (12)
LC-ESI-MS/MS	Atlantis C18 column (50 mm x 4.6mm, 3µm, Waters, USA)	0.2% formic acid in water – acetonitrile (25:75, v/v)	0.4-0.7 mL/ min	Phenacetin	0.53 ng/mL for metoprolol and 0.59 ng/mL for felodipine	Kallem, 2012 (13)
LC-MS/MS	Diamonsil C18 column (50 mm x 4.6mm, 5µm)	Methanol – water – formic acid (75:25:0.01, v/v/v)	0.3 mL/ min	Clenbuterol	0.2 ng/mL for both analytes	Chang, 2012 (8)
HPLC-MS	Purosphere STAR C8 column (125mm x 4mm, 5µm, Merck, Germany)	Ammonium acetate (1mM) with formic acid (0.2%) – methanol – acetonitrile (65:17.5:17:5, v/v/v)	0.65 mL/ min	Moxifloxacin	0.1 ng/mL for bisoprolol and 1.00 ng/mL for hydrochlo-ro thiazide	Tutunji, 2009 (14)
LC-MS/MS	Gemini C18 column (50 mm x 2mm i.d., 3µm) with a Security Guard C18 column (4 mm x 3mm i.d., Phenome-nex, Torrance, USA)	Acetonitrile – 0.05mM formic acid (50:50, v/v, pH 3.5)	0.25 mL/ min	Tamsulosin	0.01 ng/mL for nebivolol and 1.0 ng/mL for valsartan	Selvan, 2007 (15)
HPLC	Shim-pack cyanopropyl column (250 x 4.6mm i.d., 5µm, Shimadzu, Japan)	10mM KH_2PO_4 (pH 6) –methanol (70:30, v/v)	1mL/m in	Hydrochloro thiazide	0.2 ng/mL for atenolol and 0.129 ng/mL for chlorthali-done	Elgawish, 2011 (16)

CONCLUSIONS

The results of recent developments in the use of fixed dose combinations with selective beta-blockers and simultaneous determination of the components of these combinations in biological fluids facilitates the evaluation of pharmacokinetic parameters, respectively the evaluation of bioa-

vailability.

In the field of cardiovascular diseases, the methods used for simultaneous determination of selective beta-blockers from combinations with other substances are essential because of the continued need for therapeutic monitoring of plasma drug levels. The analysis methods were validated according to USFDA 2001 international guideline for validation of bioanalytical methods, by determining the following parameters: specificity, linearity, selectivity, accuracy, precision, robustness, stability, and limit of quantification. The described methods have proven high precision and accuracy in the quantitative determination of fixed combination with selective beta-blockers in human plasma, rat plasma and human milk breast. This facilitates application of the analysis methods in studies of bioavailability, bioequivalence, toxicological and clinical studies, and also for monitoring drug-drug interactions in human subjects.

NEWS

MYOFIBROBLASTS IN HEALTH AND DISEASE

Myofibroblasts are present in organs with a high remodelling capacity such as kidneys, lungs and the periodontal ligament or during increased remodelling, such as in growth, development, inflammatory responses and the contraction of healing wounds. Myofibroblasts, as first described in 1971 cause the extracellular matrix to contract and are occupied in the regulation of proliferation and differentiation of neurogenic, vascular and epithelial cells. Myofibroblasts play a significant role in oncogenesis, inflammation, repair, organogenesis and fibrosis in various organs and tissues by the secretion of inflammatory and anti-inflammatory cytokines, both lipid and gaseous inflammatory mediators, chemokines, growth factors as well as extracellular matrix proteins and proteases. This smooth muscle like cells or myofibroblasts take part in development, growth and repair of normal and disease affected tissues and organs. Because of their presence everywhere in all tissues, myofibroblasts play significant roles in numerous diseases of the organs and probably in multisystem diseases also. Understanding the role of the stromal cells and extracellular matrix will allow us to identify more precise prognostic markers and potentially new therapeutic options and prevent various diseases caused by these miraculous multipotential cells. New studies can help us to use only beneficial effects of myofibroblasts and control their activation wherever they act hyperactive (Pallavi D. Shirol, Dayanand D. Shirol. Myofibroblasts in Health and Disease. International Journal of Oral & Maxillofacial Pathology. 2012; 3 (1): 23-27).

ARMILLARIA MELLEA: PHENOLIC CONTENT, *IN VITRO* ANTIOXIDANT AND ANTIHYPERGLYCEMIC EFFECTS (Abstract): *Armillaria mellea*, known as honey mushroom, has been used both as food and medicine. **Aim**: In this work, the ethanolic and hydromethanolic extracts from *Armillaria mellea* fruiting bodies were investigated for their phenolic content, antioxidant and antihyperglycemic effects (*in vitro* studies). **Material and methods**: The total phenolics were quantified using Folin-Ciocalteu assay. The antioxidant activity was evaluated by testing the free radical scavenging capacity, reducing power and ferrous ion chelating ability; in addition, the capacity to inhibit 15-lipoxygenase was also assessed. The antihyperglycemic activity was investigated by α-glucosidase assay. **Results**: Total phenolic contents of 21.68 ± 0.06 and 5.70 ± 0.28 mg/g were determined in the hydromethanolic and ethanolic extracts, respectively. The hydromethanolic extract showed higher free radical scavenging and reducing abilities (EC_{50} = 452.6 ± 2.7, 140.57 ± 1.45 and 129.45 ± 0.98 μg/mL in DPPH, ABTS and reducing power assays, respectively). The ethanolic extract proved to be more efficient in the ferrous ion chelation, 15-lipoxygenase and α-glucosidase inhibition assays (EC_{50} = 67.93 ± 0.35, 290.93 ± 2.05 and 8.54 ± 0.06 μg/mL, respectively). **Conclusions**: *Armillaria mellea* extracts showed antioxidant and antihyperglycemic potential in *in vitro* models and therefore they are promising candidates for the development of dietary supplements and pharmaceutical products. **Keywords**: *ARMILLARIA MELLEA*, FREE RADICALS, 15-LIPOXYGENASE, α-GLUCOSIDASE.

Since centuries wild edible mushrooms have been used both as food and medicine. Wild edible mushrooms are an important source of nutrients (proteins, essential aminoacids, fatty acids, carbohydrates, vitamins, mineral elements). In addition, they contain non-nutrient compounds such as phenolics, terpenes, steroids, polysaccharides. For many of these non-nutrients there have been reported different biological effects (antioxidant, antitumor, anti-inflammatory, antimicrobial, antidiabetic, hypocholesterolemic, anti-atherosclerotique, hypotensive effects) (1, 2).

Armillaria mellea (Vahl) P. Kumm. (Basidiomycota, honey mushroom) is a wild edible mushroom which grows on the stumps and roots of a wide variety of

woody and herbaceous plants. It has been traditionally used in the treatment of headache, neurasthenia, insomnia, infectious diseases and cancers (3-5). Different phytochemicals have been isolated/identified in the fruiting bodies of *A. mellea* from different geographic regions: carbohydrates (glucose, xylose, trehalose, D-mannitol, D-erythritol, glucans), peptides (prosomatostatin), sphingolipids (armillar-amide), sterols (ergosterol, ergosterol peroxide), fatty acids (oleic, linoleic, palmitic and stearic acids), sesquiterpenoids (protoilludan derivatives such as armillarin, melleolid, melledonal A, B and C), phenolics (*p*-hydroxybenzoic and cinnamic acids) and indole compounds (serotonin, tryptamine, tryptophan). Some of these phytochemicals (β-glucan with a peptide component, prosomatostatin, ergosterol peroxide) have been reported to possess anticancer properties (4, 5). Besides, extracts from the fruiting bodies of *A. mellea* showed anti-inflammatory (inhibition of the expression of inducible NO synthase, cyclooxygenase-2, prostaglandin E2, tumor necrosis factor-α, interleukin-4, -8) and immunomodulating effects [modulation of the expression of cluster of differentiation (CD) molecules, namely an increase in the expression of CD80, CD83, CD86, CD205 and a decrease in the expression of CD206, a decrease in the endocytic capacity of human dendritic cells] (*in vitro* studies) (3, 6).

A literature survey revealed antioxidant studies on extracts from Chinese and Portuguese samples of *A. mellea* (5). To the best of our knowledge, possible biological effects of Romanian samples of *A. mellea* have not been investigated yet. Besides, there are no literature reports on *A. mellea* capacity to scavenge ABTS radical cation and to inhibit 15-lipoxygenase and α-glucosidase. In this respect, the present study reports on the *in vitro* antioxidant and antihyperglycemic potential of *A. mellea* collected from Iasi region in relation to its phenolic content.

MATERIAL AND METHODS

Chemicals and reagents. All chemicals and reagents were of analytical grade.

Mushroom material. Samples of *A. mellea* were collected in Dobrovat forest (Iasi County) in October 2012. The identity of the mushroom material was confirmed by Prof. Catalin Tanase, PhD, (*Alexandru Ioan Cuza* University of Iasi). The mushroom material was cleaned without washing and air dried in shade. A voucher specimen is deposited in the Laboratory of Pharmacognosy, Faculty of Pharmacy, "*Grigore T. Popa"* University of Medicine and Pharmacy – Iasi.

Extraction. Dried and powdered mushroom material (50 g) was extracted with 500 mL of 96% ethanol at room temperature for 3 h; the extraction was repeated once. The combined ethanolic extracts were evaporated at 40°C under reduced pressure giving the ethanolic extract. The residue was extracted with methanol:water mixture (1:1, v:v) using the same procedure; the combined extracts were evaporated at 40 °C under reduced pressure giving the hydromethanolic extract. Both extracts were kept at –18 °C until further studies.

Total phenolic content. The total phenolic content was determined by Folin-Ciocalteu method as previously described (7, 8).

DPPH radical scavenging activity. DPPH (1,1-diphenyl-2-picrylhydrazyl) radical scavenging activity was assessed according to Wangensteen *et al.* (7) except that the reaction time was 60 min. Quercetin was

used as positive control.

ABTS radical cation scavenging activity. ABTS [2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid)] radical cation scavenging activity was evaluated according to the method described by Re *et al.* (9). Scavenging activity was evaluated after 6 min. reaction time. Quercetin was the positive control.

Reducing power. The assay was performed using the method described by Ferreira *et al.* (10) with slight modifications. Quercetin was used as positive control.

Ferrous ion chelating activity. The ability to chelate ferrous ions was determined according to the method described by Venditti *et al.* (11) with minor changes. EDTA (ethylenediaminetetraacetic acid) was the positive control.

15-Lipoxygenase inhibition. The 15-lipoxygenase inhibitory effects of both extracts were evaluated as previously described (7, 12). Quercetin was used as positive control.

α-Glucosidase inhibition. The α-glucosidase inhibitory activity was determined according to Liu *et al.* (13). Acarbose was used as positive control.

Statistical analysis. All assays were performed in triplicate. The results were expressed as mean ± standard deviation. The EC_{50} values were calculated by linear interpolation between the values above and below 50% activity except the reducing power assay; in this assay, the EC_{50} values were the effective concentrations giving an absorbance of 0.5 (10).

RESULTS AND DISCUSSION

Fruiting bodies of *A. mellea* from Iasi region (Dobrovat forest) were evaluated for their total phenolic content, antioxidant and antihyperglycemic effects (*in vitro* studies). As the extraction solvent affects the phenolic content and consequently, the biological effects, the fruiting bodies were sequentially extracted with 96% ethanol and methanol:water mixture (1:1, v:v). The antioxidant potential of the extracts was assessed by testing their free radical scavenging, reducing and ferrous ion chelating abilities; besides, the capacity to inhibit 15-lipoxygenase was also tested. To evaluate the antihyperglycemic potential, the inhibition of α-glucosidase was measured.

Total phenolic content. Successive extraction of the mushroom material with 96% ethanol and methanol:water mixture (1:1, v:v) gave 9.75 g of ethanolic extract and 19.31 g of hydromethanolic extract (yields: 19.5% and 38.64%, respectively). The Folin-Ciocalteu assay showed a higher total phenolic content in the hydromethanolic extract in comparison with the ethanolic extract (21.68 ± 0.06 *vs.* 5.70 ± 0.28 mg/g).

DPPH radical scavenging activity. Both extracts scavenged DPPH radical in a dose-dependent manner. It is worthy to note that the hydromethanolic extract showed stronger scavenging effects than the ethanolic extract at all concentrations tested. At the highest concentration (833.34 μg/mL), the hydromethanolic extract exhibited 80.61 ± 0.28% scavenging activity while the ethanolic extract showed only 20.69 ± 0.20% activity (tab. I); higher concentrations of ethanolic extract could not be tested due to their low solubility in the reaction medium. The hydromethanolic extract scavenged DPPH radical with an EC_{50} value of 452.6 ± 2.7 μg/mL, considerably higher than the EC_{50} value determined for quercetin (2.33 ± 0.06 μg/mL).Vaz *et al.* reported EC_{50} values of 17.13 ± 0.67 and 3.95 ± 0.16 mg/mL for the ethanolic and

water soluble polysaccharidic fractions isolated from *A. mellea* samples from Bragança-Northeast Portugal (5).

ABTS radical cation scavenging activity. *A. mellea* extracts showed dose-dependent ABTS radical cation scavenging effects. At 250 µg/mL, the ethanolic extract exhibited only 18.31 ± 0.17% activity. Therefore, higher concentrations (500 and 1000 µg/mL) were tested for EC_{50} calculation. With regard to EC_{50} values, the hydromethanolic extract was 5.6 times more active than the ethanolic extract (140.57 ± 1.45 *vs.* 781.3 ± 16.6 µg/mL) (tab. II). Both extracts were less active than the positive control, quercetin (EC_{50} = 1 ± 0 µg/mL).

TABLE I

DPPH radical scavenging activity of *Armillaria mellea* extracts

Sample	Concentration (µg/mL)	Activity (%)	EC_{50} (µg/mL)
Ethanolic extract	104.17	6.44 ± 0.35	n.d.
	208.34	9.16 ± 0.13	
	416.67	13.36 ± 0.07	
	833.34	20.69 ± 0.20	
Hydromethanolic extract	104.17	15.28 ± 0.30	452.6 ± 2.7
	208.34	26.88 ± 0.09	
	416.67	45.85 ± 0.30	
	833.34	80.61 ± 0.28	

n.d. – not determined

TABLE II

ABTS radical cation scavenging activity of *Armillaria mellea* extracts

Sample	Concentration (µg/mL)	Activity (%)	EC_{50} (µg/mL)
Ethanolic extract	62.5	5.34 ± 0.16	781.3 ± 16.6
	125	10.17 ± 0.65	
	250	18.31 ± 0.17	
	500	41.63 ± 0.62	
	1000	54.43 ± 0.28	
Hydromethanolic extract	62.5	24.27 ± 0.40	140.57 ± 1.45
	125	44.09 ± 0.51	
	250	78.97 ± 0.54	

Reducing power. As in the previous studies, the hydromethanolic extract was more active; its reducing capacity ranged from 0.18 ± 0.00 at 36.36 µg/mL to 0.86 ± 0.00 at 218.18 µg/mL. In the same concentration range, the reducing power of the ethanolic extract was insignificant (data not shown). At 266.67 µg/mL, the ethanolic extract showed a reducing power of 0.17 ± 0.00 which increased to 0.53 ± 0.01 at 800 µg/mL. According to the EC_{50} values, the hydromethanolic extract was almost 6 times more active than the ethanolic one (129.45 ± 0.98 *vs.* 759.02 ± 5.71

μg/mL) (tab. III). The positive control, quercetin, showed a remarkable reducing capacity (EC_{50} = 2.98 ± 0.12 μg/mL). Vaz *et al.* determined EC_{50} values of 7.53 ± 0.10 and 0.98 ± 0.00 mg/mL for Portuguese *A. mellea* samples (ethanolic and water soluble polysaccharidic fractions, respectively) (5).

TABLE III
Reducing power of *Armillaria mellea* extracts

Sample	Concentration (μg/mL)	Activity	EC_{50} (μg/mL)
Ethanolic extract	266.67	0.17 ± 0.00	759.02 ± 5.71
	333.34	0.31 ± 0.00	
	466.67	0.38 ± 0.00	
	600	0.43 ± 0.00	
	733.34	0.48 ± 0.01	
	800	0.53 ± 0.01	
Hydromethanolic extract	36.36	0.18 ± 0.00	129.45 ± 0.98
	72.72	0.31 ± 0.00	
	145.44	0.55 ± 0.00	
	218.18	0.86 ± 0.00	

Ferrous ion chelating activity. Ferrous ion chelating capacity of both extracts increased with concentration. According to the results, the most active was the ethanolic extract (EC_{50} = 67.93 ± 0.35 μg/mL); its activity was almost 11 times lower in comparison with EDTA, which is a very efficient metal chelator (EC_{50} = 6.34 ± 0.06 μg/mL). The hydromethanolic extract chelated ferrous ions with a higher EC_{50} value (2 ± 0 mg/mL) suggesting a very low metal chelating capacity (tab. IV).

TABLE IV
Ferrous ion chelating activity of *Armillaria mellea* extracts

Sample	Concentration	Activity (%)	EC_{50}
Ethanolic extract	36*	36.41 ± 0.36	67.93 ± 0.35*
	72*	51.24 ± 0.10	
	144*	85.33 ± 0.10	
	288*	92.96 ± 0.22

	9.2**	96.90 ± 0.29	

* μg/mL; ** mg/mL

15-Lipoxygenase inhibition. Only the ethanolic extract showed the ability to inhibit 15-lipoxygenase. Its activity increased from 3.14 ± 0.25% at 83.34 μg/mL to 93.31

± 0.44% at 666.67 µg/mL showing an EC_{50} value of 290.93 ± 2.05 µg/mL (tab. V). In the same assay, quercetin (EC_{50} = 19.5 ± 0.7 µg/mL) showed a higher 15-lipoxygenase inhibitory activity than the ethanolic extract.

TABLE V

15-Lipoxygenase inhibitory activity of *Armillaria mellea* extracts

Sample	Concentration (µg/mL)	Activity (%)	EC_{50} (µg/mL)
Ethanolic extract	83.34	3.14 ± 0.25	290.93 ± 2.05
	166.67	15.29 ± 0.51	
	333.34	58.57 ± 0.44	
	500.00	85.87 ± 0.58	
	666.67	93.31 ± 0.44	
Hydromethanolic extract	inactive		

α-Glucosidase inhibition. The ethanolic extract showed a considerably higher α-glucosidase inhibitory activity than the hydromethanolic extract. At 16.67 µg/mL the ethanolic extract had 87.09 ± 0.14% inhibitory effect on α-glucosidase while the hydromethanolic extract exhibited only 5.38 ± 0.31% α-glucosidase inhibition at 833.34 µg/mL (tab. VI). It is worthy to note that the ethanolic extract (EC_{50} = 8.54 ± 0.06 µg/mL) showed a higher activity than the positive control, acarbose (EC_{50} = 70.7 ± 0.3 µg/mL).

TABLE VI

α-Glucosidase inhibitory activity of *Armillaria mellea* extracts

Sample	Concentration (µg/mL)	Activity (%)	EC_{50} (µg/mL)
Ethanolic extract	1.67	8.62 ± 0.03	8.54 ± 0.06
	8.34	48.66 ± 0.17	
	12.5	71.49 ± 0.23	
	16.67	87.09 ± 0.14	
Hydromethanolic extract	833.34	5.38 ± 0.31	n.d.

n.d. – not determined

The hydromethanolic extract was more efficient as free radical scavenger and reducing agent than the ethanolic extract. As the hydromethanolic extract contained almost 4 times more phenolic compounds, it is obvious that these constituents are mainly responsible for the higher free radical scavenging and reducing effects of the hydromethanolic extract. On the other hand, the ethanolic extract gave better results in the ferrous ion chelating, 15-lipoxygenase and α-glucosidase inhibition assays. Ferrous ions are strong pro-oxidants; they stimulate lipid peroxidation by different mechanisms (generation of hydroxyl radical *via* the Fenton reaction, decomposition of lipid hydroperoxides into radicals that propagate the chain reactions

such as peroxyl and alkoxyl radicals) (14). Therefore, ferrous ion chelation is an important mechanism in reducing oxidative stress. Lipid peroxidation is also mediated by 15-lipoxygenase; the enzyme catalyzes low density lipoproteins oxidation thus being involved in the pathogenesis of atherosclerosis (12). Besides these two antioxidant effects, the ethanolic extract showed a remarkable inhibitory activity on α-glucosidase, a carbohydrate hydrolysing enzyme; its activity was 8 times higher than that of acarbose, a well-known antidiabetic drug. It seems that other compounds than phenolics are involved in the ferrous ion chelating, 15-lipoxygenase and α-glucosidase inhibitory effects of ethanolic extract.

CONCLUSIONS

This study demonstrated that the hydromethanolic extract from *Armillaria mellea* fruiting bodies has higher free radical scavenging and reducing abilities than the ethanolic extract. The ethanolic extract is an effective ferrous ion chelator and inhibitor of 15-lipoxygenase and α-glucosidase. Overall, it can be concluded that *Armillaria mellea* fruiting bodies can be used in the development of products (dietary supplements, pharmaceutical products) with antioxidant, anti-atherosclerotique and antihyperglycemic (decrease of postprandial hyperglycemia) effects. It is obvious that further studies are needed to evaluate the *in vivo* relevance of *in vitro* activities.

GASTRORETENTIVE FLOATING SYSTEM CONTAINING ENALAPRIL MALEATE

Oral administration is the most convenient and preferred means of any drug delivery to the systematic circulation. Drugs that are easily absorbed from the gastrointestinal tract and have short half-lives are eliminated quickly from the systemic circulation. To avoid this limitation, the development of gastroretentive floating systems is an attempt to release and maintain an effective drug concentration in the systemic circulation for a long time. Floating systems are low-density systems that have sufficient buoyancy to float over the gastric contents and remain in the stomach for a prolonged period. While the system floats over the gastric contents, the drug is released slowly at the desired rate and reduces fluctuation in plasma drug concentration. Based on these aspects, a group of researchers from College of Pharmacy, Chikhli, India, prepared and evaluated the gastroretentive dosage form using enalapril maleate to increase oral bioavailability and increase gastric residence time. Enalapril maleate is an angiotensin-I converting enzyme inhibitor (ACE inhibitor) and is used in the treatment of hypertension and angina pectoris. The drug has an oral bioavailability of 40-60% possible due to narrow absorption window in the upper part of the small intestine. There were prepared eight formulations using different ratios of natural polymers by direct compression technique. Each tablet contained 20 mg of enalapril maleate, polymers and sodium bicarbonate, carbopol 934p, microcrystalline cellulose, magnesium stearate, talc, and had a total weight of 200 mg. There were used carrageenan and carbopol 934p because both have adhesive properties to the gastrointestinal wall. Xanthan gum (floating capacity) and guar gum (binder and gelling properties) were also used. The gastroretentive floating tablets were evaluated and analyzed according to the official method in Indian Pharmacopoeia. The gastroretentive floating tablet (enalapril maleate : carrageenan : carbopol 934p : xhanthan gum : guar gum : sodium bicarbonate : microcrystalline cellulose : magnesium stearate 20 : 23 : 2 : 23 : 23 : 4 : 99 : 99 : 3) had a floating time of more than 15 h; its floating lag time was found to be 69 s. The *in vitro* dissolution studies were carried out using USP apparatus type II at 50 rpm. Aliquots of dissolution medium (0.1 N HCl maintained at 37 ± 0.5°C) were withdrawn at predetermined intervals and the content of enalapril maleate was determined spectrophotometrically at 207 nm. Drug release was found to be 99.19 % (Nikan MS, Kale RH, Deshmane SV, Biyanik R. Preparation and evaluation of gastroretentive floating tablet containing Enalapril Maleate. *Int J Curr Pharm Res* 2014; 6 (3): 45-47)

THE EFFECTS OF MAGNESIUM NANOVESICLE FORMULATIONS ON SPATIAL MEMORY PERFORMANCE IN MICE (Abstract). **Aim:** The study investigates the effects of magnesium nanovesicles on the memory processes performance in mice. **Materials and methods:** L-a-phosphatidylcholine was used to obtain nano formulations as lipid vesicles systems stabilized thereafter with chitosan. The experiment was carried out on white Swiss mice, divided into 3 groups of 7 animals each, treated orally 7 consecutive days: Group I (Control): 0.1 mL/10g distilled water; Group II (Mg): 1 mmol/kbw magnesium chloride; Group III (Mg-vesicles): 1 mmol/kbw magnesium nanovesicles. The spatial memory performance was assessed by recording spontaneous alternation behavior in Y-maze test. Each animal was placed at the end of one arm and allowed to move freely through the maze during a single 8 min session. Alternation was defined as a consecutive entry in three different arms. The alternation percentage was computed according to the formula: (number of alternations/total number of arm visits – 2) x 100. Data were analyzed using *SPSS 17.0* software. Experimental protocols were implemented according to the recommendations of the University Committee for Research and Ethical Issues. **Results:** New carrier formulations entrapping magnesium chloride were designed: their mean size was 129.56 nm and the mean Zeta potential was +36.1 mV, indicating a moderate stability of the solution. Oral administration of magnesium vesicles resulted in a significant increase of spontaneous alternation percent in Y-maze test ($p<0.01$), which suggests an improvement of short-term memory. **Conclusions:** Using magnesium chloride entrapped in lipid vesicles induced an enhancement of cognitive functions in mice especially by facilitation of learning extinction. **Keywords:** MAGNESIUM, NANOVESICLES, MEMORY PERFORMANCE, COGNITIVE

Magnesium is one of the fourth main cations in the body (together with Ca^{2+}, Na^{+} and K^{+}), being the second most abundant intracellular cation after K^{+} (1, 2). It is involved in a various metabolic processes catalyzing more than 300 enzymatic reactions. One of the most important implications of this ion consists of modulation of the spinal cord and brain functions (3). Electrophysiology investigations

show that the activity of motor nerves carrying messages by electrical impulse from the brain to the muscles is mediated by the presence of magnesium (4, 5). Considerable evidence has been accumulated, definitely postulating that this cation is a significant factor in the brain's reactivity to metabolic and physiological stress (3). Magnesium ions (Mg^{2+}) possess a well-known depressant effect on the central nervous system and on neuromuscular transmission (5). Literature date reveals that the variation of intracellular magnesium concentration may represent a decisive aggression factor in acute and chronic disturbances in the central nervous system (2).

Nanoparticles consist of systems in size ranging from 10 to 1000 nm in which the active principle is dissolved, entrapped, encapsulated or attached. Among the carriers for active substances delivery, vesicles are self-assembled colloidal particles with broad application in modified drug-release from various pharmaceutical dosage forms (6).

Lipid nanovesicles are hollow spheres, commonly used to encapsulate labile hydrophilic molecules within their interior, and are important to be studied for developing new drug delivery carriers to facilitate the targeted delivery of active substances, to sustain drug effect in various tissues, to decrease its adverse effects (7). The advantages of using nanovesicles as drugs carriers are associated to their physicochemical properties, such as ultra small size, large surface area to mass ratio and high reactivity (8).

We aimed to investigate the effects of nanovesicles containing magnesium chloride on memory performances, after oral administration in mice.

MATERIAL AND METHODS

Materials: Substances were purchased from Sigma-Aldrich Company: the lipid used was egg yolk L-α-phosphatidylcholine (L-α-lecithin), approx. 99% pure; chitosan (N-deacetylation grade 79.7%, mean molecular weight M_w=310,000g/mol, polydispersity index = 3.26); magnesium chloride. The 0.5 (*w*/*w*) chitosan solutions were prepared in a 0.5 % (*v*/*v)* acetic acid. The other solutions were prepared in distilled water.

The soft matter vesicles were obtained after magnesium chloride immobilization inside lipid vesicles by dissolving the lipid in chloroform and removing the solvent by evaporation which lead to dry lipid film formation. The film was then hydrated by adding 12 mg/mL concentration of magnesium chloride aqueous solution. The obtained vesicles were stabilized afterwards with a 0.5% chitosan solution (9). The obtained nanovesicles containing magnesium were characterized using laser diffraction method with Shimadzu-SALD-7001 Laser Diffraction Particle Size Analyzer and Nikon E600 optical microscope. The present experiment was carried out on white Swiss mice (20-25 g), distributed into 3 groups of 7 animals each, treated orally (using an eso-gastric device), during 7 consecutive days, as follows: group 1 (Control): 0.1 mL/10 g body weight distilled water; group 2 (Mg): 1 mmol/kbw magnesium chloride; group 3 (Mg-vesicles): 1 mmol/kbw magnesium chloride entrapped in nanovesicles.

Methods: To evaluate the possible contribution of magnesium in maintenance of spatial cognition, the present study explored the effects of entrapped and non-entrapped magnesium on memory performances of mice in Y-maze test. This stand-

ardized model is used as a tool for investigation the neurobehavioral modifications of cognitive processes based upon spatial memory (10). The apparatus consists of 3 similar arms (40 x 9 x 16 cm) positioned at 120 degree from each others, and a central triangular area. Each arm has walls with specific designs all over the inner part allowing animals to differentiate it from the others. This experimental model was used to test if the mouse recognized the arm it had just explored and would consequently enter one of the other arms of the device (11).

Each animal was placed at the end of one arm and allowed to circulate freely through the maze during an 8 minutes session. The first 2 minutes were for habituation, and the last 6 minutes for the alternation between arms counted with photo beam breaks positioned at midpoint of each arm. Repeated activation of the same detector did not represent an arm-entry until the detector in another arm was activated (12).

Spontaneous alternation was considered as entry to an arm that was least occupied in recent times. Spontaneous percentage alternation was calculated as the ratio of actual to possible alternation (defined as the total number of arm entries minus two) multiplied by 100, according to the following formula: alternation % = number of alternations / total number of arm visits – 2) x 100 (13). Latency to leave the start arm, latency of first arm visit, number of arm visited, alternate arm returns, and the same arm returns were also registered. Supplementary, a video camera connected to a computer was used to allow us to record the animal behavior without distressing it. All trials were videotaped and analyzed by an independent observer. The experiments were performed between 08:00 and 13:00 a.m.

The obtained data were expressed as mean ± standard deviation (SD) in graphic charts. All values were analyzed using the ANOVA method implemented in *SPSS 17.0* software for Windows. P-value less than 0.05 were considered statistically significant compared to the Control group.

The experimental protocol was implemented following the recommendations of the "Grigore T. Popa" University Committee for Research and Ethical Issues guidelines for handling and use of experimental animals, according to the ethical standards of the European Community (14).

RESULTS

In a previous study we developed new carrier formulations that entrapped magnesium chloride in lipid vesicles with a moderate stability. The polymer chitosan binds to the vesicles forming a rigid bilayer decreasing the size of unilamellar systems.

The magnesium nanovesicles investigated were found to have a mean size of 129.56 nm and a mean zeta potential of +16.6mV. We appreciate that the systems correspond to the criteria of nanosuspensions and the presence of chitosan resulted in positively charged, more confined vesicles, generating repulsion forces, thus increasing stability.

In the behavioral model used (Y-maze test), spontaneous alternation or free-running represents the natural tendency of a laboratory animal to impulsively choose alternate arms.

Arm exploration was defined as entering at least the first third of an arm. The alternation percentage of control mice was 16.83 ± 0.75 (fig. 1).

Oral administration of magnesium-nanovesicles for 7 consecutive days resulted in an increase of arm entries number (mean ±SEM number of arm entries =

21.17±1.72), statistically significant compared to Control animals ($p<0.05$), relatively with a similar intensity compared to non-entrapped magnesium chloride (21.33±1.21) (tab. I, fig. 1).

In the Y-maze test spontaneous alternation represents the natural animal tendency to decide the arm in which to enter; spontaneous alternation observed for the Control group was 47.33±1.37.

The obtained results showed that the alternation percent of magnesium chloride in treated mice (59.50±1.05) was statistically higher than in Control rats ($p<0.05$), effect that corresponds to a facilitation of extinction learning in Y-maze test (fig. 2).

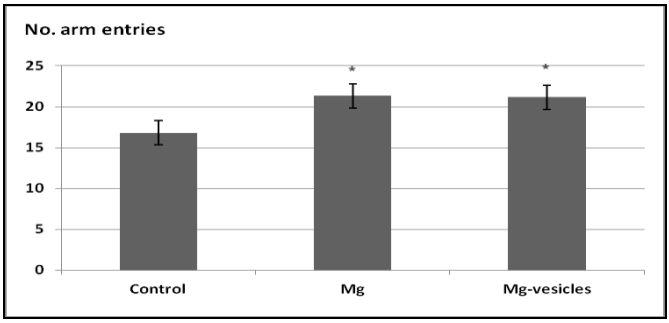

Fig 1. Effects of magnesium nanovesicles administration on the number of arm entries in Y-maze. Values were expressed as mean ± S.E.M of spontaneous alternation rate. *$p<0.05$ *vs.* control.

TABLE I

Variable dependent. Number of arm entries (Tukey HSD), (J) Substance: Control

(I) Substance	Mean Difference (I-J)	Std. Error	Sig.	95% Confidence Interval	
				Lower Bound	Upper Bound
MgCl2	.20000	.131	**.049***	.1148	.4016
MgCl2-vesicles	.25000	.142	**.044***	.1286	.4022

*mean difference is significant at the .05 level.

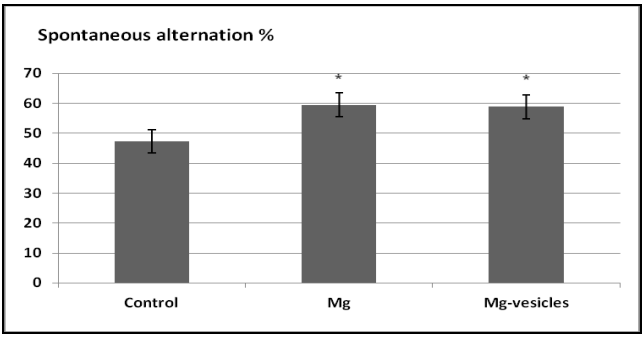

Fig 2. Effects of magnesium nanovesicles administration on spontaneous alternation percent in Y-maze. (values expressed as mean ± SEM of spontaneous alternation rate; *$p<0.05$ *vs.* Control).

TABLE II
Variable dependent. Spontaneous alternation %
(Tukey HSD), (J) Substance: Control

(I) Substance	Mean Difference (I-J)	Std. Error	Sig.	95% Confidence Interval	
				Lower Bound	Upper Bound
MgCl2	.35700	.121	**.038***	.2076	.4146
MgCl2-vesicles	.31500	.136	**.047***	.2112	.4114

* mean difference is significant at the .05 level.

The treatment with magnesium-nanovesicles during 7 consecutive days was associated with a statistically significant increase of spontaneous alternation percent (58.83 ± 2.32, $p<0.05$) compared to Control group, suggesting an improvement of short-term spatial memory. The effects of magnesium-nanovesicles were slightly less intense, but statistically non-significant than those of non-entrapped magnesium chloride (tab. II, fig. 2).

No modifications of exploration capacity were observed after administration of entrapped, non-entrapped magnesium chloride or saline.

Also, no significant changes were noticed neither of the latency of leaving the start arm, the latency of first arm visit, and the number of arm visited, alternate arm returns, nor in the same arm returns between groups treated with magnesium chloride, magnesium-nanovesicles and saline solution.

DISCUSSION

Literature reports limited studies about the use of magnesium chloride designed in nanovesicles (15).

Our work was focused on the integration of vesicles with a biopolymer as a route to create systems with increased stability. Using an original methodology we achieved the entrapment of magnesium chloride within the lipid vesicles stabilized with chitosan. Multiple studies on the biomedical use of chitosan as a drug carrier have been communicated; its physicochemical properties, such as intra- and intermolecular hydrogen bonding and cationic change in acidic medium makes the polymer appropriate for nanoparticulate system design.

Chitosan can persist longer in the gastrointestinal tract, being a suitable candidate for formulation of modified release drug delivery systems. It also can be cross-linked to different grades to modulate drug diffusion and consequently to realize prolonged release of the active substance (16).

Our experimental study proved that these new obtained formulations could be used as carriers for magnesium chloride in the organism.

Various experimental researches and clinical trials have revealed a strong correlation between the presence of stressful conditions, the blood level of magnesium and different pathological states such as anxiety and depression (17).

Also, several clinical studies have revealed low serum magnesium level in depressed patients. The results indicate that magnesium induces the antidepressant and anxiolytic-like effects without developing tolerance to these activities, which corresponds to a potential antidepressant and anxiolytic activity of magnesium in these disorders in humans. It has been suggested

that magnesium may be exerting its antidepressant effect through anxiolytic activity, and much more, a correlation between the severity of anxiety or depression and low plasma magnesium concentrations was observed (11).

It has been proved that magnesium deficiency increases susceptibility to different types of neurologic and psychological stressors in rodents and also in patients. Magnesium deficiency in laboratory animals was associated with a diminution of offensive aggressive manifestations, but with an increase of defensive aggressive behavior (2, 6). On the other hand, a lot of evidence suggests that the administration of magnesium proved a neuro-protective potential in different pathologic conditions, increasing learning capacity and enhancing the behavioral response to stimulants (1, 5, 14).

Some studies reveal that mice receiving a low magnesium diet for several weeks displayed increased immobility time in the forced swim test, indicating enhanced depression-like behavior. In addition, the partial magnesium-depletion increased anxiety-related behavior in the light/dark and open field test, while loco motor activity or motor coordination was not influenced. In the mouse magnesium induces an increase in motive agitation at low dose (100 mg/kg) and, on the contrary, a very clear reduction of this agitation at high dose (200 mg/kg). Experimental researches have proved that doses of 20 and 30 mg magnesium/kg were able to reduce immobility time in forced swim test exerting antidepressant-like activity (17). In the elevated plus-maze test, magnesium at the same doses produced an anxiolytic-like effect. The doses of magnesium active in both tests did not affect loco motor activity.

CONCLUSIONS

The present research indicates that oral administration during 7 consecutive days of soft magnesium nanovesicles was associated with enhancement of cognitive functions in mice. This was proved to be more efficient in facilitating extinction learning and a facilitation of short-term memory performances. The Y-maze test used to assess aspects of cognitive function and learning in rats showed an improvement of spatial memory in mice treated with magnesium chloride entrapped or non-entrapped in nanovesicles, indicated by an increase of spontaneous alternation rate compared to Control group, suggesting significant effects on short-term memory.

DIETARY POTASSIUM INTAKE AND RISK OF VASCULAR DISEASES

The presence of potassium in the daily diet has many benefits such as prevention of vascular disease, lowering blood pressure and reducing the risk of coronary disease. A recent study followed the relationship between a diet rich in potassium *versus* risk of stroke and death. The study group included 90,137 postmenopausal women, with or without hypertension, which ingested potassium-rich foods (average 2,611 mg potassium/day). The results showed that high dietary potassium intake lowers stroke risk and mortality. The risk of stroke was 12% lower in women with a diet rich in potassium, while the risk of death was 10% lower. Also, researchers found that the potassium-rich diet did not decreased stroke risk in postmenopausal women with hypertension, but has decreased mortality. These findings show that a diet rich in fruits and vegetables with high content of potassium (bananas, potatoes, tomatoes, leafy greens, white beans) can help to prevent vascular disease (Seth A, Mossavar-Rahmani Y, Kamensky V et al. Potassium intake and risk of stroke in women with hypertension and nonhypertension in the Women's Health Initiative. *Stroke*. 2014. DOI: 10.1161/STROKEAHA.114.006046).

POLYPHENOL-RICH EXTRACT FROM *PINUS SYLVESTRIS* L. BARK – CHEMICAL AND ANTITUMOR STUDIES (Abstract): *Pinus sylvestris* L. is a very important timber tree in Romania, the bark being the main waste from the wood processing. **Aim**: The aim of this study was to investigate the chemical composition and antitumor effects against HeLa cells of a polyphenol-rich extract from *Pinus sylvestris* L. bark. **Material and methods**: The polyphenolic content and profile were analyzed by means of spectrophotometry and RP-HPLC-UV/ESI-MS in the negative ion mode. The antitumor activity was investigated using two *in vitro* assays: MTT and flow cytometric apoptosis assays. **Results**: Pine bark extract contained a high total phenolic content (48.16±0.29%). RP-HPLC-UV/ESI-MS analysis allowed the identification of taxifolin, a taxifolin-hexoside and several procyanidins (two monomers, three dimers and three trimers). At 200 µg/mL, pine bark extract exhibited a high cytotoxicity against HeLa cells (82.10±1.95%). Flow cytometry revealed the ability of pine bark extract to induce apoptosis: 71.97±0.96% apoptotic cells were determined in HeLa cells after a 48 h incubation with pine bark extract (200 µg/mL). **Conclusions**: The ability of pine bark extract to reduce viability and induce apoptosis in HeLa cells suggests the presence of compounds with antitumor properties and encourages further studies for their isolation and characterization. **Keywords**: *PINUS SYLVESTRIS* L., RP-HPLC-UV/ESI-MS, CYTOTOXIC ACTIVITY, PRO-APOPTOTIC ACTIVITY

Besides its economic importance, *Pinus sylvestris* L. (Pinaceae, Scots pine) is used for therapeutic purposes; pine shoots, pine needle oil and purified turpentine oil are used in the inflammation of upper and lower respiratory tract as well as in rheumatic and neuralgic ailments (1). In Northern Europe *Pinus sylvestris* L. bark has been used for centuries both as food and folk medicine. In Sweden Sami people collected the inner bark and ate it fresh, dried or roasted (2). Recently, Scots pine bark extract was found to be a rich source of polyphenols with antioxidant and anti-inflammatory effects. Procyanidins from monomers through higher polymers and

other phenolic compounds (taxifolin, taxifolin-3'-*O*-β-D-glucoside, dihydro-coni feryl alcohol, pinoresinol, matairesinol, glucosides of *p*-hydroxybenzoic acid, vanillic and ferulic acids, vanillin, β-hydroxypropiovanillone) have been identified in Finnish Scots pine bark and phloem (3, 4). Extracts from Finnish Scots pine bark and phloem were also reported to inhibit lipid peroxidation, liposome and low-density lipoproteins oxidation and the production of inflammatory mediators nitric oxide and prostaglandin E_2 (4, 5, 6).

Pinus sylvestris L. is a very important timber tree in Romania, the bark being the main waste from the wood processing. A literature survey showed no studies on the chemical composition and possible biological effects of bark extracts from trees growing in Romania. The aim of this study was to investigate the phenolic content and profile and antitumor effects against HeLa cells (cervical adenocarcinoma) of a polyphenol-rich extract from the bark of a mature Scots pine tree growing in Calimani Mountains (Romania). This study is part of a larger, extensive research aiming to explore strategies for the therapeutic valorization of conifer bark wastes.

MATERIAL AND METHODS

Plant material. *Pinus sylvestris* L. bark was collected in Calimani Mountains (Romania) on February 20, 2008. Patches of bark were removed from a mature Scots pine tree which was randomly selected. The species was identified by specialists from *Anastasie Fatu* Botanical Garden, Iasi, Romania. The bark was shade-dried at room temperature for two weeks and powdered in a knife mill. A herbarium voucher sample is deposited in the Discipline of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy *Grigore T. Popa*-Iasi, Romania.

Materials. All reagents and solvents were of analytical grade.

Extraction. Pine bark powder (150 g) was extracted with 3 × 1500 mL of 80% methanol using a magnetic stirrer, each time for 3 h. The combined extracts were taken to dryness by evaporation under reduced pressure followed by lyophilization resulting in 26.03 g of raw extract (yield: 17.35%). The extract was stored at -20ºC until used.

Total phenolic content. Total phenolic content was determined by Folin-Ciocalteu method (7). The result was expressed as g of gallic acid equivalents (GAE) in 100 g extract.

RP-HPLC analysis. Reversed-phase high performace liquid chromatography (RP-HPLC) analysis was conducted on a Perkin-Elmer liquid chromatograph consisting of a SCIEX API 365 LC/MS/MS mass spectrometer connected to a Series 200 HPLC system with UV/VIS detector and Analyst Software 1.1 data system. RP-HPLC coupled with electrospray ionization-mass spectrometric detection (ESI-MS) in the negative ion mode was carried out using the method of Karonen et al. (2) with slight modifications. Separations were done on a Merck Superspher 100 RP-18 column (75 mm×4 mm, i.d. 4 μm). The mobile phase consisted of (A) acetonitrile and (B) water and formic acid (99:1, v/v). The elution profile was: 100% B (0-3 min, isocratic); 0-30% A in B (3-30 min, linear gradient); 30-70% A in B (30-33 min, linear gradient); 70% A in B (33-42 min, isocratic); 70-0% A in B (42-45 min, linear gradient); 100% B (45-60 min, isocratic). The flow rate was 1 mL/min. The detection wavelength was set at 280 nm.

MTT assay. MTT [3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide] assay was performed according to Mosman (8) after a 48 h incubation of pine bark extract (50-200 μg/mL) with HeLa cells. Etoposide (200 μg/mL) was the positive control.

Flow cytometric apoptosis assay. The effects on apoptosis were evaluated using a Cell Lab Quanta TM SC MPL flow cytometer (Beckman Coulter, Fullerton, USA). Two fluorochromes were used to identify live, dead, apoptotic and pre-apoptotic cells: annexin V conjugated with fluorescein isothiocyanate (FITC) and propidium iodide (PI). Annexin V binds to phosphatidylserine which moves from the inner leaflet of plasma membrane to the outer leaflet in apoptotic and pre-apoptotic cells. Conjugation with FITC increases annexin V affinity for the membrane. PI is used to distinguish live cells from dead cells: it penetrates only the membrane of dead cells and binds to DNA. The assay was performed after a 48 h incubation of HeLa cells with pine bark extract (100 and 200 μg/mL). Etoposide (200 μg/mL) was used as positive control. Data analysis was performed with Flowing Software (Cell Imaging Core, Turku Center for Biotechnology, Åbo Akademi University, Finland) (9, 10).

Statistics. All analyses were carried out in triplicate. Results were expressed as mean ± SE.

RESULTS AND DISCUSSION

Phenolic content and profile. Spectrophotometric quantification showed a high phenolic content (48.16±0.29 g% GAE) in pine bark extract (PBE). Main polyphenolic constituents in PBE were identified on the basis of their MS fragmentation pattern, namely characteristic deprotonated molecules and fragment ions which were compared with those mentioned in literature (2, 3). A taxifolin-hexoside, taxifolin and procyanidins (two monomers, three dimers and three trimers) were identified as major polyphenols in PBE. The mass spectrum of taxifolin-hexoside (retention time=17.39 min) showed $[M-H]^-$ and $[2M-H]^-$ deprotonated molecules at *m/z* 465.2 and 931.5 together with two fragment ions: $[A]^-$ fragment ion at *m/z* 302.8 corresponding to the deprotonated aglycone part of taxifolin-hexoside and $[A-H_2O]^-$ fragment ion at *m/z* 284.8. Several taxifolin-*O*- and *C*-glucosides have been isolated from different species (Finnish Scots pine, *Chamaecyparis obtusa* (Siebold & Zucc.) Endl., *Smilax glabra* Roxb., *Agrimonia pilosa* Ledeb., *Polygonum orientale* L., *Garcinia epunctata* Stapf) (4, 5, 11, 12). In our study, the identity of the hexose could not be established. In case of glycosides, ESI-MS analysis allows only the identification of the aglycone and the class of carbohydrates (hexose, pentose) the components of the sugar chain belong to; it cannot provide information on the identity of the hexose or position of aglycone-sugar linkage. The mass spectrum of taxifolin (retention time=17.62 min) showed $[M-H]^-$ and $[2M-H]^-$ deprotonated molecules at *m/z* 302.9 and 607.3 and $[M-H_2O]^-$ fragment ion at *m/z* 284.8. The fragmentation pattern of taxifolin is in agreement with MS spectral data reported by Karonen et al. (2, 3). In addition, $[M-H]^-$ deprotonated molecules of well separated procyanidin peaks corresponding to monomer (*m/z* 289.0), dimer (*m/z* 577.3) and trimer (*m/z* 865.3) structures were detected. In each spectrum, additional $[2M-H]^-$ deprotonated molecules and/or fragment ions were also detected. Two monomers were identified on the basis

of their specific MS fragmentation pattern: $[M-H]^-$ and $[2M-H]^-$ deprotonated molecules at *m/z* 289.0 and 579.4 and a fragment ion at *m/z* 245.1 generated by the loss of a hydroxyethylene moiety from $[M-H]^-$ at *m/z* 289.0. According to literature data, (+)-catechin (retention time=13.09 min), having a *2R,3S*-stereochemistry, elutes earlier than (-)-epicatechin (retention time=13.41 min), having a *2R,3R*-stereochemistry (3). Three dimers (retention times=12.29, 12.81 and 16.97 min) and three trimers (retention times=13.61, 13.89 and 16.27 min) were also identified. Isomeric dimers had similar fragmentation patterns. The mass spectrum of a dimer (RT=12.81 min) consisted of $[M-H]^-$ and $[2M-H]^-$ deprotonated molecules at *m/z* 577.3 and 1155.5 and fragment ions formed through quinone methide cleavage of the interflavonoid bond (*m/z* 286.9, *m/z* 289.0), retro-Diels-Alder fragmentation (*m/z* 425.3), sequential elimination of water from *m/z* 425.3 (*m/z* 407.4) and heterocyclic ring fission (*m/z* 451.1). Similar mass spectra were obtained for isomeric trimers. For example, a trimer (RT=13.61 min) exhibited a very abundant $[M-H]^-$ deprotonated molecule at *m/z* 865.3 and fragment ions indicating quinone methide cleavage of the upper interflavonoid bond (*m/z* 286.8, 577.2), retro-Diels-Alder fragmentation (*m/z* 713.6), heterocyclic ring fission (*m/z* 739.4) and further retro-Diels-Alder fragmentation of *m/z* 577.2 (*m/z* 425.3). Mass spectral data of the major polyphenolic constituents in PBE are shown in tab. I. An unresolved hump corresponding to procyanidin polymers eluted between 20 and 30 min (fig. 1).

MTT assay. PBE reduced the viability of HeLa cells in a concentration-dependent manner. At 200 μg/mL, PBE (82.10± 1.95%) exerted a cytotoxicity comparable to that of etoposide (87.16±2.72%) (tab. II).

TABLE II

Cytotoxic activity of pine bark extract (PBE) against HeLa cells (MTT assay)

PBE (μg/mL)	**Cytotoxic activity** (%)
50	27.92 ± 6.00*
100	61.99 ± 1.40**
200	82.10 ± 1.95**
Etoposide (μg/mL)	**Cytotoxic activity** (%)
200	87.16 ± 2.72**

(*p < 0.01; **p < 0.001)

Flow cytometric apoptosis assay. Defective apoptosis is a major cause in the development and progression of cancer. As apoptosis is down-regulated in cancer cells, identification of drugs having the ability to induce apoptosis is a very promising treatment option in antitumor therapy as such drugs will selectively affect tumor cells (13). At both concentrations tested (100 and 200 μg/mL), PBE significantly increased the percentage of apoptotic cells to 70.17±8.11% and 71.97±0.96%, respectively in comparison with the control (3.18±0.56%). The percentage of apoptotic cells reached only 41.00±3.02% under treatment with etoposide (200 μg/mL) (tab. III). Etoposide is a well-known apoptosis-inducing agent; its activity is based on caspase activation and nuclear fragmentation (14).

TABLE III

Effects of pine bark extract (PBE) on apoptosis in HeLa cells

	Cells (%)			
	Live	**Dead**	**Apoptotic**	**Pre-apoptotic**
Control	91.70 ± 3.23	4.61 ± 0.77	3.18 ± 0.56	0.51 ± 0.01

Taxifolin and procyanidins might be partially responsible for the cytotoxic and pro-apoptotic effects of PBE. Taxifolin has been reported to inhibit the proliferation of human cervical cancer HeLa cells; the antiproliferative activity is mainly based on inducing apoptosis by upregulating the expression of pro-apoptotic proteins p53 and p21. Procyanidin extract from *Pinus koraiensis* bark inhibited the growth of HeLa cells by increasing the expression of pro-apoptotic protein Bax and reducing the expression of anti-apoptotic proteins Bcl-2 and survivin (15). Besides taxifolin and procyanidins, other compounds might be also involved in the antitumor activity of PBE. Conifer barks contain a large variety of phytochemicals including polyphenols, terpenes, resinic acids, fatty acids, free or esterified alcohols. It is worthy to note that certain serratane-type triterpenes, resinic acids and their derivatives were reported to reduce the tumor-promoting potential of 7,12-dimethyl-benzanthracene and 12-*O*-tetradecanoylphorbol-13-acetate. Monoterpenes, lanostane and serratane-type triterpenes isolated from *Abies* and *Pinus* species showed antiproliferative effects in different human tumor cell lines: A549 (alveolar adenocarcinoma), COLO 205 (colon adenocarcinoma), QGY-7703 (hepatocellular carcinoma) and THP-1 (monocytic leukemia) (16-18). In view of these literature data, it is obvious that extensive chemical studies are to be done for the identification and isolation of antitumor compounds in PBE.

CONCLUSIONS

The polyphenol-rich extract from *Pinus sylvestris* L. bark effectively reduced viability and induced apoptosis in human cervical cancer HeLa cells. Our findings clearly show that pine bark extract is a good candidate for the isolation of compounds with apoptosis-inducing effects.

ACKNOWLEDGEMENTS

This work was partially supported by the Cyprus Research Promotion Foundation (CRPF grant KY-POY/0407/03) and the National Authority for Scientific Research in Romania (Bilateral Cooperation 311/2009). The authors are grateful to Prof. dr. Juha-Pekka Salminen and Dr. Maarit Karonen (Department of Chemistry, University of Turku) for their support in performing and interpretation of HPLC-ESI-MS analysis.

LAUDATIO

UNIVERSITY PROFESSOR DOCTOR EMANOIL GRIGORESCU AT 90 YEARS

Prof. Dr. Emanoil Grigorescu is an outstanding personality with remarkable scientific achievements in the field of medicinal plants, one of the foremost exponents of the Romanian School of Pharmacognosy.

Prof. Dr. Emanoil Grigorescu was born on the 10th of May 1923 in Oltenita (Ilfov county). He has graduated from the Faculty of Pharmacy, Institute of Medicine and Pharmacy in Bucharest in 1948. Additionally, he was a student of the Faculty of Sciences, Physical – Chemistry section which he graduated in 1947 (without state examination). In 1964 Prof. Dr. Emanoil Grigorescu defended his Ph.D. thesis *Contributions to the pharmacognostic and phytochemical study of indigenous Hippophaë rhamnoides L.*, initially supervised by Prof. Dr. Elemér Kopp and then by Prof. Dr. Teodor Goina.

Prof. Dr. Emanoil Grigorescu started his academic didactic career after his university graduation. Between 1948-1953 he was trainer and then assistant in the Department of Biochemistry, Faculty of Pharmacy, Institute of Medicine and Pharmacy in Bucharest. In October 1953 he started his work as an assistant in the Department of Pharmacognosy. Ten years later, in 1963, he became lecturer in the same department. Meanwhile, he served as scientific secretary (July 1961-February 1963) and deputy scientific director (February-October 1963) in the Institute for State Control of Drugs and Pharmaceutical Research. In October 1963, lecturer Emanoil Grigorescu was appointed substitute associate professor in the Department of Pharmacognosy of the Institute of Medicine and Pharmacy in Iasi. The most prolific years in his didactic and research career were the years spent in this department. In 1965 he became associate professor and three years later, professor and Ph.D. advisor. Between 1993-1997 he was consulting professor. He was also involved in administrative activities being vice dean (February-October 1965) and dean (October 1965-February 1975) of the Faculty of Pharmacy.

Prof. Dr. Emanoil Grigorescu had a fruitful scientific activity focused on the valorization of medicinal plants used in traditional medicine, scientific justification of traditional uses of medicinal plants and identification of new medicinal plants with potential therapeutic uses. He studied with passion and tenacity not only indigenous medicinal plants, but also plants used in the traditional medicine in several African and Asian countries. The list of studied species is so long that it covers almost all letters in the alphabet starting with *Aesculus hippocastanum* and ending with *Withania somnifera*. Prof. Dr. Emanoil Grigorescu was interested not only in the isolation and chemical characterization of phytochemicals from different plants, but also in the possibility of using phytochemicals in the semi/synthesis of new drugs. His investigations have led to the isolation and characterization of isorhamnetin, malvidin, narco-

tine, rheadine, galanthamine, reserpine, berberine, ursolic and oleanolic acids, beta-sitosterol, usnic acid and different polysaccharides. He intensively collaborated with colleagues from the chemistry departments to develop new drugs from phytochemicals. This collaboration led to the development of several new semisynthetic derivatives with higher bioavailability such as rutin-cysteine, rutin-ε aminocaproic acid, berberine-ε aminocaproic acid and podophyllotoxin-tryptophan complexes. In addition to phytochemistry, Prof. Dr. Emanoil Grigorescu approached other areas of research. He studied the biosynthesis of certain phytochemicals (antraquinones, coumarins, anthocyanidins, carotenoids, thioglycosides, lisergic alkaloids) using *in vitro* tissue cultures. He developed phytobiological methods as a preliminary step for toxicity evaluation before animal testing. His innovative research is materialized in more than 200 published works, 12 original drugs in microproduction (Rutin-S, Stomadex, Septazulen, Hipotens, Cerebrodil, Bilogal, Lactoflux), 7 original drugs in industrial production (Variterp, Rutin-S, Perasin, Plavobil, Plavocorona) and 56 patents. He was awarded three times by the Romanian Ministry of Education and Teaching (1963, 1968, 1971). In 1991 he was awarded the Title of Elite Inventor class IV. The research activity of Prof. Dr. Emanoil Grigorescu is undoubtedly a reference point for the young researchers in the fields of pharmacognosy, phytochemistry, phytotherapy and plant biology.

Prof. Dr. Emanoil Grigorescu supervised the activity of 14 Romanian and 5 foreign Ph.D. students. He has authored and coauthored several books in the field of medicinal plants: *Din ierburi s-au născut medicamentele* (*Drugs derived from plants*, Ed. Albatros, Bucharest, 1984); *Burundi: oameni, fapte, locuri* (*Burundi: people, deeds, places*, Ed. Albatros, Bucharest, 1984); *Index fitoterapeutic* (*Phytotherapeutic index*) in collaboration with Prof. Dr. Ursula Stănescu and Prof. dr. Ioan Ciulei (Ed. Medicală, Bucharest, 1986); *Plante medicinale, fitochimie şi fitoterapie* (*Medicinal plants, phyto-chemistry and phytotherapy*) in collaboration with Prof. dr. Ioan Ciulei and Prof. Dr. Ursula Stănescu (Ed. Medicală, Bucharest, 1993); *De la etnomedicină la fitoterapie – tezaurul verde al medicinei* (*From ethnomedicine to phytotherapy – the green treasure of medicine*) in collaboration with Pharm. Dr. Felix Silva (Ed. Spiru Haret, 1997); *Strămoşii plantelor medicinale – legende pierdute* (*The ancestors of medicinal plants – lost legends*, Ed. Cantes, 1998); *Index fitoterapeutic* (*Phyto-therapeutic index*) in collaboration with Prof. dr. Mihai Ioan Lazăr, Prof. dr. Ursula Stănescu, Prof. dr. Ioan Ciulei (Ed. Cantes, 2001). *Plante medicinale, fitochimie şi fitoterapie* has received the Iuliu Hatieganu Award of the Romanian Academy in 1993.

It is noteworthy that in 1979 Prof. Dr. Emanoil Grigorescu became United Nations Organisation (UNO) expert for medicinal plants. As UNO expert he took part in the organisation of three UNIDO (United Nations Industrial Development Organization) international courses partly held in the Department of Pharmacognosy in Iasi. He participated in two UNIDO missions in Burundi (1979) and Rwanda (1984). Later, scientists from Burundi, Rwanda and Yugoslavia were trained in the Department of Pharmacognosy under the supervision of Prof. Dr. Emanoil Grigorescu.

Prof. Dr. Emanoil Grigorescu was president of Section of Pharmacy of the Society

of Physicians and Naturalists, Iasi (1968-1975), Commission of Medicinal Plants in the Association of Scientists Iasi (since 1990) and Romanian Society of Phytotherapy (since 1993). He was member (1976-1990) and then vicepresident (since 1990) of the Commission of Medicinal Plants of the Romanian Academy and member in several professional and scientific commissions (Medicinal Plants Commission for Elaboration of the Romanian Pharmacopoeia, Drug and Pharmacovigilance Commission, Research Commission for the Valorization of Medicinal and Aromatic Plants, Medicinal Plants Commission of the International Federation of Pharmacy). In recognition of his outstanding merits, in 1991 Prof. Dr. Emanoil Grigorescu became member of the Academy of Medical Sciences.

Prof. Dr. Emanoil Grigorescu built his impressive didactic and scientific career on extensive work, dedication and passion. At his 90th anniversary we wish him a long life in good health.

2. Faculty of Pharmacy

CONTRIBUTIONS TO THE PHYTOCHEMICAL STUDY OF *BIDENS TRIPARTITAE HERBA* FROM ROMANIA. I.TANNINS (Abstract): **Aim:** To analyze qualitatively and quantitatively tannins in the native plant, collected during the whole vegetation period from different areas of the country, and in its different organs (flower, stem, leaf). **Material and methods**: For quantitative analysis, the plant product was extracted by repeated maceration (3 days) with 80% methanol. Proanthocyanidins in the extract were quantified by spectrophotometric methods. **Results**: condensed tannins were present while hydrolyzed tannins were absent. Chromatographic analysis showed that tannins spectrum is similar in all plant organs and in plants collected at different times throughout the vegetation period. The differences are only quantitative. The maximum amount of tannins was found during the flowering stage (10.32%). **Conclusions**: In terms of tannin content, flowering is the best time to collect. However, collection throughout the whole vegetation period is acceptable. **Keywords:** MEDICINAL PLANTS, *BIDENS TRIPARTITA L.*, TANNIN.

Bidenstripartita L. (family *Asteraceae*), usually named Burr marigold and Water agrimony, is an erect annual plant, growing 15 to 100 cm high. (1, 2, 3, 4, 5, 6).

The plant is known and used since ancient times, especially for treatment of dermal diseases and wound healing (2). In popular medicine, it is orally administered as a diuretic, diaphoretic, febrifuge, antidiarrhoeal, antiallergic, anti-inflammatory, anthelminthic, choleretic and as a kidney tonic (1, 5, 6, 7). All these effects were confirmed by pharmacological tests or clinical studies. Moreover, good results have been reported in treating chronic dysentery, acute and chronic enteritis, ulcerative colitis, bladder and kidney problems and some forms of cancer (1, 8).

The chemical composition is not well studied. Some authors even specify this. In the last URSS pharmacopoeia the product is standardized according to polyholosides, but their presence does not account for all therapeutic properties of the plant.

It is known that the dried aerial parts contain: flavones (luteolin, cynaroside), tannins, polyacetylenes, coumarins (umbelliferone, scopoletin and aesculetin), 0.05-0.11% essential oil (eugenol, ocimene and cosmene), 4.51-4.65% saccharides (arabinose, galactose, glucose, rhamnose and xylose), organic acids, carotene, vitamin C and microelements (manganese) (1, 3, 4, 8, 9).

In the literature we found almost noth-

ing about tannins in this plant. Considering the therapeutic properties of tannins (astringent, anti-inflammatory, antioxidant, anti-microbial and others) we can presume that they are extremely important components responsible for the numerous therapeutic uses of the product *Bidenstripartitaeherba*.

Also unknown is the best time for collecting the plant material. Some authors recommend the period of flowering, others budding and/or flowering (1, 3), or just budding (5, 6, 9). Some of them admit the later collection, but only the side branches, with flower buds (10), others are very strict about insisting that the product collected after the beginning of flowering has no curative properties (4).

For this reason, we decided to collect the native plant during the whole vegetation period in different regions of the country. Our aim wasto study tannins qualitatively and quantitatively in the collected plant material, and their content in different plant organs (flower, stem, leaf).

MATERIAL AND METHODS

The vegetative material originated from Iasi area and Ceahlau massif and was collected in the summer of year 2012, from late June to early October, for approximately equal time periods (10-15 days). The collection was made at different times during the afternoon. The plant was identified based on macro- and microscopic characters (1, 3) and dried in our laboratory.

For the qualitative analysis the air-dried samples of raw plant material were cut into 2-3 mm particles and then extracted using water: 5 g of dried herb was extracted with 100.0 ml boiling water on water bath for 15-20 min. The obtained extract was filtered through filter paper and was used to carry out tannins specific qualitative reactions (11, 12).

For the TLC analysis we chose some more representative samples. We prepared a 1:10 ethanolic extract for each analyzed sample. The extracts were subjected to chromatographic separation.

From each sample 10 µl of extractive solution was spotted on the chromatographic plate. The working conditions are:

- stationary phase - Silica gel G F_{254}-precoated TLC plates (Merck, Germany);
- mobile phase: n-buthanol / glacial acetic acid / water (40 / 12 / 28, v/v/v);
- detection: spaying with 1% vanillin in concentrated HCl (12).

For quantitative analysis, 2 g of crushed plant material taken from each sample has been extracted by repeated maceration method (3 days) with 25 ml of 80% methanol. For comparison, a sample extraction was performed by repeated maceration and stirring (magnetic stirrer).The crushed product was extracted with 3 equal portions of 80% methanol in 3 one-hour cycles.

Hydrolysis of proanthocyanidin was performed as described by Porter et al. (13, 14). The iron reagent was a 2% (w/v) solution of $NH_4Fe(SO_4)_2 \cdot 12H_2O$ in 2M HCl. 0.5 ml of analyzed extract, 3.0 ml of n-butanol solution and conc. HCl (95:5 v/v) and 0.1 ml of iron reagent were added to the glass tube sealed with a cap. The reaction mixture was then heated for 1 h at 95^0C on water bath and then red at 550 nm in a 10 mm lath-length glass cell.

The results were expressed as milligrams of cyanidin equivalents per gram of extract using ε = 17,360 L mol-1 cm-1 and MW = 287.24 (15).

RESULTS

The results of qualitative reactions for the

tannins: with lead acetate-precipitate (tannins), with basic zinc acetate-green precipitate (tannins), with $FeCl_3$soln-green precipitate (condensed tannins), with iron alum-dark green precipitate (condensed tannins), with styassny reagent-red precipitate (condensed tannins), filtrate gave no precipitate with iron alum (no hydrolysable tannins).

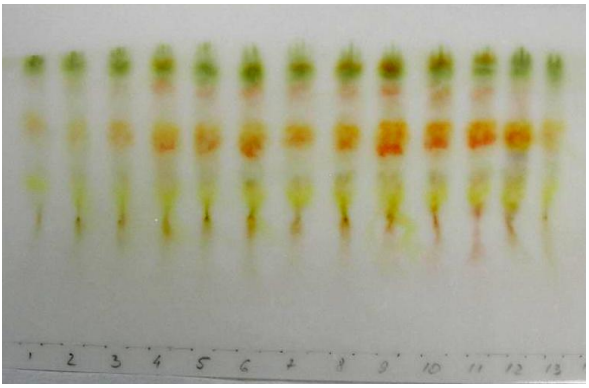

Fig. 1. Chromatogram for tannins during the vegetation period. Sample numbers correspond to those in tab. I.

DISCUSSION

From the results of qualitative reactions (tab.I) we conclude that in this plant product the condensed tannins are present while hydrolysed tannins are missing. This confirms the results of thin layer chromatography. Moreover, chromatographic analysis showed that tannins spectrum is similar in all plant organs and in plants collected at different times throughout the vegetation season. The differences are only quantitative (fig. 2,3).

Samples 4, 5 and 6 were collected on the same day (afternoon of July 23), from the same area but in locations with different environmental conditions. Sample 4 was collected from the banks of dried up pond. Plants were small size (about 25 cm), highly pigmented and at an advanced stage of development. Many specimens were in fruiting stage (we did not collect them because of indications in the literature on optimal collection period). Samples 5 and 6 were collected from an area intensively irrigated by a creek. Sample 5 had a reduced pigmentation, while sample 6 was heavily pigmented. The determinations showed that sample 5 is less rich in tannins than the other two samples. Sample 7 also included some plants in budding and flowering stage. Samples 8 and 9 were collected on two consecutive days. Sample 8 was collected from a wetland, partially shaded on the banks of Bahluiriver (altitude less than 100 m above sea level). Sample 9 was collected from Ceahlau massif (approx. altitude 800 m). Due to drastic reduction of flow and stream channels narrowing, some plants grew on rocky soil, exposed to direct sun light and away from water. Sample 9 was obviously richer in tannins. This is probably accounted for by altitude, but other factors that might influence the biosynthesis of tannins should not be ignored. Samples 10 and 11 were collected on the same day and location. Sample 10 included only flowering plants. Sample 11 included only the plants with fruits. Sample 10 contained the highest amount of tannins of all samples. Although Sample 11 contained less tannins, it exceeded the average for all study samples. This finding allows us

to conclude that the opinion according to which after flowering the plant should not be collected is unfounded, at least in terms of tannin concentration.

Sample 12 included only leaves, the other parts being removed because most of the collected plants had lignified stems. These are not usually used for the preparation of a drug. Results fit, however, to the levels of evidence with the lowest concentrations. So it is possible to even use them.

Sample 13 is similar to sample 2, but extracted by shaking with slight heating magnetic stirrer. The results are very close. We chose the classic repeated maceration because it was easier to implement.

The differences in concentration might be due to the fact that we collected samples from different areas around Iasi with different habitat conditions. It is known, for example, that tannins biogenesis is dependent on the intensity of photosynthesis (11). This happened because the populations of previously collected plants were destroyed by human activities.

CONCLUSIONS

The *Bidenstripartitaeherba* plant product contains condensed tannins.

The average concentration throughout the vegetation period is 5.77%.

Tannins are present in all plant organs. The highest amount was found in the leaves, the lowest in the stem. During the vegetation period the highest amount of tannins was at flowering. In terms of tannin content flowering is the best time to collect.

Somewhat lower values were found throughout the vegetation period, fruiting period included. Thus, the collection throughout the vegetation period may be acceptable.

The obtained results allow us to conclude that water deficit increases the concentration of tannins. We also found that heavily pigmented specimens contain a larger amount of tannins. Plants collected at high altitudes were also rich in tannins, but they were collected from drier places and were intensely pigmented.

NEWS

EPOTHILONE A AND EPOTHILONE B, PROMISING SUBSTANCES FOR TREATMENT OF HUMAN OVARIAN CANCER

Epothilones, a class of microtubule-targeting agents, are secondary metabolites of myxobacteria. A new study on epothilone A and epothilone B showed that they could be good candidates for ovarian cancer treatment. Epothilones have a taxane-like mechanism of action, but are more effective against P-glycoprotein overexpressing cancer cells. The effects of epothilone A and epothilone B, obtained from myxobacterium Sorangium cellulosum, were investigated on SKOV-3 human ovarian carcinoma cell line and the results were compared with those of paclitaxel. The study demonstrated that epothilone A and epothilone B had higher cytotoxic effects (IC50 = 20.4 nM and 57.5 nM, respectively) than paclitaxel (IC50 = 126.2 nM) in MTT assay. In addition, they induced apoptosis in ovarian carcinoma cell line through reactive oxygen species (ROS) production. This could be considered one of the mechanisms involved in epothilones cytotoxicity. The oxidative stress caused by ROS determine disruption of mitochondrial membrane function and has as consequence the induction of apoptosis. The results showed that epothilone A and epothilone B caused greater depolarization of the mitochondrial membrane than paclitaxel. Preliminary data of this study indicate that epothilone A and epothilone B can be used in the near future in ovarian cancer treatment with better results than those of paclitaxel (Rogalska A, Marczak A, Gajek A et al. Induction of apoptosis in human ovarian cancer cells by new anticancer compounds, epothilone A and B. Toxicol in Vitro 2013; 27: 239-249).

VALUE OF SCOTS INDEX IN A IASI TOWN SCHOOL COMMUNITY (Abstract): The SCOTS version of the Developmental Defects of Enamel Index was designed for use in field settings as an add-on to caries prevalence examinations in order to monitor prevalence of enamel defects. **Aim:** The aim of this study was to determine the prevalence of developmental dental anomalies (DDE) using the SCOTS index and to statistically analyze the distribution of these anomalies. **Material and methods:** The study included 240 children aged 7-10 years old, from Iasi, Romania. DDE have been evaluated using SCOTS index. **Results:** DDE prevalence was 9.2% with the highest rate represented by diffuse opacities (SCOTS score 2), followed by demarcated opacities and hypoplasia (SCOTS scores 1 and 3). Most affected were the male children. 61.9% of all affected teeth had an extension defect of less than 1/3 of the tooth surface and 66.7% of lesions were asymmetrical. There was not a statistically significant correlation between the SCOTS score value and children age or sex. Socio-economic status can be a potential risk factor for DDE. **Conclusions:** DDE prevalence was quite low compared with other studies. SCOTS index is suitable for epidemiological screenings and highlights the public health significance of DDE. **Keywords:** CHILDREN, DEVELOPMENTAL DEFECTS ENAMEL (DDE), SCOTS INDEX.

Despite the relatively low incidence in child oral pathology, developmental defects of enamel (DDE) trigger a special concern, attested by the considerable amount of papers in specialized literature as well as the numerous studies in recent years.

SCOTS index is a modified version of the DDE index and was designed for use in field evaluations as an add-on to caries prevalence examinations in order to monitor prevalence of enamel defects. It was proposed by Davies and Pitts in 1990 - '91 initially for Scottish Health Board, and used in studies conducted under time pressure and poor equipment. Its purpose is to monitor the prevalence of enamel defects and thus to determine the public health significance of enamel defects (1).

SCOTS is an abbreviation that means (2):

S - Scotland. It was initially adopted by the Scottish Health Boards and used in epidemiological studies in Scotland.

C - Child. Implies evaluation of children from any community in order to determine the presence of DDE.

O - Opacity. Description of opacity or hypoplasia according to the screening criteria of the modified DDE index version.

T - Third. Records the extent of the lesion, the tooth surface being previously divided into three zones (thirds).

S - Symmetry. Records lesions symmetry.

For the examination, assessment was made of developmental defects of the upper four incisor teeth, examined wet and without prior cleaning and anomalies smaller than 1mm were excluded (3).

The aim of this study was to determine the epidemiological features of enamel defects in permanent dentition in an Iasi town school community (Romania), a prevalence study of enamel defects, and their correlation with the socio-economic status of families and type of nutrition at birth.

MATERIAL AND METHODS

The study series included 240 children aged 7-10 years attending an Iasi town secondary school, in which the SCOTS (tab. I), as a public health index of development defects of enamel, was applied to the 4 upper incisors.

TABLE I

Defect type and corresponding code in SCOTS index (1)

Description	*Codes*
A. Type of lesion	
Normal	0
Demarcated opacities: white-cream or yellow-brown	1
Diffuse opacities	2
Hypoplasia	3
Demarcated and diffuse opacities (codes 1&2)	4
Demarcated and hypoplastic opacities(codes 1&3)	5
Diffuse and hypoplastic opacities(codes 2&3)	6
Others (defects which cannot be classified under codes 1-6, for ex.: discromia)	7
All demarcated, diffuse and hypoplastic opacities(codes 1&2&3)	8
Cannot be examined (ex.: missed or with brackets)	9
B. Surface extent of the lesion	
Less than one third of the tooth, from the incisal edge, affected	1
Between one and two-thirds of the tooth, from the incisal edge, affected	2
More than two-thirds of the tooth, from the incisal edge, affected	3
C. Lesion symmetry	
No symmetrical defects	1
Only one type of defect, and it is symmetrical	2
More than one type of defect, all symmetrical	3

Clinical examination was performed by a single dentist in daylight without prior teeth drying or cleaning. Tooth surfaces were visually inspected and the suspect surfaces explored with the dental probe to assess the contours and surface defects (4). When there were doubts about the diagnosis, the dental surface was classified as normal (SCOTS =

0), and when the defect was obvious and could not be promptly included in one of the category of defects provided by SCOTS index, it was included in the category "other defects" (5). Data about the socio-economic status of children families and type of nutrition at birth were obtained through a questionnaire filled out by the parent at the same time with signing a consent to participate in the study. Statistical processing of the obtained data was performed using *SPSS 16.0*®

RESULTS AND DISCUSSION

The series structure shows a slightly higher frequency of boys (52.5%), sex ratio = 1.1: 1 and children aged 8 years (39.2%) (tab. II).

TABLE II

Sex and age distribution of study series

Age (years)	Female		Male		Total	
	n	%	n	%	n	%
7	14	5.8	16	6.7	30	12.5
8	42	17.5	52	21.6	94	39.2
9	40	16.7	32	13.3	72	30.0
10	18	7.5	26	10.8	44	18.3
Total	114	47.5	126	52.5	240	100.0

Following clinical examination, DDE were found in 28 children; after lesions smaller than 1 mm, and lesions located on other teeth than upper incisors were excluded, 22 of the study children (9.2%) remained in the study (tab. III).

Diffuse opacities (SCOTS = 2) were most common (54.5%), and the combination of diffuse opacity and hypoplasia (SCOTS = 6) the rarest (9.1%). Distribution of children according to SCOTS score is shown in fig. 1.

TABLE III

Children with developmental defects of permanent teeth according to SCOTS classification

Defect	Nr.of children	% of total defects	% of total series
SCOTS 1	4	18.2	1.7
SCOTS 2	12	54.5	5.0
SCOTS 3	4	18.2	1.7
SCOTS 6	2	9.1	0.8

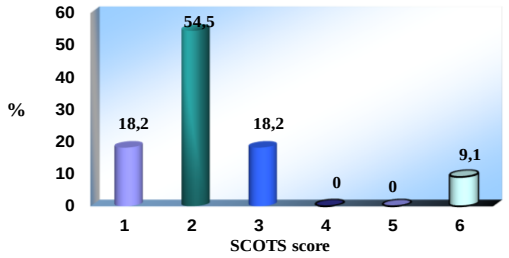

Fig. 1. Distribution of children according to SCOTS score

In the studied cases, the SCOTS score ranged between 1 and 6, with an average value of 2.32 ± 1.25. The average, minimum and maximum values of SCOTS score depending on DDE location are shown in table IV.

TABLE IV

SCOTS score values depending on the location of enamel defect

Enamel defect	Nr. of children	%	min	max	$\bar{x} \pm \sigma$
Maxilla	18	7.5	1	6	2.17 ± 1.03
Maxilla + mandible	4	1.7	2	6	3.47 ± 1.66

Average value of SCOTS score is significantly higher if the defect is found simultaneously on the maxilla and mandible than if the defect location is only maxillary (t-Student = 2.21, GL = 9, P <0.05).

In the 22 children enrolled in the study, 88 incisors were examined, and only 42 (47.7%) had various forms of developmental defects of enamel (table V). Most affected were the central incisors (30, 71.4%) and the upper left hemi jaw (26 central incisors and left lateral incisors, 61.9%).

TABLE V

Defect prevalence depending on the affected tooth

Score / Tooth	SCOTS 1	SCOTS 2	SCOTS 3	SCOTS 6	Total
1.1	2	8	-	2	12 (28.6%)
1.2	-	4	-	-	4 (9.5%)
2.1	4	8	6	-	18 (42.9%)
2.2	-	6	2	-	8 (19.0%)
Total	6 (14,3)	26 (61,9%)	8 (19,0%)	2 (4,8%)	42

Of the 42 affected teeth, 61.9% had an extension defect on more than one third of the tooth surface, and about 9.5% had an injury over two thirds of the tooth surface (fig. 2).

We noticed that 66.7% of affected teeth (n = 28) had asymmetric lesions, and that asymmetric diffuse opacities (38.1%, n = 16) were most common. Single symmetrical lesions were present on 33.3% (n = 14) of incisors. There was no record of multiple symmetrical lesions on the index teeth (tab. VI).

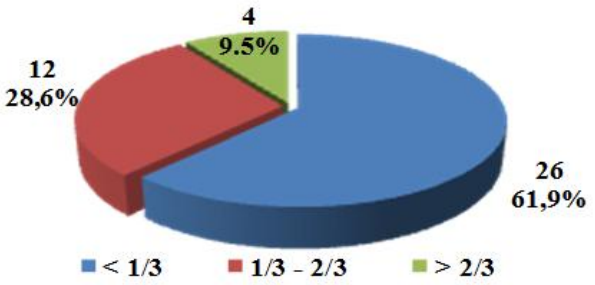

Fig. 2. Extension of surface defect

TABLE VI

Share of defect depending on the affected tooth

Defect / Symmetry	SCOTS1	SCOTS2	SCOTS3	SCOTS6	Total
Not symmetrical defects	4 (9.5%)	16 (38.1 %)	6 (14.3%)	2 (4.8%)	28 (66.7%)
Only one type of defect, and it is symmetrical	2 (4.8%)	10 (23.7%)	2 (4.8%)	-	14 (33.3%)

In the 22 children who presented defects on upper incisors no statistically significant gender and age-related differences have been identified ($p > 0.05$). Unfavorable socio-economic status proved to be a potential risk factor in the developmental defect of enamel ($p = 0.034$) (tab. VII).

In our study, there was a correlation between the prevalence of developmental defects of enamel and a potential risk factor represented by socio-economic status of children families; statistically significant differences in DDE prevalence between children from lower middle class (34.2%) and lower class families (10%) ($p < 0.001$) were found. Thus family socio-economic status was confirmed by logistic regression as a potential risk factor in DDE (fig. 3).

By correlation with the type of nutrition at birth, we noticed that artificially fed children tend to show more affected teeth and even more affected tooth surfaces (4%) than naturally fed children (2%), but the difference is not statistically significant ($p > 0.05$) (fig. 4).

TABLE VII

Epidemiological features depending on SCOTS score

Parameter	SCOTS ≤ 2	SCOTS > 2	Statistical significance
Gender			
Male	10	4	$\chi^2 = 0.10$; GL = 1; p = 0.752
Female	6	2	
Age group			
7 - 8 yers	10	2	$\chi^2 = 0.55$; GL = 1; p = 0.458
9 - 10 yers	6	4	
Socio-economic status			
Lower middle class	8	6	$\chi^2 = 4.50$; GL = 1; p = 0.034
Lower class	8	0	

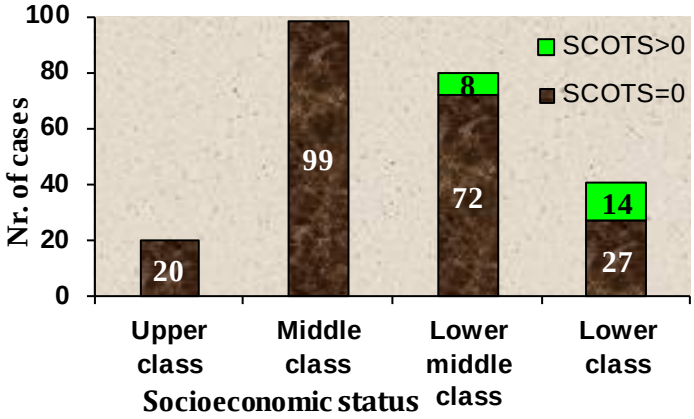

Fig. 3. Trend of DDE in children according to socio-economic status

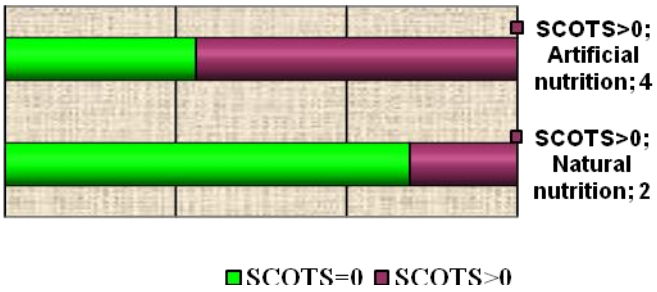

Fig. 4. Correlation between the prevalence of enamel defects and type of nutrition at birth

CONCLUSIONS

In our study in children aged 7 to 10 years the prevalence of enamel development defects assessed by SCOTS index was 9.2 percent.

SCOTS index restricts the clinical examination to the four upper incisors which makes it suitable for screening studies, but provides a lower value than the real number of defects, which requires examination of all teeth on the arch.

The highest frequency was recorded for opacities (72.7%; 54.5% diffuse opacities and 18.2% demarcated opacities), followed by hypoplasia (18.2%) and combinations of defects (9.2%).

A highly significant prevalence ($p<0.001$) of enamel development defects was noticed and correlated to socio-economic status as risk factor.

There was no statistically significant difference in the value of SCOTS scores and children gender or age

By correlation with the type of nutrition at birth, we did not observe any statistically significant differences between children fed naturally or artificially.

FUNCTIONAL ANATOMY OF THE TEMPOROMANDIBULAR JOINT (I)

Anca Sava[1], Mihaela Monica Scutariu[2]
University of Medicine and Pharmacy „Grigore T. Popa" - Iasi
School of Dental Medicine
1. Discipline of Anatomy and Embryology
2. Discipline of Oral Diagnosis

FUNCTIONAL ANATOMY OF THE TEMPOROMANDIBULAR JOINT (I). (Abstract): Jaw movement is analyzed as the action between two rigid components jointed together in a particular way, the movable mandible against the stabilized cranium. Jaw articulation distinguishes form most other synovial joints of the body by the coincidence of certain characteristic features. Its articular surfaces are not covered by hyaline cartilage as elsewhere. The two jointed components carry teeth the shape, position and occlusion of which having a unique influence on specific positions and movements within the joint. A fibrocartilaginous disc is interposed between upper and lower articular surfaces; this disc compensates for the incongruities in opposing parts and allows sliding, pivoting, and rotating movements between the bony components. These are the reasons for our review of the functional anatomy of the temporomandibular joint. **Key words**: TEMPOROMANDIBULAR JOINT, JAW MUSCLES, MANDIBLE POSTURES AND MOVEMENTS

The craniomandibular articulation is a peculiar, bilateral, roving fulcrum around which moments of force turn into a complex jaw-lever system.

Each joint involves the articular fossa above and the mandibular condyle below (1). The articular eminence, a transversly elliptical region sinuously curved in the sagittal plane and tilted forward at 25° to the occlusal plane, forms most of the articular surface of the articular fossa. Its steepness is variable and becomes flatter in the edentulous. Its anterior limit is the summit of the articular eminence, a transverse ridge that extends laterally out to the zygomatic arch as far as the articular tubercle. Articular tissue extends anteriorly beyond the articular summit and on to the preglenoid plane. Posteriorly it extends behind the depth of the fossa as far as the squamotympanic fissure. A postglenoid tubercle (at the root of the zygomatic arch, just anterior to the fissure) is usually poorly developed in human skulls (2).

The articular surface of the mandibular condyle is slightly curved and tilted forward at about 25° to the occlusal plane. In coronal plane its shape varies from that of a gable to roughly horizontal in the edentulous.

Fibrous capsule

The lower part of the joint is surrounded by tight fibers which attach the condyle of the mandible to the disc. The upper part of the joint is surrounded by loose fibers which attach the disc to the temporal bone. Thus, the articular disc is attached separately to

the temporal bone and to the mandibular condyle forming what could be considered two joint capsules. Longer fibers joining the condyle directly to the temporal bone may be regarded as reinforcement.

Ligaments

Sphenomandibular ligament is medial to, and normally separate from the capsule. It is a flat, thin band that descends from the spine of the sphenoid and widens as it reaches the lingual of the mandibular foramen. With the jaw closed, there is about 5 mm slack within the ligament, but it becomes taut when the jaw is about half open. Lateral pterygoid and auriculotemporal nerve are lateral relations: chorda tympani nerve lies near its upper end and medial pterygoid is an infero-medial relation.

Stylomandibular ligament is a thickened band of deep cervical fascia that stretches from the apex and adjacent anterior aspect of the styloid process to the angle and posterior border of the mandible. Its position and orientation indicate that it cannot mechanically constrain any normal movements of the mandible and does not seem to warrant the status of a ligament of the joint.

Temporomandibular (lateral) ligament is attached above to the articular tubercle on the root of the zygomatic process of the temporal bone. It extends downwards and backwards at an angle of 25° to the horizontal, to attach to the lateral surface and posterior border of the neck of the condyle, deep to the parotid gland. It appears to be poorly developed in the edentulous.

Synovial membrane lines the inside of the capsule of the joint but does not extend to cover the disc or the articular surfaces.

Articular disc

The transversal oval articular disc is composed predominantly of dense fibrous connective tissue (3). It has a thick margin which forms a peripheral annulus and a central depression in is lower surface that accommodates the articular surface of the mandibular condyle. The depression probably develops as a mechanical response to pressure from the condyle as it rotates inside the annulus.

The functions of the articular disc remain controversial. It is generally believed that the disc helps to stabilize the temporomandibular joint. The articulating surfaces of the mandibular condyle and the articular fossa fit together poorly and are therefore separated by an irregular space. Muscle forces control the position of the mandible, and therefore of the condyle, in relation to the articular eminence, and these in turn set the shape and thickness of the irregular space (4).

Posturess

The term posture is preferable, since it emphasizes the disposition of the parts of the body with reference to each other, which is precisely the feature to be analyzed. The most commonly discussed of these postures are usually labeled rest position and hinge position, along with centric and other occlusal position (5). Unfortunately, the terminology of some of these positions is confusing and controversial in the current literature. Here only the simplest and least equivocal terms will be used.

Resting posture (rest position). The resting posture of the mandible is the position the lower jaw assumes when the mandibular muscles are at „rest", provided that the individual stands or sits at ease in the upright posture and holds the head so that the gaze is toward the horizon. This provi-

so is essential because it specifies that the entire head and neck should also be in normal rest position. If the head is flexed forward, the bunched-up soft structures between chin and chest tend to shove the mandible forward from its rest position. If the head is extensed backward, the opposite displasement occurs. Then such structures as skin, fascia, and facial muscles (for example, platysma) are stretched and pull the mandible down and back form the rest position.

Therefore it must be clearly understood that the term „resting posture" does not imply a fixed or static position (6). The position varies continuously depending on numerous factors, including momentary bodily postures, immediately preceding activities, fatigue, and perhaps even the time of the day. That any such position is precisely reproductible with any degree of confidence is wholly an illusion.

In the resting posture the teeth are clearly not in contact. The space between upper and lower teeth is called the free-way space, or interocclusal clearance. This normally measures from 2 to 5 mm between incisors. In this position the lips touch lightly. Thus, it is also clear that rest position is entirely independent of the number, form, position, or even the presence or absence of teeth. Instead, rest position is entirely dependent on the resting tonus of the mandibular musculature and gravity. No muscle is ever totally atonal (except perhaps under the influence of certain drugs, deep anesthesia, or unconsciousness). The residual tension of a muscle „at rest" is termed resting tonus, but this too must be defined with care.

Resting tonus is due both to the innate turgor and elasticity of muscular and fibrous tissue and to the discontinuous contractions of muscle bundles in response to an alert nervous system. But in addition, in antigravity muscles, such as those of the jaw, intermittent reflex contraction of a number of muscle fibers is always present (5). Thus, as some fibers become fatigued, others take up the tension so that a given percentage of the fibers maintains, at all time, firm contact between articulating joint surfaces and thus ensures the integrity of the articulation. This mechanism becomes especially critical in all highly movable joints where the stability of the articulation cannot be greatly dependent on other features of joint structure (for example, the shoulder joint). Thus, in normal rest position of the jaw, the antero-superior articular surfaces of the mandibular condyles are pulled toward the posterior slopes of the articular eminences of the temporal bone. As shown, these surfaces are protected by articular coverings. The thinnest parts of the articular discs intervene between these surfaces, and all are held in these relations by the conditions of resting tonus mentioned above.

This is simply one instance of the general physiologic principle in which the proper relations of all body parts are maintained by muscle tone. Though considerably lower during sleep, tonus is even then not entirely lost. Obviously, as muscle tonus is constant under constant conditions, so are the rest positions of the mandible. In aberrant conditions, such as disease, exhaustion, or nervous tension, these relationships may change. Certainly, it is well understood that „constancy" in a living organism means simply that the range of variation is small but constant.

Clinically, the range of the resting posture is of great significance because it specifies the crucial limits to any „bite-

raising" prosthetic procedures. If the bite is „opened" (raised) as far as the rest position (meaning that the teeth touch in this position), the mandibular musculature is severely stressed. Constant contact of the teeth, however light, causes the neural end organs in the periodontium to signal this contact to the motor nucleus of the fifth nerve in the brainstem. This disrupts the normal, long established firing pattern. The disrupted pattern then deprives the muscle fibers of their normal resting sequences. Trauma to teeth, supporting structures, and joint structures, as well as muscle spasm and pain, are the obvious consequences.

Hinge posture of the jaw joint is one that can be located with some accuracy. It is the posture in which the condyles rest at the most retruted limit, against the thick back rims of the discs below the front of the fossa when the cusps of the teeth are just cleared of contact. It is from this position that a practically „pure" hinge raising and lowering of the jaw can be made. The simple hinge swinging of the mandible describes a small arc and is accomplished only when the mandible is forcefully retruded. The posterior most retrusion that the condyle can reach is determined by the lenght of the tensed inner horizental band of the craniomandibular ligament. Since the lenght of this band is constant, the clinical registration of this position can be repeated accurately. The hinge movement rotates around a common horizontal axis, which runs approximately through the centers of both condyles. Because of the appreciable asymmetries between both sides of the skull, it is highly unlikely that the axis will ever run exactely through a juncture of horizontal and frontal planes. The location of this position is said to be useful in some clinical procedures. One features of this is obviously significant; it specifies that the normal rest position of the condyle must be some short distance anterior to the hinge position.

Centric occlusal posture signifies some sort of contact between upper and lower teeth. Centric occlusion denotes a concept of normal mandibular posture in which the dentition is occluded with all teeth fully interdigitated at the same time that all other kinetic components of the oral apparatus are in „harmonious balance". The condyles are slightly rotated backward and are at or slightly retruded from the level of their position at rest. Ideally, that is the position the jaw should reach if snapped shut from the open position when the head and neck are in the upright posture. This is the most likely to occur in healthy young adults with a full complement of teeth and what is classically considered a normal occlusion. It has been shown that, in the overwhelming majority of cases, the mandible can be retruded from this position some 0.5 to 1 mm, if the teeth are barely freed. As noted above, it is obvious that the normal centric occlusal posture must be slightly forward of the position that the masticatory musculature can actually achieve. Thus, the ability to move the mandible slightly backward from the centric occlusal relation is at least one distinct sign of a well-balanced oral apparatus. The hinge position is an extreme position, and it is entirely contrary to well-known principles of biologic constructs that any normal joint be habitually postured in such a strained position.

Protrusive occlusal relation is the po-

sition of occlusion in which the incisal edges of the four lower incisors contact the incisal edges of the upper centrals and sometimes the laterals. Normally, all the other teeth are not in occlusion. The condyles are slightly forwardly rotated and moved downward and forward to a level at or near the peak of the articular eminence.

Lateral occlusal relation is the position when the upper and lower posteriors of the ipsilateral side contact along the line of the crests of the buccal and lingual cusps. In unworn teeth the cusps bulge in curves so that the contacts are at spots where opposing contours meet. In worn teeth the contours are flattened, and contact lines may be almost continuous. In the natural dentition, the teeth of the controlateral side are not in occlusion.

EFFECT OF SOME BIOTIC ELICITORS ON FLAVONOIDS PRODUCTION IN *DIGITALIS LANATA* CELL CULTURES (Abstract): A method to improve the secondary metabolites production in plant cell cultures is the use of elicitors (biotic or abiotic). In this paper we investigated the effect of two biotic elicitors, *Botrytis* and *Sclerotinia,* on the flavonoids production, an important category of secondary metabolites, in *Digitalis lanata* suspension cultures. **Material and method**: Were used two cell lines: line 11 and line 13C 100 (aged 10 days). Were used two concentrations of elicitors (1 ml and 2 ml/100 ml suspension, respectively). Flavones were determined by a spectrophotometric method, according to Romanian Pharmacopoeia no. X (*Cynarae Folium* monography). **Results**: For both cell lines and for both elicitors, flavonoids accumulation grew with elicitation time and elicitor concentration. The highest flavonoids production took place after 96 hours elicitation time for the highest elicitor concentration (2ml/100ml suspension). So, line 11 accumulated 1000 mg% flavonoids with *Botrytis* and 999.81 mg% with *Sclerotinia*. Line 13C 100 accumulated 1051,65 mg% flavonoids with *Botrytis* and 1025,43 mg% with *Sclerotinia*. For all experiments, *Botrytis* (both concentration) induced a higher flavonoids accumulation for line 11 than *Sclerotinia*. Line 13C 100 responses to elicitor action is stronger for *Sclerotinia* for higher elicitor concentration than for same concentration of *Botrytis*. **Key words**: BIOTIC ELICITORS, *BOTRYTIS, SCLEROTINIA,* FLAVONOIDS

Elicitorii reprezintă, în general, compuşi de origine biologică implicaţi în interacţiunea plantă-agent patogen. În contextul acumulării de metaboliţi în culturi celulare vegetale, elicitorii sunt mediatori ai stresului microbian (elicitori biotici) sau sunt agenţi de stres cum ar fi: lumina UV, presiunea osmotică sau ioni ai metalelor grele (elicitori abiotici) (1).

Răspunsul dat de culturile vegetale *in vitro* la expunerea la elicitori a fost studiat prima dată pentru a aprofunda cunoştinţele despre chimia şi biochimia produşilor de elicitare, fitoalexinele, compuşi antimicrobieni sintetizaţi de plantă, componenţi ai sistemului de apărare al plantei (2). S-a descoperit astfel că elicitarea este un proces inductiv care are ca rezultat creşterea nivelelor ARN-m pentru diferite enzime (calcon sintetaza, calcon izomeraza), fiind primul

răspuns într-o serie de procese biochimice ulterioare. Consecutiv creşterii activităţii enzimatice se produce sinteza fitoalexinelor (3).

În cazul elicitorilor biotici, experimentele se realizează folosind culturi complexe de omogenate de origine bacteriană sau fungică sau cu fracţiuni ale acestor omogenate. Au fost folosiţi agenţi patogeni (*Phytophthora, Botrytis, Verticillium*), precum şi material nepatogen (*Aspergillus, Micromucor, Rhodotorula*) sau condiţionat patogen (*E.coli*) (2).

O abordare recentă cu rezultate foarte bune este folosirea unor combinaţii de elicitori biotici şi abiotici sau combinaţia elicitori biotici şi înnoirea mediului pentru obţinerea unor producţii sporite de metaboliţi secundari (4, 5).

Sinteza flavonelor, o categorie importantă de fitoalexine (6), în planta *Digitalis lanata* sau în culturi celulare de *Digitalis,* a fost puţin studiată (7). În lucrări anterioare am studiat efectul unor elicitori abiotici asupra producţiei unor metaboliţi secundari: glicozide cardiotonice (8, 9) şi flavone (sub tipar) în culturi celulare de *Digitalis lanata*. Rezultatele obţinute au fost foarte bune.

În lucrarea de faţă am studiat efectul elicitării culturilor de suspensii celulare de *Digitalis lanata* cu preparate obţinute din ciupercile patogene *Botrytis cinerea* şi *Sclerotinia tulipifera* asupra acumulării de flavone.

MATERIAL ŞI METODE

Materialul vegetal: Au fost luate în studiu două linii celulare de *Digitalis lanata*: linia 11 şi linia 13C 100 obţinute anterior (10). Suspensiile celulare au fost crescute într-un mediu lichid Murashige-Skoog (MS) (11) suplimentat cu 1 mg/l acid 2,4-diclorfenoxiacetic şi 2 mg/l 6-benziladenină, în vase Erlenmeyer de 300 ml ce conţineau 50 ml mediu nutritiv. Ele au fost subcultivate la un interval de 14 zile, raportul dintre inocul şi mediul proaspăt fiind de 1:6. Vasele de cultură au fost menţinute pe un agitator rotativ orizontal (100 rpm) la o fotoperioadă de 16 ore şi la o temperatură de 25°C.

Preparatele (omogenatele) fungice: pentru obţinerea lor ciupercile *Botrytis* şi *Sclerotinia* au fost izolate de pe diferite organe infestate ale plantelor şi cultivate pe un mediu Williams şi Ellis (12) în cutii Petri. După dezvoltarea miceliului pe suprafaţa mediului, o porţiune de circa 1 cm^2 a fost detaşată şi inoculată în 100 ml mediu lichid MS, fără fitohormoni. Vasele au fost agitate pe agitatorul rotativ la semiîntuneric timp de 6 zile. Miceliile dezvoltate, împreună cu mediul, au fost omogenizate cu un omogenizator de tip Polytron şi autoclavate. Omogenatele obţinute au fost inoculate în vasele conţinând suspensiile celulare de *Digitalis lanata* aflate în ziua a 10-a de cultură în concentraţii de 1 ml (concentraţia I) şi respectiv, 2 ml/100 ml suspensie (concentraţia II). Recoltarea probelor s-a făcut după 10, 24, 48, 72 şi respectiv, 96 de ore.

Analiza cantitativă a flavonelor s-a efectuat spectrofotometric conform FR X (monografia *Cynarae folium*) folosind $AlCl_3$ ca reactiv şi o curba-etalon de rutozidă (13). Concentraţia flavonelor a fost exprimată în mg/100g s.u. (mg%).

REZULTATE

Rezultatele obţinute sunt prezentate în tabelele I, II şi în figurile 1, 2, 3, 4.

DISCUŢII

Pentru testarea efectului elicitării biotice asupra culturilor celulare de *Digitalis lanata* s-au luat în calcul mai multe criterii şi anume: vârsta culturii, durata elicitării şi concentraţia elicitorului (14). Aceşti parametri au fost stabiliţi pe baza experimentelor anterioare efectuate de noi (vârsta culturii, durata elicitării) (8, 9) şi a datelor existente în literatura de specialitate (concentraţia elicitorului) (15, 16).

Modificările ce s-au produs în urma elicitării au depins de durata de contact dintre elicitor şi suspensia celulară, de tipul şi concentraţia elicitorului şi de linia celulară folosită.

Pentru ambele linii celulare, cantitatea de flavone acumulată a crescut direct proporţional cu timpul de elicitare şi cu concentraţia elicitorului. Aceste date sunt în concordanţă cu datele din literatura de specialitate (17). Acumularea cea mai mare de flavone se produce după 96 de ore de tratament, pentru concentraţia II a elicitorului, atât pentru linia 11, cât şi pentru linia 13C 100. Astfel, linia 11 sintetizează 1000 mg% flavone folosind *Botrytis* concentraţia II şi 999,8 mg% flavone folosind *Sclerotinia* concentraţia II (tab.I, fig. 2, 4). Linia 13C 100 acumulează 1051,65 mg% flavone folosind *Botrytis* concentraţia II şi 1025,43 mg% flavone folosind

Sclerotinia concentraţia II (tab. II, fig. 2, 4).

Aceste rezultate sunt în concordanţă cu cele obţinute în culturi de *Brugmansia candida*, elicitate cu diferite omogenate fungice, unde producţia de scopolamină a crescut de 7 ori folosind concentraţia cea mai mare de elicitor, după timpul maxim de elicitare (7 zile) (18). De asemenea, în culturi de *Ononis arvensis* elicitate cu *Aspergillus terreus*, cantitatea cea mai mare de flavone se acumulează după 7 zile de la adăugarea elicitorului, respectiv perioada maximă de elicitare (19). În schimb, în culturi de *Bellis perenis* elicitate cu omogenate de *Candida utilis*, producţia cea mai mare de flavone a fost obţinută după 48 de ore de elicitare, folosind concentraţia cea mai mare de elicitor (20), iar în culturi de *Catharanthus roseus*, elicitate cu omogenate de *Aspergillus niger*, cantitatea cea mai mare de ajmalicină s-a acumulat după 48 de ore de tratament (14). Similar, în culturi de *Ononis arvensis* elicitate cu *Escherichia coli*, producţia de flavone a fost maximă după 48 de ore de la adăugarea elicitorului (19).

Comparând cele două linii celulare luate în studiu, se observă că linia 13C 100 este mai sensibilă la acţiunea elicitorilor şi sintetizează cantităţi mai mari de flavone, pentru ambele tipuri şi concentraţii de elicitori, precum şi pentru toţi timpii de elicitare (tab. I, II).

În acest experiment tipul elicitorului nu influenţează semnificativ producţia de flavone, cele două linii celulare răspund aproximativ egal la acţiunea celor două tipuri de omogenate fungice, cu un uşor avantaj pentru *Sclerotinia* (tabele I, II şi figurile 3, 4).

Analizând rezultatele, merită subliniat faptul că elicitorul *Botrytis* la concentraţia I stimulează cel mai puternic producţia de flavone la ambele linii celulare. Astfel, pentru linia 11, după 10 ore de tratament, cantitatea de flavone este de 474,57 mg%, iar după 96 de ore ea creşte la 871,79 mg%, mai mare cu 83%. Linia 13C 100 are o comportare asemănătoare. După 10 ore de elicitare producţia de flavone este de 568 mg%, iar după 96 de ore aceasta creşte la 976,99 mg%, mai mare cu 71% (fig. 1). Rezultate asemănătoare au fost obţinute în culturi de *Ononis arvensis*, elicitate cu *Pseudomonas aeruginosa*, unde se observă o stimulare a producţiei de flavone cu 83% folosind concentraţia cea mai mică de elicitor, după 7 zile de tratament (19).

După evaluarea tuturor rezultatelor obţinute se observă că producţia maximă de flavone, 1051,65 mg%, a fost indusă de elicitorul *Botrytis*, concentraţia II, timp de elicitare 96 de ore, linia celulară 13C 100 (tab. I, fig. 2).

CONCLUZII

Cercetările noastre au evidenţiat că elicitorii biotici utilizaţi în acest experiment, la fel ca şi cei utilizaţi în experimentele anterioare, stimulează puternic producţia de flavone, în culturi celulare de *Digitalis lanata*, la nivel de laborator. Aceste rezultate ne demonstrează că experimentele pot continua cu transpunerea lor la scară de bioreactor.

SUSCEPTIBILITY TESTING OF *STREPTOCOCCUS PNEUMONIAE* AND VIRIDANS STREPTOCOCCAL ISOLATES AGAINST: QUINOLONES, OXAZOLIDINONES AND GLYCOPEPTIDES (Abstract): The **aim** of this study was to test the susceptibility of 100 strains (pneumococci and viridans streptococci) isolated from oral and respiratory tract infections and their complications, against one antibiotic of each of the following classes: quinolones, oxazolidinones and glycopeptides. **Material and methods:** The Etest has been used in order to investigate the susceptibility of the isolates against levofloxacin, linezolid and vancomycin. **Results and Conclusions**: As expected, the results of the study indicated that all isolates were susceptible to linezolid and vancomycin. In contrast to the pneumococcal isolates, which were all susceptible to levofloxacin, 10% of the viridans strains showed resistance to this quinolone. When fluoroquinolones are needed as an alternative to the beta-lactam antibiotics in infections in which oral streptococci are involved, the *in vitro* susceptibility testing is required. **Key words:** STREPTOCOCCUS PNEUMONIAE, ORAL STREPTOCOCCI ANTI-MICROBIAL SUSCEPTIBILITY.

The first place in the aetiology of the bacterial respiratory infections is conferred to the pneumococci. Based on molecular studies, *Streptococcus pneumoniae* should be considered one of the species of *S. mitis* group, which belongs to the oral streptococci, but due to its special role in human pathology is treated separately (1, 2, 3, 4). The oral streptococci are represented by the streptococci that normally inhabit the oral cavity. The term "viridans streptococci" is also commonly used for these bacteria, but never for *S. pneumoniae*. Even if oral streptococci belong to the normal body flora (predominantly to the flora of the mouth and upper respiratory tract), they are sometimes involved in infections, as unique microbial agents or mostly, in association with other microorganisms (5). Several recent studies have brought scientific evidence also regarding the role of these streptococci as pathogens in respiratory infections (6). Numerous authors have evidenced the emergence of antibiotic resistance in both Streptococcus pneumoniae and viridans streptococci. Moreover, it is well-known the possibility of gene transfer from viridans streptococci to pneumococci (7).

MATERIAL AND METHODS

Fifty pneumococcal and 50 oral streptococcal strains stored on cryobiles (AES Laboratoire, France) at -70^{0}C, at the laboratory of the Microbiology Chair, Faculty of Dentistry, University of Medicine and Pharmacy "Carol Davila", Bucharest, have been tested for their susceptibility to: levofloxacin, linezolid and vancomycin. These isolates originated from paediatric patients among those diagnosed during 2010 with different oral and respiratory tract infections at the following hospitals in Bucharest: the Clinical Hospital of Infectious and Tropical Diseases "Dr. Victor Babeş", the Emergency Clinical Hospital for Children "Grigore Alexandrescu", the Ear-Nose-Throat Department - "Sfanta Maria" Hospital and "Prof. Dr. Dan Theodorescu" Hospital.

The speciation of the 50 isolates of viridans streptococci by the Rapid ID 32 STREP system (BioMérieux, France) indicated that the strains belonged to the following species: *S. anginosus*, *S. mitis*, *S. oralis*, *S. sanguinis* and *S. parasanguinis* (previously communicated data).

The investigation of the susceptibility of the 100 isolates to the 3 antibiotics mentioned above was done using the Etest (BioMérieux, France/AB Biodisk, Sweden). The reference strain *S. pneumoniae* ATCC 49619 was used as quality control. The bacterial inoculum was prepared in Müller-Hinton broth (Sanimed, Romania) and standardized at 0.5 McFarland turbidity (or 1 McFarland for mucoid strains), growth on Müller-Hinton agar supplemented with 5% sheep blood (Sanimed, Romania). The Petri plates were incubated in 5% CO_2 atmosphere at 37^{0}C for 24h. The interpretation of the minimum inhibitory concentration (MIC) values has been done according to the Clinical Laboratory Standards Institute (CLSI) recommendation (8).

RESULTS

The MIC values ranged between: 0.094 – >32 μg/ml for levofloxacin, 0.125 – 0.75 μg/ml for linezolid and 0.125 – 1 μg/ml for vancomycin (Table I). The 50 isolates of *S. pneumoniae* were sensitive to the tested antimicrobial agents. All the viridans streptococcal strains were susceptible to linezolid and vancomycin, but only 45 of them were sensitive to levofloxacin (Fig.1.). The 5 isolates of *S. oralis* which were resistant to the respective fluoroquinolone showed high values of MIC (≥32 μg/ml).

TABLE I

The minimum inhibitory concentration (MIC) values of the antibiotics tested against the pneumococcal and viridans streptococcal isolates

BACTERIA (no. of isolates)	ANTIBIOTIC	VALUES OF MIC (μg/ml)			
		MIC_{min}*	MIC_{max}**	MIC_{50}***	MIC_{90}****
S. pneumoniae **(n = 50)**	Levofloxacin	0.19	1.5	0.38	0.50
	Linezolid	0.125	0.75	0.38	0.75
	Vancomycin	0.125	1	0.50	0.75
Viridans streptococci (n = 50)	Levofloxacin	0.094	>32	0.5	1.5
	Linezolid	0.19	0.75	0.38	0.50
	Vancomycin	0.38	1	0.75	1

DISCUSSION

It has been already noticed that resistance of pneumococci to beta-lactam antibiotics, macrolides and trimethoprim-sulfamethoxazole in pediatric patients with respiratory tract infections is increasing on an annual basis (9). There are some articles reporting isolates of *S. pneumoniae* resistant to quinolones too. For example, Karlowsky et al. found a percentage of resistance to levofloxacin of 0.1% among the pneumococcal strains isolated from pediatric patients in the 2000-2001 and 2001-2002 respiratory illness season surveillance studies in the United States (8). These authors stated that monitoring of fluoroquinolones susceptibility will be increasingly important in future surveillance studies, if these antibiotics become a treatment option for pediatric patients.

Another research team, from South Africa, presented data which referred to 12 cases of invasive pneumococcal disease, with 5 deaths, due to levofloxacin non-susceptible strains in pediatric patients under 15 years old, and a high prevalence of nasopharyngeal carriage (of 89%) of *S. pneumoniae* strains non-susceptible to this fluoroquinolone, also in children aged under 15 years. The results of their study suggested that the treatment with fluoroquinolones of multidrug-resistant tuberculosis in pediatric patients has led to the emergence of invasive pneumococcal infection caused by levofloxacin non-susceptible strains and to its nosocomial spread (10).

In the present study, none of the pneumococcal isolates were resistant to levofloxacin. In contrast to *S. pneumoniae*, among the isolates belonging to oral streptococci there have been found some strains exhibiting a high resistance level to levofloxacin (MIC of $\geq$32 μg/ml). These fluoroquinolone resistant strains had been identified as *S. oralis*. Resistance to levofloxacin in case of viridans streptococcal clinical isolates has been reported in other articles too (11, 12). In a retrospec-

tive study referring to a period of over 30 years, Prabhu et al. observed that the percentage of viridans streptococcal strains resistant to levofloxacin isolated from patients with infective endocarditis was 0 in the period: 1971-1986, and raised to 9 in the period: 1994-2002 (13). Another research team noticed that levofloxacin prophylaxis in patients receiving chemotherapy for hematological malignancies produced an increasing resistance among the viridans streptococci during prolonged administration (14).

Even if fluoroquinolones are reasonably safe in pediatric patients, due to their specific adverse reactions, they are used in infections treatment in children only when no other effective and safe alternative exists (15).

CONCLUSIONS

As expected, linezolid and vancomycin were fully active on both pneumococcal and viridans streptococcal isolates. The percentage of levofloxacin resistance found in the viridans streptococcal isolates indicates the necessity of the *in vitro* susceptibility testing whenever the fluoroquinolones are required as an alternative to the beta-lactam antibiotics for the treatment of infections in which oral streptococci are involved. Further investigation regarding the detection of quinolone resistance mechanism is recommended too.

NOUTĂȚI

TEHNICA IMUNOCROMATOGRAFICĂ – METODĂ RAPIDĂ ŞI ACCESIBILĂ DE IDENTIFICARE A COMPLEXULUI *MYCOBACTERIUM TUBERCULOSIS*

Detecția rapidă a noilor cazuri de tuberculoză depinde de rapiditatea identificării bacteriologice. OMS a aprobat obținerea culturii micobacteriene prin însămânțarea produsului patologic în mediu lichid pentru a îmbunătăți sensibilitatea diagnosticului. Cu toate acestea, identificarea rapidă şi precisă a *Mycobacterium tuberculosis* în culturi pozitive este esențială pentru diagnostic şi tratament, în special când cultura în mediu lichid izolează micobacterii nontuberculoase (NTM). Identificarea este dificilă deoarece: metodele biochimice convenționale de identificare sunt lente, necesitând subcultura pe mediile solide, iar metodele de amplificare a acizilor nucleici depăşesc capacitatea financiară a laboratoarelor mai ales în țările cu resurse limitate. Testele de identificare rapidă imunocromatografică (TIC) de tipul truselor comerciale MPT64 au fost dezvoltate pentru a detecta complexului *Mycobacterium tuberculosis* (MTBC) în cultură pe mediu lichid. Ele sunt mai ieftine şi mai simplu de utilizat şi, astfel, pot reprezenta o alternativă în aceste cazuri. Brent et all. au comparat performanțele MPT64 TIC cu cele ale truselor de identificare genotipică de tip line probe assay (LPA) pentru identificarea MTBC în cultură pe mediu lichid în sistem BACTEC MGIT. Sensibilitatea, specificitatea, valoarea predictivă pozitivă şi valoarea predictivă negativă au fost: 97,6% (95% CI, 91.8 - 99.7), 100% (97.1 - 100), 100% (95,7 la 100) şi respectiv 98,4% (94.4 - 99.8). Nu a existat nici o diferență semnificativă statistic între LPA şi MPT64 TIC în precizia diagnosticului (P = 0.500). Aceste rezultate recomandă utilizarea TIC pentru identificarea precisă a MTBC în vederea stabilirii rapide a diagnosticului şi respectiv a tratamentului tuberculozei. CLINICAL EPIDEMIOLOGICAL STUDY OF ACUTE GASTRO-ENTERITIS OUTBREAK RECORDED IN A CHILDREN COMMUNITY, IN IASI, DURING MAY, 2009 (Abstract): Acute diarrheal disease affect all demographic structures and it is considered a major cause of morbidity and mortality for young age groups; underreporting is due to clinical and epidemiological diversity, everywhere, including the developed countries. **Material and methods.** The authors present an epidemic outbreak of acute gastroenteritis by rotavirus in a community of 240 children. Processing and interpretation of collected data was done by statistical, mathematical and computerized methods. **Results. A number of** 17 cases of acute gastroenteritis caused by rotaviruses were detected and confirmed, mostly in children older than 5 years (92%), with a tendency to focus on large group "A ", 40% . All cases showed mild forms evolving medium. **Conclusions.** The 17 cases of infection with rotaviruses were the second episode of acute gastroenteritis with the same etiology, reported over two months. Extensivity of the epidemic outbreak was moderate, with the predominant age group affected over six years (58%). Developing and implementing preventive measures included daily cleaning and decontamination standards. **Key words**: EPIDEMIOLOGY, ACUTE GASTROENTERITIS, ROTAVIRUS, CHILDREN COMMUNITY.

Boala diareică acută (BDA) este o maladie care poate afecta toate structurile demografice, cu o evoluţie clinică şi epidemiologică polimorfă, implicată în creşterea semnificativă a solicitărilor pentru asistenţa primară şi a absenteismului şcolar şi ocupaţional (1, 2, 3). Atât în România, cât şi la nivel mondial, BDA este considerată o cauză majoră de morbiditate şi de mortalitate pentru grupurile mici de vârstă, iar diversitatea manifestărilor clinice şi epidemiologice determină subraportarea, inclusiv în ţările dezvoltate (4, 5, 6, 7). Datele clinico-epidemiologice, provenind din cele mai variate arii geografice, atestă că BDA este o afecţiune cu evoluţie autolimitantă, la cei mai mulţi dintre bolnavi, cu reale posibilităţi de diagnostic, terapie şi prevenţie.

Infecţiile determinate de rotavirusuri (Rv), cu o incidenţă de peste 50%, domină etiologia gastroenteritelor acute înregistrate la copiii cu vârsta de până la 5 ani (8, 9, 10).

MATERIAL ŞI METODE

Studiul a inclus un lot de 240 copii de la grădiniţa cu program prelungit nr. 16 din Iaşi, în care a evoluat, în luna mai, 2009, un episod epidemic de infecţie cu rotavirusuri, similar cu cel din luna martie a aceluiaşi an, confirmat epidemiologic, clinic şi cu laboratorul. Informaţiile au fost obţinute de la Direcţia de Sănătate Publică Iaşi – Compartimentul de Epidemiologie a Bolilor Transmisibile şi urmare a evaluării rezultatelor obţinute în laboratorul Spitalului Clinic de Boli Infecţioase „Sf. Parascheva" Iaşi, unde s-au investigat probele biologice recoltate de la subiecţii din focarul epidemic de gastroenterită acută. Prelucrarea şi interpretarea informaţiilor acumulate au fost realizate cu ajutorul metodelor statistico-matematice clasice şi computerizate (MS Excel, EPI/INFO).

REZULTATE

1. Date epidemiologice. În intervalul 11-15 mai 2009, au fost depistate şi confirmate epidemiologic, clinic şi cu laboratorul, 17 cazuri de gastroenterită acută cauzată de rotavirusuri. Episodul epidemic a debutat brusc, cu 4 cazuri din grupuri de vârstă diferite. Numărul dominant (modal) de cazuri s-a înregistrat în zilele I, III şi IV, cu un număr de patru îmbolnăviri iar în ziua a IV-a, trei dintre copii aparţineau aceleiaşi grupe de preşcolari (fig. 1).

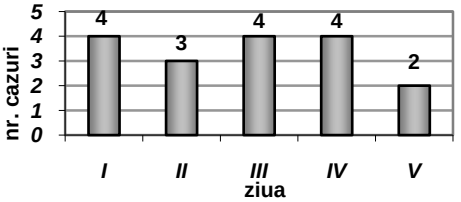

Fig. 1. Distribuţia cazurilor de gastroenterită acută cauzată de rotavirusuri, în relaţie cu data debutului clinic

Distribuţia cazurilor în relaţie cu grupurile de vârstă afectate, a arătat predominanţa îmbolnăvirilor la copiii cu vârsta de peste 5 ani (92%) (fig. 2).

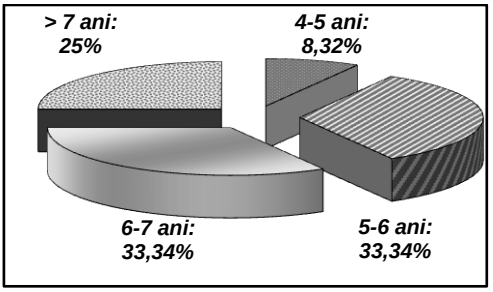

Fig. 2. Distribuţia cazurilor de gastroenterită acută cauzată de rotavirusuri în raport de grupul de vârstă afectat

Îmbolnăvirile au interesat cazuri din şase grupe de preşcolari din cele şapte existente, fiind distribuite în relaţie cu grupa din care provin, în valori de incidenţă relativ apropiate, dar cu tendinţă de concentrare la grupa mare „A" (40% dintre bolnavi), cu afectarea în special a sexului masculin (58,3%) (fig. 3).

2. Date clinice. Toţi copiii au prezentat simptomatologia caracteristică bolii, constând în scaune diareice, vărsături şi dureri abdominale; febra a fost semnalată la debut în 3 cazuri, iar alte semne clinice (mialgii, cefalee şi anorexie) au fost raportate la câte 1 caz. Pacienţii au prezentat o evoluţie de gravitate uşoară sau medie, iar 2 cazuri (16,7%) au necesitat spitalizare (internare de zi) (fig. 4).

3. Date de laborator. În laboratorul Spitalului Clinic de Boli Infecţioase "Sf. Parascheva" Iaşi, au fost investigate materiile fecale de la 49 de copii şi 21 adulţi reprezentând personalul de îngrijire. Probele au fost recoltate în primele 5 zile de la debut si examinate citologic, parazitologic, micologic, virusologic (pentru rotavirus, metoda

latex aglutinare) şi bacteriologic (pentru *Salmonella* şi *Shigella*). Rezultate pozitive pentru Rv au fost înregistrate numai la copii (34,7%) (fig. 5).

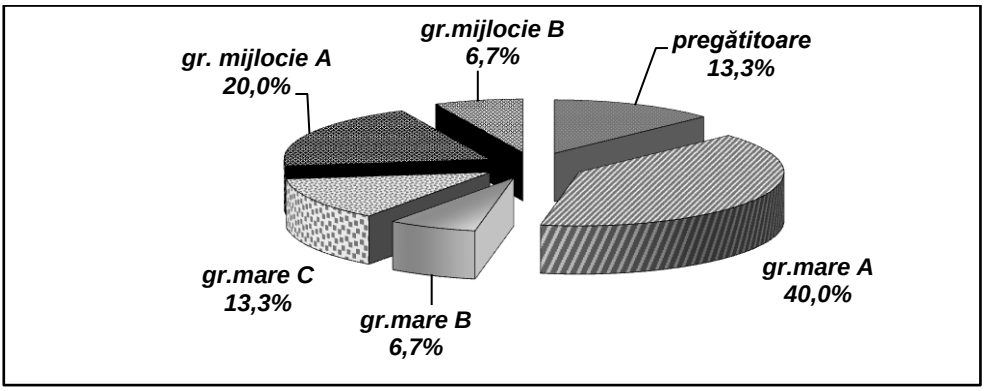

Fig. 3. Distribuţia cazurilor în raport de grupele de preşcolari

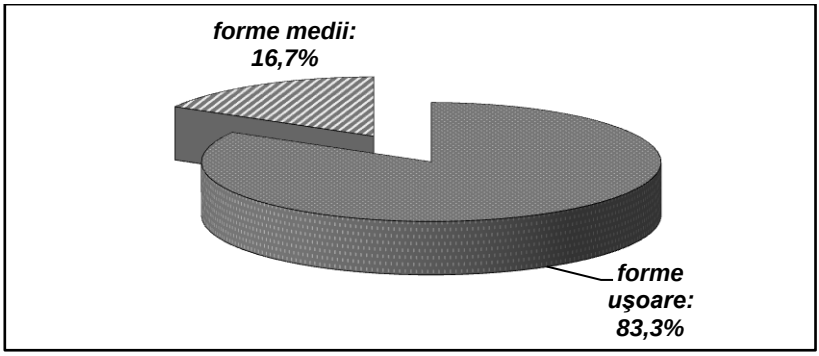

Fig. 4. Distribuţia cazurilor în relaţie cu forma clinică

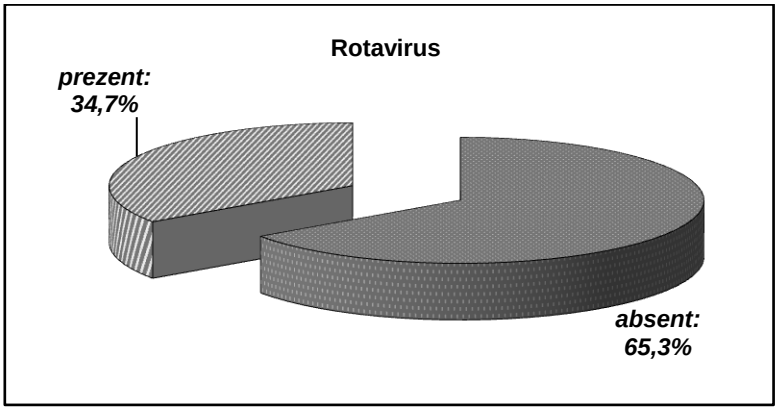

Fig. 5. Rezultatele investigaţiilor de laborator obţinute la 49 copii din grădiniţa luată în studiu

DISCUŢII

Estimări realizate în populaţia generală din SUA au indicat că ar exista, anual, aproximativ 211 milioane cazuri de BDA, iar numărul cazurilor pediatrice spitalizate a fost apreciat la 210.000 anual, din care aproximativ 10.000 decese. Din punct de vedere financiar, aceste internări au reprezentat 4% din costul tuturor internărilor, de orice cauză. La copiii sub 5 ani, în SUA, au fost raportate, anual, peste 500.000 consultaţii, cu 55.000 spitalizări şi peste 500 decese (11). În Australia, anual, 15000–20000 de copii cu vârsta sub 5 ani sunt spitalizaţi pentru gastroenterită acută gravă (12).

Un studiu de tip caz-martor, realizat în Olanda (13), având drept suport un sistem de tip „santinelă" de supraveghere a gastroenteritelor acute, a estimat impactul acestei afecţiuni la nivelul reţelei de medicină de familie, estimându-se că, anual, 128000 de persoane solicită consultaţii pentru gastroenterită acută şi că 80 persoane din 10000 prezintă un episod de gastroenterită acută. În acelaşi studiu, a fost remarcat faptul că este cel mai întâlnit agent etiologic a fost *Campylobacter* (10% din cazuri), urmat de *Giardia lamblia* (5%), *Rotavirus* (5%) Norwalk-like virus (5%) şi *Salmonella* (4%). Datele au prezentat variaţii semnificative în funcţie de teritoriul supravegheat (incidenţa mai scăzută în Nord şi în mediul rural). În Germania, potrivit primului studiu care a utilizat RT-PCR pentru precizarea etiologiei BDA la copiii spitalizaţi (14), s-a constatat că infecţiile cu rotavirus ocupă 79% din spectrul etiologic.

În unităţile de îngrijire a copiilor, dar şi în familiile în care cresc mulţi copii, s-au identificat o parte din factorii care potenţează contagiozitatea infecţiilor gastrointestinale: aglomeraţia (numărul mare de copii în îngrijire); apariţia unui caz (sau mai multe) de BDA, cu reţinerea copiilor bolnavi în colectivitate (fără izolare); acelaşi pat folosit de mai mulţi copii; suprafeţe comune pentru schimbarea scutecelor; lipsa complianţei personalului de a purta şi schimba mănuşi sau pentru spălarea mâinilor înainte şi după toaleta fiecărui copil; pardoseli acoperite cu mochetă sau covor (material textil); jucării şi alte obiecte / rechizite comune (6, 15).

CONCLUZII

Cele 17 cazuri de infecţie cu rotavirusuri înregistrate în Grădiniţa cu program prelungit nr. 16, din Municipiul Iaşi, au reprezentat un al doilea episod de gastroenterită acută cu aceeaşi etiologie, semnalat pe durata a două luni de zile. Cei mai afectaţi au fost subiecţii de sex masculin (58,3%) în vârstă de peste 5 ani (92%). Formele clinice uşoare, cu simptomatologie digestivă (scaune diareice, vărsături şi dureri abdominale) au fost înregistrate la 83,3% dintre cazuri. Probele de materii fecale au fost examinate citologic, parazitologic, micologic şi bacteriologic, inclusiv metoda latex aglutinare pentru rotavirusuri.

Extensivitatea procesului epidemiologic a avut intensitate medie, cu afectarea predominantă a grupului de vârstă peste 6 ani (58%). S-au elaborat şi aplicat măsuri de prevenţie incluzând, predominant, igienizarea cotidiană şi decontaminarea realizate cu exigenţă.

CARCINOAMELE CUTANATE ALE FEȚEI - FORME CLINICE ŞI HISTOPATOLOGICE. UN STUDIU RETROSPECTIV PE 308 CAZURI

Iulia Chiscop, Eugenia Popescu, Constantin Mihai, Cristian Budacu
Universitatea de Medicină şi Farmacie "Gr. T.Popa" Iaşi
Facultatea de Medicină Dentară
Clinica de Chirurgie Orală şi Maxilo-Facială

CUTANEOUS CARCINOMA OF THE FACE. CLINICAL AND HISTOPATHOLOGICAL FORMS. RETROSPECTIVE STUDY OF 308 CASES. (Abstract): Cutaneous carcinomas are the most frequent malignant tumors, the majority of them being located on the face, scalp and back. **Aim:** To assess the clinical presentation and pathology aspects of the patients with face skin carcinomas admitted to our clinic. **Material and methods**: The retrospective study was carried out on a series of 308 patients diagnosed and treated for cutaneous carcinoma of the face in the Department of Oral and Facial Surgery of Iasi over a period of 5 years (January 2006- December 2010). The following parameters were analyzed: demographic data, size and location of the tumor, clinical presentation, and pathology aspects. **Results**: Basal cell carcinoma accounted for 75,97% of the cases, the nodular, superficial and morphea types being the most common. As to the microscopic aspects, the nodular/solid, superficial, and basosquamous (metatypical) types were the most frequent. The squamous-cell carcinoma represented 18,18%, mainly in the ulcero-vegetant and nodular forms. The moderately and well differentiated forms prevailed. Carcinomas of the skin adnexes as well as Merkel cell carcinomas were the most rare (4,22% and 0,65%, respectively). **Conclusions:**. The face is the most common location of the cutaneous carcinomas requiring early diagnosis and treatment as a key factor to favorable long term outcome. **Key words**: CUTANEOUS CARCINOMAS, FACE, BASAL CELL, SQUAMOUS-CELL CARCINOMA

Carcinoamele cutanate se situează pe primul loc ca frecvență dintre toate tumorile maligne, fapt deloc surprinzător dacă luăm în considerare că tegumentul este cel mai întins organ al corpului uman, expus direct şi constant la agenții carcinogenetici din mediul înconjurător. Majoritatea leziunilor sunt localizate la nivelul feței, scalpului şi spatelui. Carcinoamele cutanate îşi au originea în elementele celulare ce alcătuiesc cele două straturi distincte dar interdependente ale tegumentului, epidermul şi dermul, cât şi în structurile anexe ale pielii. Se pot dezvolta pe tegumentul aparent sănătos, sau prin transformarea malignă a unor leziuni cutanate preexistente (leziuni precanceroase). Implicarea factorilor carcinogenetici externi în etiopatogenia acestora este certă, cei mai importanți fiind radiațiile solare, radiații ionizante, unele substanțe chimice şi papiloma virusul uman (1).

Pornind de la aceste date, ne-am propus identificarea celor mai frecvente forme clinice şi anatomo-patologice ale carcinoamelor cutanate ale feței. În acest scop am întreprins un studiu retrospectiv pe o peri-

oadă de 5 ani (ianuarie 2006 - decembrie 2010).

MATERIAL ŞI METODĂ

În intervalul ianuarie 2006- decembrie 2010 au fost internați și diagnosticați în Clinica Chirurgie Orală şi Maxilo-facială Iași un număr de 308 pacienți cu carcinoame cutanate ale feței. Pentru fiecare din cazurile incluse în lotul de studiu am reținut următoarele date: sex, vârstă, mediul de proveniență, localizarea tumorii, diagnosticul clinic şi cel anatomo-patologic.

Studiul clinic s-a bazat pe precizarea localizării şi a formei clinice a carcinomului în momentul spitalizării. Pentru studiul histopatologic am avut în vedere următorii parametri: tipul carcinomului cutanat (CBC – carcinom bazocelular, CSC – carcinom spinocelular, de structură anexa a pielii, cu celule Merkel, metastază de carcinom cu altă localizare - MTS); forma histopatologică a carcinomului bazocelular; gradul de diferențiere a carcinomului scuamocelular (bine diferențiat; moderat diferențiat; slab diferențiat; nediferențiat).

REZULTATE

În intervalul ianuarie 2006 - decembrie 2010 au fost spitalizați 308 pacienți cu carcinoame cutanate, din care 56,16% au fost pacienți de sex masculin, femeile reprezentând 43,84%. Majoritatea pacienților (69,80%) au provenit din mediul rural (tab. I).

Carcinoamele cutanate au predominat la pacienți cu vârste cuprinse între 71-80 de ani (32,79%) şi 61-70 de ani (26,62%) (tab.II). Vârsta medie de apariție a bolii a fost de 69,16 ani.

TABELUL I

Distribuția anuală a pacienților în funcție de sex şi mediul de proveniență

An	Femei	Bărbați	Mediu rural	Mediu urban
2006	18	28	31	15
2007	25	48	45	28
2008	32	35	59	8
2009	30	25	37	18
2010	30	37	43	24
Total	**135 (43,84%)**	**173 (56,17%)**	**215 (69,8%)**	**93 (30,2%)**

TABELUL II

Distribuția pacienților pe decade de vârstă

Decadă vârstă	Nr/ (%)
< 40 ani	7 (2,29%)
41-50 ani	16 (5,19%)
51-60 ani	56 (18,18%)
61-70 ani	82 (26,62%)
71-80 ani	101 (32,79%)
> 81 ani	46 (14,93%)

Din cei 308 pacienți luați în studiu, în 82,46% din cazuri au fost prezente carcinoame cutanate cu o singură localizare. Localizările predilecte de dezvoltare a leziunilor cutanate maligne au fost piramida nazală – 28,57% şi regiunea geniană – 23,70%. Alte localizări (regiuni mentonieră, palpebrală, cervicală, periauriculară, parietală etc) au fost reprezentate proporții mult reduse, cuprinse între 2,59% şi 0,39%) (tab.III).

TABELUL III
Localizarea leziunilor carcinomatoase cutanate ale feței

Localizare	Nr/ (%)
Localizare unică	**254 (82,46%)**
Piramida nazală	88 (28,57%)
Regiune genianã	73 (23,70%)
Regiune temporală	31 (10,06%)
Regiune frontală	28 (9,09%)
Regiune maseterină	25 (8,11%)
Regiune labială	24 (7,79%)
Alte localizări	39 (12,68%)
Localizare multiplă	**54 (17,54%)**

Carcinomul bazocelular s-a situat pe primul loc ca frecvență, reprezentând 75,97%, urmat de carcinomul scuamocelular (18,18%) (fig. 1). Alte tipuri de carcinoame cutanate întâlnite, dar în proporții semnificativ mai reduse, au fost carcinoamele cu celule Merkel (0,65%) şi carcinoamele dezvoltate pe structuri anexe al tegumentului, precum şi metastaze cutanate ale unor carcinome cu alte localizări (sân, colon) (tab.IV).

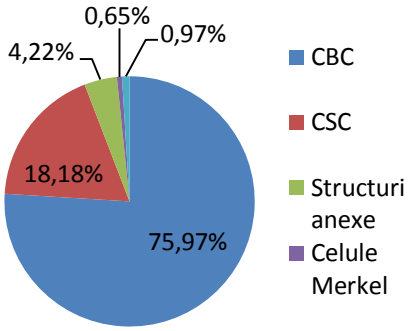

Fig. 1. Distribuția procentuală a carcinoamelor cutanate.

TABELUL IV
Tipuri de carcinoame cutanate

Sex	CBC (nr./%)	CSC (nr./%)	Structuri anexe (nr./%)	Celule Merkel (nr/%)	MTS (nr/%)
F	106 (45,30%)	26 (46,43%)	2 (15,39%)	0	1 (33,34%)
B	128 (54,70%)	30 (53,57%)	11 (84,61%)	2 (100%)	2 (66,66%)
Total	234	56	13	2	3

Din cele 234 cazuri de carcinoame bazocelulare, 54,70% au fost diagnosticate la pacienți de sex masculin, restul de 45,30% fiind reprezentat de sexul feminin. În cadrul carcinoamelor bazocelulare, am întâlnit toate tipurile clinice descrise în literatură: tipul nodular (69,23%), tipul superficial (20,08%), tipul morphea (5,55%) şi pigmentat (5,14%). Examenul histopatologic a confirmat prezența carcinomului bazocelular tip nodular sau solid pe primul loc ca frecvență, dar şi alte forme anatomopatologice, cum ar fi carcinomul bazoscuamos sau metatipic (3,84%), carcinomul bazocelular micronodular (3,41%) sau carcinomul bazocelular keratotic (2,56%). Tipurile polimorfe de carcinoame bazocelulare au fost întâlnite în 3,41% din cazuri (tab. V).

Carcinoamele scuamocelulare au reprezentat 18,18% din totalul leziunilor, cele mai frecvente fiind: ulcero-vegetantă (50%), nodulară (17,85%), verucoasă (17,85%). În funcție de gradul de diferențiere, carcinoamele scuamocelulare bine diferențiate au fost prezente în procent de 32,14%, formele

moderat diferențiate – 42,85%, iar cele slab diferențiate 16,07% (tab. VI).

TABELUL V
Forme clinice şi histopatologice carcinoame bazocelulare

Forme clinice	**Nr (%)**
Nodular	162 (69,23%)
Superficial	147 (20,08%)
Morphea	13 (5,55%)
Pigmentat	12 (5,14%)
Forme histopatologice	**Nr (%)**
Nodular/solid	156 (66,66%)
Superficial	34 (14,52%)
Bazoscuamos	9 (3,84%)
Micronodular	8 (3,41%)
Polimorf	8 (3,41%)
Keratotic	6 (2,56%)
Infiltrativ	5 (2,13%)
Diferențiere anexială	5 (2,13%)
Fibroepitelial	3 (1,34%)

TABELUL VI
Forme clinice şi histopatologice de carcinoame scuamocelulare

Forme clinice	**Nr (%)**
Ulcero-vegetantă	28 (50%)
Nodular	10 (17,85%)
Verucos	10 (17,85%)
Keratozic	8 (14,3%)
Forme histopatologice	**Nr (%)**
Bine diferențiat	18 (32,14%)
Moderat diferențiat	24 (42,85%)
Slab diferențiat	9 (16,07%)
Nediferențiat	5 (8,94%)

Carcinoamele structurilor anexe ale pielii au fost slab reprezentate în lotul de studiu, însumând doar 13 cazuri, adică 4,22%, din care 7 cazuri au fost carcinoame cu diferențiere sebacee, 2 cazuri cu diferențiere ecrină, 2 cazuri cu diferențiere apocrină şi 2 cazuri cu diferențiere foliculară (tab. VII).

TABELUL VII
Carcinoamele structurilor anexe ale pielii

Tipul diferențierii celulare	**Nr (%)**
Sebacee	7 (53,84%)
Apocrină	2 (15,38%)
Ecrină	2 (15,38%)
Foliculară	2 (15,39%)

Carcinomul cu celule Merkel s-a întâlnit în 0,65% din pacienți, iar metastazele cutanate de la carcinoame cu alte localizări în 0,97% din cazuri (fig. 1).

DISCUȚII

Carcinoamele cutanate sunt cele mai frecvente tumori maligne şi datorită creşterii continue a incidenței reprezintă o problemă importantă de sănătate publică. Numărul total al carcinoamelor cutanate diagnosticate anual în Statele Unite este de peste un milion, echivalent cu totalul cazurilor de cancere cu alte localizări (1). În Marea Britanie sunt raportate anual peste 46 000 de cazuri noi de cancer cutanat (2). De asemenea, incidențe foarte mari sunt întâlnite în Australia -1170/100 000 (3). În România cancerul cutanat a reprezentat 10,8% din totalul cancerelor în 2005 (4).

În etiopatogenia carcinoamelor cutanate sunt implicați mai mulți factori. Peste 90% din carcinoamele cutanate ale feței sunt cauzate de expunerea la radiațiile solare (1). În studiul nostru, cei mai mulți pacienți, reprezentând un procent de 69,92%, proveneau din mediul rural, majoritatea cu profesii care presupun expunerea îndelungată la soare (agricultori, grădinari, etc.).

Carcinoamele cutanate se dezvoltă în special la indivizi între a 4-a şi a 8-a decadă de viață, cu o uşoară predilecție pentru sexul masculin. În lotul nostru vârsta medie a fost de 69,16 ani, cele mai multe cazuri (32,79%) aparținând decadei vârstă

71-80 de ani. Raportul bărbaţi/femei a fost de 1,28, apropiat de cel înregistrat în Suedia sau Marea Britanie (5).

Majoritatea autorilor au apreciat că cea mai frecventă localizare a carcinoamelor cutanate este reprezentată de piramida nazală (25-30%), urmată de alte regiuni ale feţei, scalpului şi gâtului (6,7). În studiul nostru, piramida nazală s-a situat pe primul loc – 28,57% (88 cazuri), urmată regiunea genianã – 23,70% (73 cazuri).

Carcinoamele cutanate cu localizări multiple se dezvoltă cel mai adesea pe leziuni cutanate preexistente. Tranziţia de la tegumentul normal la leziunea precanceroasă şi ulterior la neoplazia cutanată se desfăşoară lent, pe durata a mai multor ani. Imunosupresia cronică poate contribui la apariţia tumorilor cutanate multiple, adeseori având o evoluţie agresivă. Într-o serie de afecţiuni determinate genetic, se remarcă o reală predispoziţie pentru dezvoltarea de tumori cutanate maligne multiple, la vârste semnificativ mai tinere decât la indivizii normali. Nevomatoza bazocelulară multiplă, sindromul Rambo, sindromul Bazex, xeroderma pigmentosum, sindromul Cowden includ în tabloul clinic prezenţa carcinoamelor bazocelulare multiple (4,8). În studiul nostru, 54 de pacienţi, reprezentând 17,54% au prezentat leziuni multiple. În 4 cazuri, carcinoamele s-au dezvoltat probabil pe fondul imunosupresiei cronice, deoarece 3 pacienţi au prezentat în antecedente transplanturi renale şi unul dintre ei a urmat tratament cronic cu imunosupresoare timp îndelungat pentru lupus eritematos sistemic. Examenul histopatologic a stabilit diagnosticul de carcinom scuamocelular moderat diferenţiat cu keratinizare redusă, focare de necroză şi ulceraţie întinsă. Cea mai mare parte a carcinoamelor multiple însă s-au dezvoltat pe leziuni preexistente, în special keratoza actinică. Cazurile de carcinoame bazocelulare multiple din lotul de studiu nu au apărut pe fondul unei afecţiuni genetice.

Carcinomul bazocelular se dezvoltă din keratinocitele bazale ale epidermului şi structurilor anexe ale pielii (foliculi piloşi, ductele glandelor sudoripare). Este cea mai frecventă tumoră malignă cutanată, reprezentând aproximativ 75% din carcinoamele cutanate nonmelanocitare (8). În lotul nostru procentul a fost de 75,97%.

Carcinomul bazocelular are mai multe forme clinice, care variază ca aspect clinic şi potenţial malign. Cea mai frecventă este cea nodulară, reprezentând 62-70%, urmată de forma superficială (10%). Forme mai puţin întâlnite sunt carcinomul bazocelular sclerozant sau forma morphea**,** cea mai agresivă formă clinică, precum şi carcinomul pigmentat (7,10). O atenţie specială trebuie acordată carcinomului bazoscuamos sau metatipic, care a constituit de-a lungul timpului subiectul a numeroase controverse. Confuzia derivă din aspectul său histopatologic, cu prezenţa caracteristicilor comune celor două tipuri, bazocelular şi scuamocelular la nivelul aceleiaşi leziuni, de unde şi caracterul imprevizibil al prognosticului şi comportamentului tumorii (8).

În ceea ce priveşte formele clinice ale carcinomului bazocelular, am observat prezenţa în lotul de studiu a tuturor tipurilor clinice citate în literatură, cel mai frecvent întâlnite forme fiind cea nodulară (69,23%) şi superficială (20,08%). De asemeni, am remarcat polimorfismul histopatologic al acestui carcinom, fapt de altfel consemnat în literatura de specialitate. În ordinea descrescătoare a frecvenţei, pe primele locuri am înregistrat următoarele forme histopatologice: carcinom bazocelular nodular/solid (66,66%), carcinom ba-

zocelular superficial (14,52%), carcinom bazoscuamos (3,84%).

Carcinoamele scuamocelulare sunt tumori maligne cu originea în keratinocitele epidermice, dezvoltate cel mai frecvent pe leziuni precursoare, cum este keratoza actinică. Ocupă locul al 2-lea ca frecvență după carcinomul bazocelular, reprezentând peste 20% din totalul tumorilor maligne ale pielii (7). În lotul luat în studiu, carcinoamele scuamocelulare au reprezentat 18,18%. Cele mai întâlnit forme clinice au fost forma ulcerativă (50%), forma nodulară (17,85%) şi forma verucoasă (17,85%). Studiul histopatologic al carcinomului scuamocelular a evidențiat predominența formelor moderat diferențiate (42,85% din cazuri), urmată de forma bine diferențiată (32,14%) şi cea slab diferențiată (16,07%). Aceste date sunt asemănătoare celor desprinse din alte studii (11).

Carcinoamele anexelor pielii prezintă adeseori reale dificultăți de diagnostic pozitiv şi diferențial. În funcție de tipul de diferențiere celulară, tumorile structurilor anexe se clasifică în tumori cu diferențiere apocrină, ecrină, foliculară şi sebacee (12).

Carcinoamele glandelor sudoripare sunt relativ rar întâlnite (2-3 cazuri la 100.000 indivizi) şi manifestă un comportament clinic agresiv (7). În lotul nostru le-am întâlnit în 4 cazuri, reprezentând 30,76% din carcinoamele structurilor anexe ale pielii şi 1,29% din totalul carcinoamelor cutanate. Carcinomul sebaceu este o tumoră agresivă rară cu originea în țesutul epitelial al glandelor sebacee. Tumora apare la indivizii în vârstă, de obicei în decadele 6 şi 8 de viață, având o incidență aproximativ egală la cele două sexe (13,14). În lotul studiat a repezentat 53,84% din carcinoamele structurilor anexe ale tegumentului şi 2,27% din totalul carcinoamelor cutanate luate în studiu.

Carcinomul cu celule Merkel sau carcinomul neuroendocrin cutanat primar este un tip rar de cancer cutanat dezvoltat din celulele Merkel din stratul bazal al epidermului, cu rol de receptori tactili. Incidență este estimată la 0,44 din 100 000 indivizi (6, 15). Am identificat doar 2 cazuri de carcinoame cu celule Merkel, reprezentând 0,65% din totalul carcinoamelor cutanate.

Metastazele cutanate, deşi rare, pot reprezenta primul semn clinic al unei malignități viscerale. Frecvența metastazelor cutanate este corelată la fiecare sex cu tipul tumorii primare. Femeile cu metastaze cutanate prezintă următoarea distribuție a carcinoamelor primare: sân 69%; colon 9%; melanom 5%. La bărbați, distribuția este următoarea: plămân 24%; colon 19%; melanom 13% (16). Am identificat 3 cazuri de metastaze cutanate, în două cazuri tumora primară fiind la nivelul sânului şi într-un caz cu localizare la nivelul colonului.

CONCLUZII

Carcinoamele cutanate sunt cele mai frecvente tumori maligne ale organismului, reprezentând prin morbiditatea crescută şi prin gravitatea potențială o problemă de sănătate publică. Educarea populației pentru cunoaşterea factorilor de risc, cât şi depistarea şi tratamentul precoce al cancerelor cutanate şi al leziunilor precanceroase sunt elemente decisive în managementul acestor leziuni, asigurând rate de vindecare crescute.

Datorită polimorfismului clinic al carcinoamelor cutanate, examenul histopatologic este indispensabil pentru stabilirea diagnosticului de certitudine, în unele cazuri fiind necesare investigațiile imunohistochimice, în special în cazurile cu structură histopatologică particulară.

Disciplina Biomecanică

SCOLIOSIS SCREENING USING PLANTAR PRESSURE ANALYSIS (abstract) : Earlier scoliosis detection is one of the orthopedics and family doctor challenge. Normally, the first observation about a child deformity should be done by the family doctor in order to announce or not the need of special investigations by a specialist. Usually, the so called idiopathic scoliosis is determined by some factor that interfere during the growing period and most of the time a wrong body attitude static and dynamic during daily activities (learning, sleeping, playing, sitting) and/or angular discrepancy or limb length discrepancy. **Material and method :** All those factors effects can be seen in a plantar pressure analysis evaluation witch soft give us information about the center of gravity of the body and the pressure on the foot that can be correlate in order to discover any articulation imbalance, even the spine deformity. **Results** : It has been demonstrated through algorithms and case studies that a specific pattern of the plantar pressure analysis image is characteristic for the scoliotic persons. **Key words** : SCOLIOSIS, PODOLOGY, PRESSURE

Scolioza reprezintă deformările şi încurbările coloanei vertebrale în forma literei S sau a literei C. Devierea se petrece în plan frontal, dar se şi poate răsuci în jurul axului. Mulţi oameni au deviaţii uşoare ale coloanei vertebrale, dar nu sunt considerate a fi scolioze în cazurile în care curburile au mai puţin de 10 grade. Scolioza apare îndeosebi la nivelul coloanei toracice (în partea de mijloc a spatelui) sau la nivelul coloanei lombare (în partea de jos a spatelui). Dacă deviaţiile sunt mari, atunci pot apărea dureri disconfortante şi dificultăţi mari în respiraţie. La copii, deformările coloanei vertebrale care se concretizează cu timpul în scolioze, se produc în timpul copilăriei, între 9 şi 11 ani. Medicii specialişti susţin că deformările coloanei vertebrale sunt în strânsă legătură cu primii ani de şcoală, adică primii ani de stat în bancă perioade mai lungi de timp. Aceştia afirmă că scolioza este determinată de poziţia pe care o adoptă copilul în bancă în timpul orelor petrecute la şcoală.

La ora actuala evaluarea coloanei se face de către medicul ortoped la solicitarea parintelui sau a medicului de familie care observă o deformaţie a coloanei masurabilă cu scoliometrul sau radiologic. Nu există metodă de evaluare fără a dezbraca pacientul şi a-l observa. În al doilea rând, nici o altă metodă nu corelează inegalităţi ale sistemului osteoarticular cu prezenţa scoliozei (1).

MATERIAL ŞI METODĂ

În această lucrare se urmăreşte diagnosticarea scoliozei utilizând analiza plantară, o metodă modernă şi, în acelaşi timp eficientă.

Analiza plantară computerizată reprezintă una din tehnicile performante de identificare a zonelor de presiune de la nivelul piciorului (2,3). Testarea se realizează în statică şi/sau dinamică, prin contactul cu o platformă cu senzori de presiune, care preia

informaţiile de la nivelul piciorului şi le transpune prin intermediului unui soft specializat într-o imagine (1 : 1). Complexitatea programului ne permite stocarea unei baze de date a pacienţilor testaţi, putându-se analiza nu numai amprenta plantară ci şi mersul, uzura încălţămintei, postura întregului corp, facilitându-se, astfel, urmărirea evoluţiei pacienţilor (4,5).

În studiul prezentat în această lucrare, metoda de evaluare, a pacienţilor cu scolioză, presupune folosirea unei o plăci matriceale tip LorAn Engineering Sistema EPS-C, cu senzori de presiune şi soft de redare a presiunilor la nivelul plantei cu posibilitatea trasării graficului de repartiţie a centrului de greutate a corpului, la nivelul poligonului de susţinere.

Placa de presiune are o suprafaţă de 50cm $\times$50 cm cu 2500 de senzori cu timp de înregistrare setabil de minim 5 secunde. Poziţia centrului de greutate poate fi vizualizată atât statistic prin cumul total, cât şi punctual, în regim dinamic frame by frame.

În scopul diagnosticării scoliozei s-a realizat un algoritm de studiu, care constă în evidenţierea repartiţiei presiunilor plantare cae să fie caracteristică acestrui tip de deformare a coloanei vertebrale.

S-au luat în calcul modelele de deviaţie a centrului de greutate a corpului în funcţie de diferite inegalităţi ale sistemului osteoarticular.

S-a ţinut cont de deviaţiile în cele trei axe ale segmentelor corpului, în cazul diferitelor tipuri de scolioză, interpretarea luând în consideraţie deviaţiile în ambele sensuri, de sus în jos şi de jos în sus.

În regim static, scolioza este asociată cu deviaţiile clasice cele mai frecvente care stau la baza dezvoltarii acesteia : valg călcâi unilateral, metatars adductus unilateral, valg/var genunchi unilateral, rotaţie de gambă, rotaţie de femur, anteversie col femural, scurtare reală de membru, antecedente în articulaţia şoldului (displazie de şold unilaterală incomplet redusă), dezechilibru muscular între adductori şi abductori.

În regim dinamic, factorii care redau o scolioză, dar care nu stau la baza unor inegalităţi osteoarticulare, sunt parezele musculare şi hemiplagiile.

Deviaţiile datorate deformaţiei coloanei sunt : translaţie de bazin, înclinare de trunchi, modificare a poziţiei centurii scapulare, modificarea curburii costale pe diagonală, înclinaţia bazinului, rotaţia trunchiului faţă de bazin, false scurtări.

PROTOCOL EXPERIMENTAL

S-au efectuat 520 de amprente plantare la copii cu vârste cuprinse între 4 şi 18 ani. S-a ţinut cont de vârsta de 4 ani considerată vârsta pâna la care deviaţiile în ax ale piciorului sunt normale. În acest sens, s-au efectuat 50 de analize pe copii cu vârsta sub 4 ani, care s-au dovedit neconcludente datorită incapacităţii de a menţine copilul cu ambele picioare pe placă, (peste 50% dintre copii mişcau unul din membre în timpul înregistrării).

Pentru comparaţie, toţi pacienţii au fost verificaţi cu scoliometrul şi prin teste specifice care să determine deviaţia coloanei : metoda verificării cu firul de plumb, evaluare vizuală din poziţia aplecat la 90 de grade, radiografii (pentru cazurile mai grave).

S-au luat în calcul toate deviaţiile osteoarticulare posibile, astfel încât pacienţii suspectaţi că ar avea şi alte deviaţii decât cele ale piciorului şi coloanei, au fost verificaţi la nivelul genunchiului şi soldului prin măsurători goniometrice şi dinamice.

Primele caracteristici ale prezenţei scoliozei au fost determinate prin observarea unei diferenţe de presiuni plantare între membrul inferior stâng şi cel drept şi între raportul de reparţitie al presiunii atât între calcâiul drept şi cel stang, cât şi între antepiciorul drept şi cel stang.

REZULTATE ŞI DISCUŢII

Vor fi analizate, în cele ce urmează,

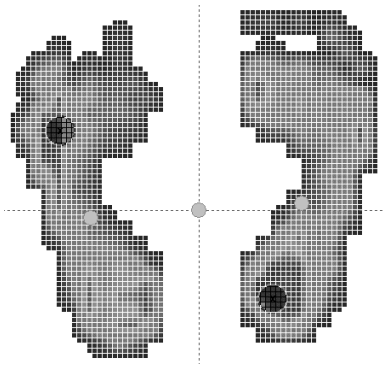

Fig. 1. Distribuţia de presiuni în urma analizei plantare (E. B. 8 ani ♀). Valorile maxime, ale presiunii, se înregistrează la nivelul antepicioarului stâng şi retropiciorului drept (cercurile mari)

două modele ale distribuţiei de presiuni la nivel plantar, corespunzătoare la două cazuri care sunt concludente în stabilirea diagnosticului de scolioză. Masurătorile au scos în evidenţă fasptul ca la nici unul dintre cele două cazuri nu sunt prezente deformaţii la nivelul articulaţiilor şoldului, genunchiului şi gleznei.

Un prim caz (E. B. 8 ani ♀) ale cărui rezultate, în urma analizei plantare, sunt ilustrate în fig. 1, relevă faptul că pacientul este perfect compensat, în sensul în care diferenţa presiunilor medii (în procente din valoarea medie a presiunii pe întreaga suprafaţă de sprijin) dintre piciorul stâng şi cel drept, este aproximativ egală: 49,5%/50,5%, (fig. 1.B). De asemenea, se observă că suprafeţele de contact diferă cu 1 cm^2 (105,0 cm^2 stanga şi 104,0 cm^2 dreapta) iar presiunile medii au valorile 0,9 kgf/cm^2 (stânga) şi 1 kgf/cm^2 (dreapta). Se poate trage concluzia că forţa echivalentă care acţionează pe piciorul stâng este de 94,5 kgf (927 N) iar pe piciorul drept este de 104 kgf (1020 N), astfel, se poate trage concluzia că că glezna dreaptă este mai încărcată decât glezna stângă. Cu alte cuvinte centrul de greutate al corpului va fi deplasat spre dreapta-posterior, coloana fiind curbată în aceeaşi direcţie.

Dacă, în schimb, se ia în consideraţie

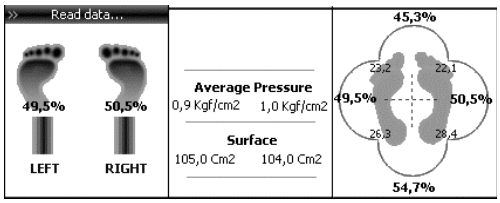

Fig. 2. Distribuţia presiunilor, în valori procentuale şi în valori reale, pentru piciorul stâng şi piciorul drept, şi valorile presiunilor în procente pentru fiecare antepicior şi retropicior în parte, corespunzătoare cadranului suprafeţei de sprijin (E. B. 8 ani ♀).

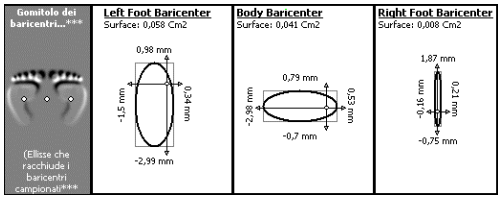

Fig. 3. Poziţia baricentrelor pentru: piciorul stâng, întreaga suprafaţă de sprijin şi piciorul drept (E. B. 8 ani ♀).

repartiţia presiunilor defalcată pe zonele reprezentate de retropicior şi antepicior se observă că distribuţia acestora se situează pe două diagonale: valorile mari pe o diagonală, valorile mici pe cealaltă diagonală, altfel spus, valorile mici sunt pe diagonala calcâi stâng şi antepicior drept şi valorile mari sunt pe diagonala ale calcâi drept şi antepicior stâng (fig. 1). Dacă se face suma presiunilor pentru un picior pe axul retropicior–antepicior, se observă că diferenţa este destul de mică de 1% (49,5%/50,5%), dar dacă se calculează pe cele două diagonale, se obţine o diferenţă semnificativă de 3,2% (48,4%/51,6%), ceea ce ilustrează, de asemenea, un dezechilibru (fig. 2).

O altă variabilă, care poate da informaţii cu privire la prezenţa scoliozei, este graficul rezultat prin unirea punctelor poziţiei baricentrelor corespunzătoare: piciorului sting, a întregului corp corp, picior drept, care este reprezentat de o linie descendentă

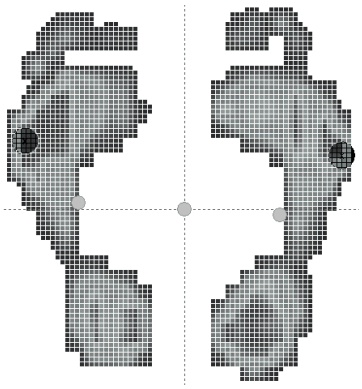

Fig. 4. Distribuţia de presiuni în urma analizei plantare (R. C. 10 ani ♀). Valorile maxime, ale presiunii, se înregistrează la nivelul antepiciorului stâng şi antepiciorului drept (cercurile mari).

(fig. 3). O astfel de diagramă este valabilă în cazul scoliozelor clare.

S-a observat că, cu cât panta baricentrelor este mai mare, cu atât rotaţia în ax şi, implicit, scolioza este mai acentuată.

Pentru cel de al doilea caz (R. C. 10 ani ♀), distribuţia de presiuni plantare este ilustrată în fig. 4. Spre deosebire de cazul anterior, diferenţa presiunilor medii, în procente, dintre piciorul stâng şi cel drept, este destul de mare: 47,3%/52,7%, (fig. 4). Suprafeţele de contact înregistrază, de asemenea, diferenţe semnificative: 97,0 cm^2 (stânga) şi 102,0 cm^2, mai mici decât în primul caz. Presiunile medii, în schimb, au valori sensibil egale (1,2 kgf/cm^2 (stânga) şi 1,3 kgf/cm^2 (dreapta)). Forţele echivalente pentru fiecare picior în parte sunt: 116,4 kgf (1142 N) pentru piciorul stâng şi 132,6 kgf (1301 N) pentru piciorul drept, aceste date ilustrând faptul că glezna dreaptă este mai încărcată decât glezna stângă cu aproximativ 14%, deci, centrul de greutate al organismului este deplasat spre dreapta-anterior, iar coloana este înclinată în acelaşi sens.

Presiunile (în procente din presiunea medie pe întreaga suprafaţă de sprijin) pentru antepicior şi retropicior ilustrează un dezechilibru pentru acelaşi picior, suma pe axul retropicior-antepicior fiind diferită pentru cele două picioare 43,7% pentru stângul şi 52,7% pentru dreptul. Acest dezechilibru este dat de diferenţa mare de presiuni existentă la nivelul călcâielor: 17,8% pentru stângul şi 23,25% pentru dreptul. La nivelul antepiciorului, presiunile sunt sensibil egale: 29,6% pentru stângul şi 29,5% pentru dreptul, astfel încât, se formează, şi în acest caz, două diagonale, o diagonală de presiune maximă retropicior drept – antepicior stâng şi o diagonală de presiune minimă retropicior stâng – antepicior drept (fig. 5).

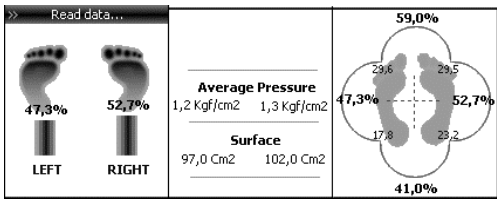

Fig. 5. Distribuţia presiunilor, în valori procentuale şi în valori reale, pentru piciorul stâng şi piciorul drept, şi valorile presiunilor în procente pentru fiecare antepicior şi retropicior în parte, corespunzătoare cadranului suprafeţei de sprijin (R. C. 10 ani ♀).

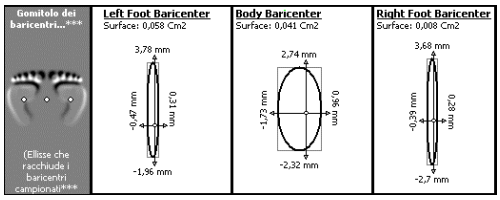

Fig. 6. Poziţia baricentrelor pentru: piciorul stâng, întreaga suprafaţă de sprijin şi piciorul drept (R. C. 10 ani ♀).

De asemenea este semnificativă şi poziţionarea baricentrelor. Se observă că presiunile maxime sunt dispuse anterior, baricentrele din fig. 6 sunt deplasate spre dreapta, dar înclinarea dreptei care este reprezentată de unirea acestora, nu este atât de accentuată precum în cazul anterior.

În acestă situaţie, atitudinea scoliotiocă este cu atât mai evidentă cu cât valorile presiunilor pe antepicior sunt aproape identice, dar diferă cu 4,4% între calcâie.

CONCLUZII

Prezenţa deformaţiilor coloanei vertebrale au influenţă directă asupra distribuţiei presiunilor plantare, fapt confirmat de măsurătorile efectuate pe cei 520 pacienţi şi, implicit, de cele două cazuri prezentate în această lucrare.

Datele culese şi prezentate în această lucrare au condus la concluzia că există două variabile care dau verdictul de „risc de scolioza" : repartiţia pe diagonala a presiunilor maxime şi diferenţa dintre suma presiunilor pe : diagonalele şi/sau pe verticala cadranelor.

Repartiţia baricentrelor pe diagonală, indică o deviaţie în ax a coloanei.

Linia baricentrelor poate fi orizontală, dar cu baricentrele deplasate spre dreapta sau spre stânga (în cazul atitudinilor scoliotice fără deformaţie în C sau S), ceea ce indică o înclinare a coloanei în direcţia deplasării baricentrelor.

Metoda prezentată poate fi aplicată şi în cazul unor alte deformaţii ale coloanei, precum lordoză sau cifoză.

SEM COMPARATIVE ANALYSIS OF THE COMPOSITE DIACRYLIC RESIN-ENAMEL INTERFACE IN LASER AND BUR PREPARED CAVITIES (Abstract): The aim of this study was to demonstrate that the size of the hybrid layer (HL) in the prepared enamel mechanic (M) and kinetic (K) with laser (WaterlaseMDBiolase), evaluated by scanning electron microscopy (SEM) restored with two types of resin composite is different. **Material and method**: The study was realized *in vitro* on a sample of 40 extracted human premolar and molars teeth for orthodontic or periodontal reasons. The teeth were divided at random into equal four groups (Gr). There has been Class I cavities with a depth of 2 mm (M) at high and low speed with cylindrical diamond No.1 and globular carbide and (K) peaks MZ6-5, 5W+20 Hz 30% water 60% air. The teeth were restored using 3M™ Schotchbond Etch, 3M™Single Bond Dental Adhesive System: Gr.1: (K)(n=10)-3M™Filtekflow; Gr.2: (K)(n=10)3M™FiltekZ250; Gr.3: (M)(n=10)3M™Filtekflow; Gr.4: (M)(n=10)3M™FiltekZ250. The materials were placed in a single layer and photoactivate source LED SmartLite (Dentsply), termocycling 500cycles (5^0-55^0), stored (48h), cut lengthwise (diamond), polished, conditioned (H3PO4-37% -5s) analyzed by SEM (JEOLJSM 6390), SPSS 13.00 statistically analyzed (ANOVA, p = 0.05). **Results**: Analysis of the (HL) has highlighted differences between groups p = 0.05 average size (HL) being Gr.1; 20.80 (± 0.72)μm, Gr.2; 4.034 (± 0.0076)μm,, Gr.3, 14.13 (± 0.63)μm, Gr.4, 1,43 (± 0.16)μm. Value size (HL) was influenced by the cavity preparation method for samples prepared by laser p=0,005 in terms of size and in advantage of mechanical preparations in terms of quality (HL). Also the value of (HL) size was influenced by the type of material used in advance Gr.2 p= 0.0017. **Conclusions**: The sealing of cavity depends more on the creep of materials and less on the type of preparation. Permission was obtained from a institutional ethical committee of "Gr.T. Popa" University of Medicine and Pharmacy Iaşi and that subjects gave written, informed consent). Founding source: CNCSIS-Project: No. 2669/2008. **Key words**: COMPOSITE RESIN, LASER, SEM.

Scopul acestui studiu a fost analiza comparativă prin microscopie electronică cu baleiaj a stratului hibrid în cavităţi de clasa a I-a preparate mecanic(M) şi kinetic (K) – LASER (WaterlaseMD-Biolase), restaurate cu răşină compozită hibridă 3M™ Filtek Z250 si Filtek flow 3M™.

MATERIAL ŞI METODĂ

Studiul a fost realizat "in vitro" pe 40 de dinţi umani premolari şi molari, extraşi prin obţinerea consimţământului informat al acestora din motive ortodontice sau parodontale.

TABELUL I

Dinţii au fost împărţiţi în mod aleatoriu în două grupuri egale la care s-au realizat cavităţi de clasa I de formă dreptunghiulară cu o profunzime de 2mm acţionate în interiorul unui şablon pentru a obţine cavităţi de volum aproximativ egal : Gr. 1,2 - cavităţi preparate mecanic la viteze înalte şi joase cu freze diamantate cilindrice şi freze extradure globulare nr.1 şi Gr. 3,4 – cavităţi preparate kinetic - laser(Waterlase Biolase MD) cu vârfuri de zirconiu MZ6-5, la 5W+20 Hz cu 30% apă si 60% aer acţionate de asemenea în interiorul unui şablon. Materialele de restaurare utilizate au fost : 3M™ Filtek Z250 ESPE), 3M ™Schotchbond etchant, 3M ™ Single Bond Dental Adhesive System. Pentru fotoactivarea materialelor s-a utilizat sursa de fotoactivare luminoasă LED SmartLite (Dentsply). Obturarea dinţilor s-a realizat astfel : Gr.1 : (K) (n=10)-3M™Filtekflow ; Gr.2 : (K)(n=10) 3M™FiltekZ250 ; Gr.3 : (M)(n=10)3M™ Filtekflow ; Gr.4 : (M)(n=10)3M™Filtek Z250. Probele au fost termociclate 500cicli (5^0-55^0) şi păstrate în flacoane cu ser fiziologic până la prepararea probelor pentru analiză (maxim 48 de ore), apoi au fost secţionaţi longitudinal cu discuri diamantate, spălaţi cu alcool de 90^0 pentru a îndepărta stratul de răşină nepolimerizată. Secţiunile rezultate au fost prelucrate şi lustruite cu discuri de hârtie, gume şi paste abrazive cu granulaţie descrescătoare, spălate cu apă distilată timp de 2 minute, demineralizate superficial cu H3PO4 35% timp de 5 secunde pentru a se îndepărta smear-layerul şi au fost apoi spălate timp de 2 minute cu apă distilată. Analiza probelor s-a realizat prin microscopie electronică scanată SEM (JEOLJSM 6390A) iar rezultatele au fost procesate cu ajutorul programului SPSS 14.0 pentru Windows şi a testului statistic ANOVA la un prag de semnificaţie de $p = 0.05$.

REZULTATE

Analiza ultrastructurală a stratului hibrid a pus în evidenţă diferenţe semnificative din punct de vedere statistic între grupuri $p = 0.05$, media dimensiunii stratului hibrid fiind de 20.80 ($\pm$ 0.72)μm pentru Gr.1 de 4.034 ($\pm$ 0.0076)μm pentru Gr. 2, de 14.13 ($\pm$ 0.63)μm pentru Gr. 3 şi de 1,43 ($\pm$ 0.16)μm pentru Gr.4 : (Tab. I, II, III, Fig.1). De asemenea grosimea stratului hibrid a fost influenţată de tipul de material de obturaţie utilizat, Gr. 2 prezentând valorile cele mai bune $p= 0.0017$.

Aspectul interfeţei smalţ - răşină compozită în cavităţi preparate cu LASER : A- GR.1 SEM X 1300–interfaţa smalţ/ compozit Filtek flow (3MESPE). Se observă o intricare optimă a materialului în substructura dentară cu o grosime crescută a stratului hibrid ; B- GR.2 SEM X 3300–inter-

DISCUŢII

Adeziunea biomaterialelor la structurile dure dentare este rezultatul combinării mai multor mecanisme realizându-se o adeziune chimică (legături primare între adeziv si aderent), adeziune fizică (legături secundare, eficientă când distanţa dintre materiale este foarte mică) şi adeziune mecanică (penetrarea materialului în structurile dure dentare la nivel micrometric sau chiar nanometric. Evaluând capacitatea de intricare a materialului de obturaţie în substructura

dentară am concluzionat că materialul 3M™ Filtekflow realizează o grosime a stratului hibrid mult mai mare în comparaţie cu 3M™ FiltekZ250 : 20,80 (laser) şi 14,31 (mecanic) faţă de 4,03 (laser) şi 1,43 (mecanic) (Fig.2,3).

Studiul nostru a arătat că dimensiunea stratului hibrid a fost influenţată de metoda de preparare a smalţului, cavităţile preparate cu laser (Waterlase Biolase MD) prezentând o intricare optimă.

Din punct de vedere calitativ am concluzionat faptul că prepararea mecanică spre deosebire de cea laser a determinat obţinerea unui strat hibrid uniform distribuit la nivelul interfeţei RDC-smalţ, cavităţile preparate fiind astfel mai puţin susceptibile la microinfiltraţie. Rezultatele obţinute sunt susţinute de alte studii de specialitate care au evidenţiat că prepararea laser nu creşte adeziunea materialelor de obturaţie la smalţ şi nici nu ajută la scăderea gradului de microinfiltraţie (1,2,3).

În ceea ce priveşte microinfiltraţia diferitor materiale de restaurare cu structură nanometrică aplicate în cavităţi de clasa V preparate prin metode mecanice şi kinetice--laser, studiile internaţionale au demonstrat faptul că aceasta a fost mai mare la nivelul cavităţilor preparate cu laser decât cea de la nivelul cavităţilor preparate mecanic, indiferent de materialul de obturaţie utilizat (4,5).

Rezultatele prezentate mai sus sunt contrazise de studiul realizat de Yazici în 2009 care susţinea că prin ambele metode de preparare, mecanic şi kinetic, s-au realizat cavităţi care s-au comportat similar, cu rezultate excelente (6).

CONCLUZII

Permeabilitatea tisulară şi gradul de difuzibilitate a materialului reprezintă factori esenţiali pentru hibridizarea răşinilor în smalţ. Studiul nostru a evidenţiat faptul că sigilarea cavităţilor depinde mai mult de capacitatea de intricare a materialului de obturaţie în substructura dentară decât de tipul preparaţiei.

Variaţii ale morfologiei stratului hibrid au fost puse în evidenţă între grupuri dar şi în cadrul aceluiaşi grup la nivelul fiecărei mostre.

Indiferent de grupul studiat, adeziunea la smalţ s-a dovedit optimă din punct de vedere calitativ, prezenţa dehiscenţelor şi a stratului hibrid inconstant remarcându-se în special în cazul probelor preparate cu laser.

Facultatea de Medicină
2. Disciplina de Asistenţa Primară a Stării de Sănătate şi Epidemiologie

CONSIDERATIONS ON DEATH BY DOMESTIC VIOLENCE IN NEAMT COUNTY, BETWEEN 1997-2008 (Abstract): **Material and methods**: The study include a series of 132 cases of domestic violence (DV) accounting for 58% of the 228 homicides recorded between 1997 and 2008 in the Neamt county. Data were processed and interpreted based on epidemiological, statistic and mathematical computer-based methods. **Results**: In 1998, in the Neamt county, 0.69‰ homicides were recorded as compared to 2.56 at country level. In 2000, the rate of homicides by DV had significantly increased, reaching 12.3‰, compared to 4.5‰ at the national level. The prevalence of homicides by DV, according to environment, gender, age groups and other features is presented. **Conclusions**: Domestic violence is hard to control, this phenomenon being uncommon to Romanian society, but represents a major social and public health problem. **Key words**: DOMESTIC VIOLENCE, AGGRESSION, PUBLIC HEALTH PROBLEM, FORENSIC MEDICINE

Violenţa domestică (VD) este un fenomen care a însoţit dintotdeauna construirea şi dinamica familiei, dar includerea ei în atenţia ştiinţelor juridice şi sociale este de dată recentă. Doar în ultimii 20 de ani, ştiinţele sociale şi reglementările legale internaţionale fac referinţă la VD (1,2,3,4).

În prezent, se consideră că VD însumează efectele unor factori sociali şi psihologici: sărăcie, deficienţe ale puterii socio-politice, promovarea în mass media a violenţei faţă de femei, ideologia dominanţei şi agresivităţii masculine (5,6,7,8).

MATERIAL ŞI METODE

Studiul nostru a inclus un lot de 132 cazuri de VD, reprezentând 58% din cele 228 omucideri înregistrate în judeţul Neamţ, în perioada 1997-2008. Informaţiile au provenit din evidenţele Serviciului de Medicină Legală (SML) şi ale Institutului Naţional de Medicină Legală „Mina Minovici" (fig. 1). Prelucrarea şi interpretarea rezultatelor s-au realizat prin metode epidemiologice, statistico-matematice şi computerizate.

REZULTATE ŞI DISCUŢII

1. Analiza repartiţiei anuale a omuciderilor prin violenţă familială, în judeţul Neamţ, comparativ cu situaţia la nivel naţional. În anul 1998, în judeţul Neamţ, s-au înregistrat 0,69‰ omucideri, faţă de 2,56 la nivel naţional. Evaluarea pentru perioada 1998-2000 a evidenţiat o creştere semnificativă ($p < 0,05$) în anul 2000, a ratei omuciderilor prin VD, aceasta ajungând la 12,3‰ locuitori în judeţul Neamţ, comparative cu 4,5‰ pe întreaga ţară.

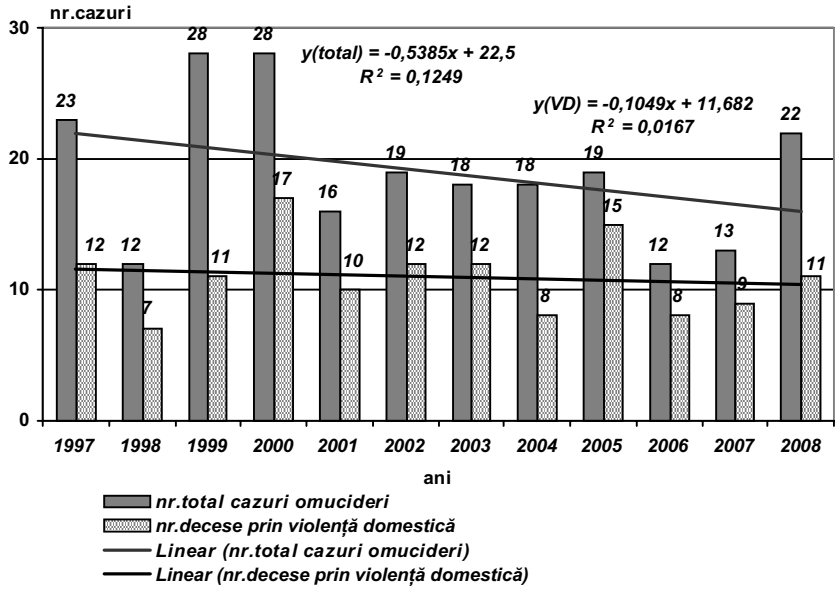

Fig. 1. Repartiţia anuală a deceselor produse prin violenţă familială, înregistrate la SML Neamţ, în perioada 1997-2008

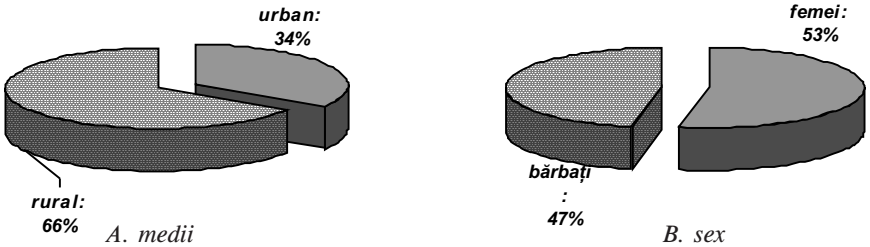
Raportat la numărul total de omucideri, din judeţul Neamţ, în perioada luată în studiu, procentul victimelor a variat între 39% în anul 1999 şi 79% în 2005, cu o medie a intervalului de 58%.

2. Repartiţia pe medii de reşedinţă şi sex. Din totalul omuciderilor prin VD, 34% au provenit din urban şi 66% din rural, 53% femei şi 47% bărbaţi. Forţa fizică mai scăzută a femeilor, implicit, posibilităţilor lor mai reduse de apărare în faţa agresorului fac ca numărul deceselor femeilor victime ale partenerilor de viaţă să fie mai mare. Bărbaţii decedaţi ca urmare a agresiunilor domestice au fost victime atât ale partenerelor de viaţă (soţii, concubine), cât şi ale părinţilor, fiilor, fraţilor, altor rude (cumnaţi, veri) (8,9,10) (fig. 2).

3. Repartiţia pe grupuri de vârstă. Victimele cuprinse în lotul de studiu au avut vârsta între 3 luni şi 83 ani, cele mai multe, respectiv 72 (54%) aparţinând persoanelor active social, cu vârsta între 21 şi 60 ani ($p < 0,05$). Victimele din categoria copii şi tineri au totalizat 7%, iar vârstnicii din propriile familii au reprezentat 22% din totalul omuciderilor prin VD (fig. 3).

4. Distribuţia sezonieră. Numărul cel mai mare a cazurilor de omor urmare a VD s-a înregistrat în lunile ianuarie (15%) şi



A. medii *B. sex*

Fig. 2. Repartiţia pe medii (A.) şi sex (B.) a omuciderilor urmare a violenţei domestice, în judeţul Neamţ, în perioada 1997-2008

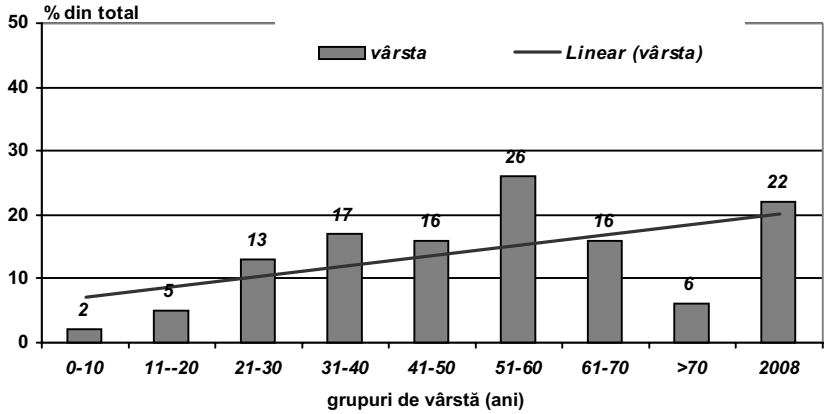


Fig. 3. Repartiţia pe grupuri de vârstă a 132 omucideri prin violenţă domestică, înregistrate în judeţul Neamţ, în perioada 1997-2008

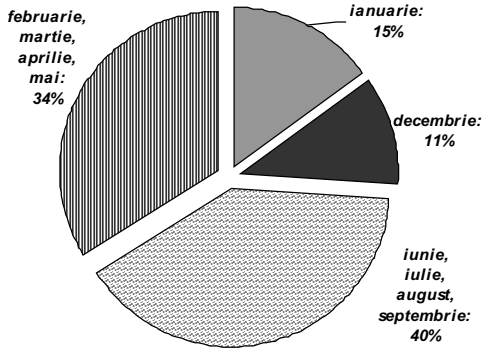

Fig. 4. Distribuţia sezonieră a omuciderilor prin violenţă domestică, înregistrate în judeţul Neamţ, în perioada 1997-2008

decembrie (11%), în principal, asociate consumului de alcool din perioada sărbătorilor de iarnă. În lunile mai, iunie, iulie şi august, au fost raportate 53 cazuri (40% din total) şi 34% în celelalte luni ale anului (fig. 4).

5. Alte caracteristici

5. 1. Examenele toxicologice efectuate pe probele de sânge recoltate de la cadavre au relevat faptul că în 90 de cazuri (68%), victimele consumaseră alcool, având valori ale alcoolemiei de 0,4-3,5%. La acestea, se mai adaugă cazurile la care consumul de alcool s-a stabilit prin prezenţa halenei alcoolice şi cele la care autopsia s-a practicat după 24 ore de la spitalizare.

5. 2. Relaţia victimă-agresor. Ancheta a evidenţiat că 63 (48%) din cazuri au fost victimele soţului sau concubinului, urmate de fiu-părinte (inclusiv ginere-noră) în 45 (34%), de fraţi (inclusiv frate adoptiv) – 16 (12%), alte rude – 8 (6%) şi 5 (3,8%) agresiunea a antrenat mai mulţi membri ai familiei (tab. I).

5. 3. Mijloacele de atac folosite de agresori au inclus: lovire cu pumnii, picioarele, capul, muşcare, comprimare cu propriul corp, strangulare în 34 (26%); lovire cu corpuri dure tăioase (cuţit, ciob de sticlă, topor, secure) – 40 (30%); lovire cu corpuri dure

TABELUL I

Natura relaţiei dintre victimă-agresor în omuciderile incluse în studiu, în judeţul Neamţ, în perioada 1997-2008

TABELUL III

Cauza medicală a decesului victimelor violenţei domestice, în lotul studiat, în judeţul Neamţ, în perioada 1997-2008

Cauza medicală a morţii	Nr. cazuri	%
Traumatismul cranio-cerebral sau vertebro-medular	33	25
Asfixia	13	10
Hemoragia	36	27
Şocul	23	17
Insuficienţa cardio-respiratorie acută	27	19
Total	**132**	**100**

netăioase – 18 (14%); arsuri cu obiecte sau împuşcarea – 3 (2%); substanţe caustice – 3 (2%); combinarea mai multor mijloace – 30 (23%) (tab. II).

5. 4. Tabloul lezional prezentat de victimele VD a fost deosebit de variat: în 15 (13%) leziunea a fost unică (plagă penetrantă urmată de o hemoragie internă sau externă). În celelalte cazuri, victimele au prezentat multiple leziuni situate pe toată suprafaţa corporală: echimoze, excoriaţii, plăgi, fracturi osoase, contuzii grave cu lezarea unor organe interne, arsuri cu lichide sau obiecte fierbinţi, substanţe chimice etc.; în 4 (3%) din cazuri, victimele au fost şi violate de către agresori.

În 33 (25%) din cazuri, decesul s-a produs urmare a unui traumatism cranio-cerebral sau vertebro-medular, cu leziuni grave ale creierului, măduvei spinării sau meningelor; în 13 (10%) a intervenit asfixia (prin comprimarea gâtului, toracelui, abdomenului sau prin aspirat sangvin în căile respiratorii); hemoragia internă sau externă a produs decesul a 36 (27%) dintre victime; şocul (traumatic, hemoragic, septic) în 25 (17%); insuficienţa cardio-respiratorie acută în 27 (19%) din total cazuri (tab. III).

CONCLUZII

Se poate aprecia că fenomenul VD este unul periculos şi greu de controlat şi, totodată, dificil de surprins în statisticile oficiale. Departe de a fi o particularitate a societăţii româneşti, VD este o problemă socială şi de sănătate populaţională, care cumulează efectele intervenţiei unor factori sociali şi psihologici. Prevalenţa actelor de VD a înregistrat o creştere alarmantă, în contextul unei societăţi generatoare de nemulţumiri şi frustrări.

Violenţa fizică şi consecinţa sa extremă, decesul victimei, şochează prin existenţa unui număr semnificativ de mare a situaţiilor în care un om poate fi ucis de un membru al familiei sale.

NOUTĂŢI

EROZIUNILE DENTARE LA PACIENŢII CU REFLUX GASTRO-ESOFAGIAN CU SIMPTOME RESPIRATORII

Atât eroziunile dentare cât şi simptomele respiratorii de tipul tusei nocturne, astmului, laringitei, sunt strâns corelate cu refluxul gastro-esofagian. Tutuşi puţine studii au investigat corelaţia dintre cele două tipuri de patologii. Autorii au efectuat studiul pe trei loturi de pacienţi cu reflux gastro-esofagian, selectate în funcţie de frecvenţa simptomelor respiratorii. Eroziunile dentare au fost evaluate utilizând indicele modificat de uzură dentară (Smith şi Knight). Rezultatele studiului au demonstrat că pacienţii cu reflux gastro-esofagian prezintă eroziuni dentare variind de la gradul 1 la 4, frecvenţa acestor leziuni fiind semnificativ mai mare în cazul celor cu simptome respiratorii frecvente (64,52%) comparativ cu cei care prezintă ocazional sau de loc aceste simptome (44,4%, respectiv 36,67%). Gravitatea eroziunilor, evaluată prin valorile indicilor de uzură dentară, s-a corelat de asemenea pozitiv cu frecvenţa simptomatologiei respiratorii. La pacienţii cu simptome respiratorii, refluxul vaporilor şi gazului gastric contribuie alături de refluxul lichidelor şi solidelor, la instalarea patologiei dentare. Fenomenul de microaspirare este mai puternic iar vaporii acizi ajung la nivelul faringelui şi cavităţii orale, determinând efecte importante chiar şi în cazul unor cantităţi mici de acid. Medicamentele utilizate de aceşti pacienţi pot contribui într-o măsură mai mică la agravarea eroziunilor. Aceste rezultate atrag atenţia asupra riscului crescut de eroziune dentară la pacienţii cu reflux gastro-esofagian însoţit de simptome respiratorii şi asupra necesităţii de a introduce măsuri preventive adevate la această grupă de risc (Wang G-R, Zhang H, Wang Z-G, Jiang G-S, Guo C-H. Relationship between dental erosion and respiratory symptoms in patiens with gastro-oesophageal reflux disease. *J Dentist* 2010 ; 38 : 892-898).

EVALUAREA FEEDBACK-ULUI POSTTERAPEUTIC ÎN REABILITAREA ORALĂ ÎN ACORD CU DIFERITELE METODE DE AMPRENTARE

Cătălina Gârbea, Magda Ecaterina Antohe, Norina Consuela Forna
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină Dentară
Clinica şi Terapia Edentaţiei Parţiale Întinse

POSTTHERAPEUTIC FEED-BACK EVALUATION IN ORAL REHABILITATION (Abstract): The goal of this study was to assess the subjective post-therapeutic feedback for a group of patients in order to evaluate the possibility of including the psycho-behavioral parameters into the analysis structure of an expert system. **Material and method:** 135 patients diagnosed with class I and II Kennedy edentation, aged between 40 and 89 years old, where clinically examined. All patients filled in structured questionnaires focused on psycho-behavioral parameters. **Results:** Prosthetic treatment in oral rehabilitation improves subjective perception of facial aesthetic (66,86% total and moderate accord), psychological status (71.14% total and moderate accord) and of the social relations (77.47% total, moderate and low accord) but it is not subjective associated with the improving of general health (55.49% disagreement). **Conclusions:** We can establish statistical support correlation between psycho-behavioral parameters and therapeutic solutions applied in oral rehabilitation, correlation that can be later quantified and used in the development of an expert system. **Key words:** PSYCHO-BEHAVIORAL PARAMETERS, POSTTHERAPEUTIC FEEDBACK, EXPERT SYSTEMS

SYSTEMIC AND PERIODONTAL INFLAMMATORY BURDEN IN CHILDREN AND TEENAGERS WITH DIABETES, AND CLINICAL CORRELATIONS

SYSTEMIC AND PERIODONTAL INFLAMMATORY BURDEN IN CHILDREN AND TEENAGERS WITH DIABETES, AND CLINICAL CORRELATIONS (Abstract**)** Type 1 diabetes (T1D) remains an eminent global burden, emerging from the impairment of healthy tissues due to an imbalance in the immune system. There is a bidirectional interrelationship between diabetes and periodontal disease (PD), managed through a number of pathways, involving mainly cytokine up- and down regulation. **Objective.** The present study was designed to investigate the possible role of serum and gingival fluid (GCF) levels of interleukin 2 (IL-2) and interferon gamma (IFN-γ) in young patients with systemic alteration in the context of T1D and periodontal injury, and determine its correlation with clinical parameters of the periodontal status. **Material and methods.** Serum and GCF levels of IFN-γ and IL-2 were investigated in 42 patients with T1D with or without periodontal alteration, and 24 systemically healthy controls. Periodontal parameters used in this study were clinical attachment level and papillary bleeding index. GCF was collected using paper strips, while flow cytometric assay was performed to determine the total amount of cytokines. **Results**. The current results revealed that median GCF and serum level of IFN-γ were significantly higher in patients than in systemically healthy controls ($p<0.001$), whereas regarding serum IL-2 levels no significant differences could be noticed ($p>0.05$). Correlation between local and serum cytokines and clinical periodontal parameters revealed significant positive correlation between GCF and serum IFN-γ levels. No association between serum IL-2 levels and clinical parameters of periodontitis was found. **Conclusion**: IFN-γ levels in serum and GCF display a good correlation with clinical parameters and degree of periodontal abuse in young T1D subjects. **Keywords**: TYPE ONE DIABETES, CHILDREN, PERIODONTAL DISEASE

The bidirectional interrelationships between periodontal disease (PD) and type one diabetes (T1D) provide an example of systemic disease predisposing to oral infec-

tion, with subsequent exacerbation of the systemic disease by the oral infection (1).

The inflammatory event that associates periodontal harm is initiated by the accumulation of bacterial plaque and starts in early childhood, reproducing the special significance of the bacterial impact on the host, in a systemic context. Very frequently during children age, the inflammation of the gum remains superficial – at the clinic stage of gingivitis, but there are some cases where the balance between the bacterial assault and the host response is disrupted, leading to destructive action which cause attachment loss, and even the lost of the dental unit.

From the complex interplay between pathogenic bacteria and the host's immune response, a more or less dramatic periodontal injury might result. Several inflammatory mediators, such as IL-2 and IFN-γ have been detected in gingival fluid (GCF) samples in patients with periodontitis, but the results are mostly contradictory due to the lack of homogeneity, collection of sites and protocols for evaluation and analysis.

IL-2 has key roles in significant functions of the immune system primarily via its direct effects on lymphocytes, promoting the differentiation of subsets of immature T cells into regulatory T cells involved in maintaining normal healthy cells in the body (2). Moreover, IFN-γ acts as a positive regulator by selectively prompting Th1 (T helper 1) subset cells differentiation in the coarse of generation of a primary CD4+ (Th1) response.

The present study intended to determine the possible role of Th1-type cells in the disease coarse of T1D children and teenagers with or without periodontal injury, through analysis of serum and GCF levels of IL-2 and IFN-γ, and determine its correlation with different clinical parameters of the periodontal status.

MATERIAL AND METHODS

Subject population and clinical monitoring. Forty-two subjects with diabetes, with (n-20, group 1) or without periodontal changes (n=22, group 2) were recruited from the Metabolic and Nutrition Diseases Department of the University Children Hospital "Sf. Maria" Iasi, and selected based on the following criteria: aged between 6 and 18 years old, diagnosed with T1D. The juvenile individuals with any inflammatory diseases, liver or renal impairment (selected through scan of the serum creatinine levels), periodontal treatment in the previous 6 months prior to the assessment, serious impairment of the dental units or under any medication that could influence the analytes (antibiotics, corticosteroids) were excluded from the study. Twenty-four clinically systemically healthy age matched control group (group 3) were selected among the non-diabetic children and teenagers that followed regular stomatologique cure in the dental unit of the Pediatric Dental Clinic. Informed consent was obtained in all cases, University of Medicine and Pharmacy (Iasi, Romania) Ethics Committee approving the study protocols including the periodontal examination and collection of GCF samples.

Papillary bleeding index (PBI) and clinical attachment loss (CAL) were measured at six sites per tooth (mesiobuccal, buccal, distobuccal, distolingual, mesiolingual and lingual) for all teeth present, by a calibrated examiner.

Gingival crevicular fluid and serum sampling. After isolating the tooth with a cotton roll, supragingival plaque was removed skipping the marginal gingiva. The gingival fluid was collected on paper strips gently placed into the sulcus until mild

resistance was sensed and then left in place for 30 seconds. The volume of each sample was measured using a calibrated device and the reading values were converted to volume (ml) by reference to the standard curve. Following GCF collection, strips were placed in Eppendorf vials and kept at -70°C. Further, the gingival fluid was extracted in 100 ml elution PBS buffer (phosphate saline buffer) by centrifugation at 18.000 g for 5 minutes, at 4°C. From the GCF eluted in PBS, 50 µl specimens were prepared for flow cytometry - FCM analysis.

The degree of metabolic control was considered through glycosylated hemoglobin values (HbA1c) measurements, determined by high performance liquid chromatography; levels of HbA1c $\leq$ 7.5 % were considered for good metabolic control, while poor control was defined as HbA1c > 7.5%, normal values being attributed to HbA1c $\leq$ 6%.

Gingival fluid and serum IL-2 and IFN-γ levels were determined using a high-sensitivity human cytokine multiplex for flow cytometry. Before the assay, GCF samples were eluted using 50 µl of the provided assay buffer, by vortexing for 30 minutes and then centrifuging for 10 minutes at 8000 rpm. The concentrations of the targeted biomarkers in serum and GCF samples were estimated from the standard curve.

Data analysis and statistic evaluation. Periodontal parameters were evaluated from 6 sites per tooth in each subject. Significance of changes in clinical data over time, and serum and CGF cytokine level from the same individual were assessed using the Wilcoxon *t* tests, $p<0.05$ establishing the statistic significance. Interactions between variables were studied using Pearson's correlation, while Mann–Whitney *U* test was used to compare values between groups.

RESULTS

The demographic data including the age of the periodontally affected patients illustrate distributions of more or less severe periodontal impairment: mainly mild affection represented by gingivitis at ages significant lower than previously estimated in the literature (p=0.0048, 95% confidence interval - CI), while form of superficial chronic marginal periodontitis were noticed predominantly in young diabetes subjects close to puberal age. It is to be considered that, very probably, the periodontal injuries recorded around this age interval are modulated by the interdependent metabolic control of the DM disease and hormonal changes registered prior or during puberty (fig. 1).

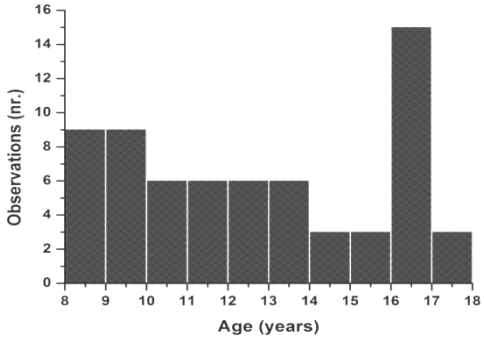

Fig. 1 The histogram of age values in the studied groups

Evaluation of parameters related to distribution, periodontal diagnosis and age that followed the setup of the studied groups, pointed out the highest prevalence of gingivitis (35%), and followed by 20% with chronic superficial marginal periodontitis in the non-diabetes group. Referring to the T1D group, different incidences of periodontal impairment have been recorded in the two subgroups divided by HbA1c levels into: children and adolescents with

good metabolic control (n=10) were diagnosed with bacterial gingivitis in a proportion of 80% (n=8) and 20% aggressive periodontitis (n=2), the poorly controlled T1D, displaying only 60% gingivitis (n=6), chronic superficial marginal periodontitis in 30% (n=3), with 10% aggressive periodontitis (n=1). Therefore, our data support the concept of higher incidence and severity of periodontal breakdown in juvenile individuals with less controlled diabetes at young ages, although there are data that claim no significant correlation between levels of sugar metabolic control and periodontal alter (3).

Correlated to age, systemic disease (T1D) time coarse and metabolic control (reflected by HbA1c levels), analysis of the clinical index that reflect the degree of inflammation on the periodontal area, such as PBI or CAL highlight a significant higher level of the PBI in T1D young subjects (p=0.00, 90%CI) – fig. 2, with significant differences between the mean values of the diabetes duration related to bleeding index, (p=0.0008). PBI correlated well with duration of T1D (r=0.64) but not with the age of the young patients (r=-0.21, p=0.79) in the studied groups.

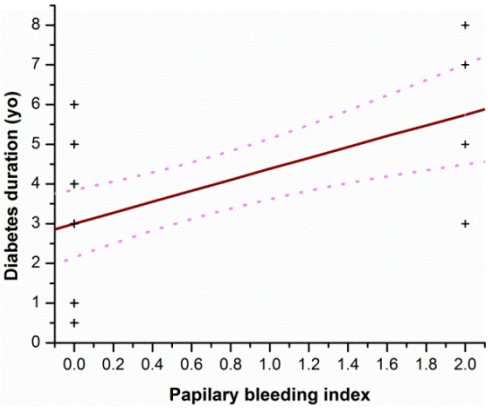

Fig. 2 Regression curve correlating T1D duration *vs.* PBI

The average levels of glycated hemoglobin for our subjects are presented in fig. 3.

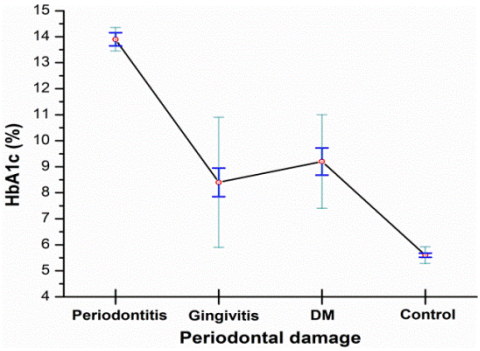

Fig. 3 Mean values of HbA1c *vs.* studied groups

These values have been correlated to clinical index of periodontal modification and revealed that moderate or poor controlled T1D associates higher levels of the bleeding index, the levels of glycated hemoglobin registering significant upper values in groups of diabetic patients attended by periodontal injury, compared to control group (fig. 4). Positive relationships were found between HbA1c and clinical parameters such as attachment loss, correlation coefficient being rather high (r=0,76), with a p value close to null and 95% confidence interval (fig. 5).

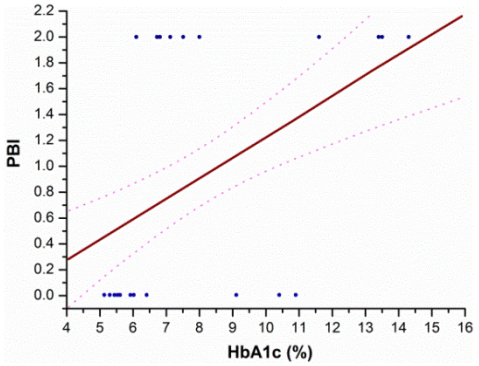

Fig. 4. Regression curve correlating PBI to HbA1c

When the level of periodontal impairment (reflected in clinical index such as PBI and CAL) was correlated with the onset age of the systemic alteration (T1D), a significant positive correlation was seen among all the groups (p=0.03684, 95%CI).

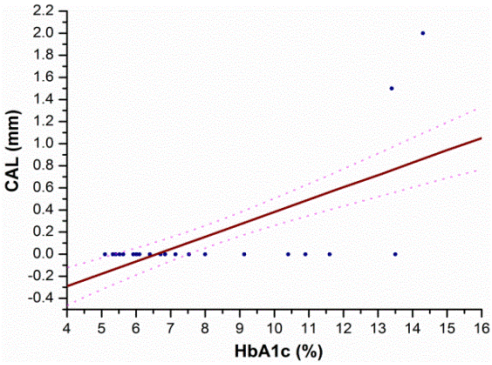

Fig. 5. Regression curve in correlation CAL vs. HbA1c

Slight and moderate elevated levels of serum IFN-γ in T1D subjects compared to control, whereas significant higher GCF amounts within group one were noticed. Both serum and gingival fluid IL-2 levels are very small in patients in group 1, suggesting the existence of a local factor that blocks secretion especially in diabetic patients with periodontal alteration (fig. 6,7).

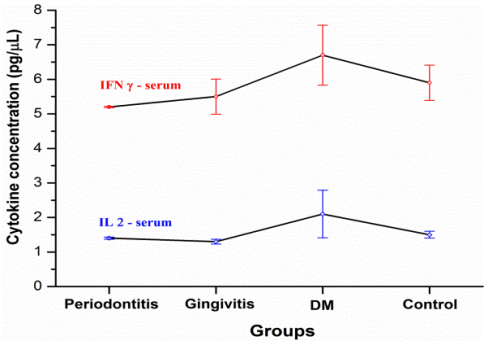

Fig. 6. Mean values of serum IL-2 and IFN-γ in the studied groups

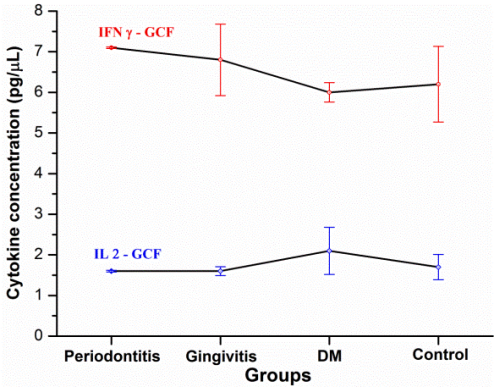

Fig. 7. Mean values of gingival fluid IL-2 and IFN-γ in the studied groups

DISCUSSION

The pro-inflammatory cytokines such as interferon gamma, Il-1 beta, IL-2 as well as eicosanoids like prostaglandin E2, reach elevated tissue levels during PD, the periodontium serving therefore as a pool for spillover of these mediators that can determine extension of systemic outcomes (4,5). More recently, some clinical and laboratory studies have provided irrefutable evidence that periodontal breakdown may affect the host's susceptibility to systemic disease (6).

IFN-γ and IL-2 are cytokines released by the Th1 subset of CD4+ T cells. Moreover, due to the consistent pro-inflammatory events mediated through IFN-γ, there is a significant activity attributed to Th1-type cells for the elicited periodontal injury (7). To date, the literature concerning the behavior of these two mediators is conflicting; therefore, despite that most of the researchers claim the association of elevated local IL-2 and IFN-γ levels with progressing periodontal injury during chronic periodontal harm (7), with recent investigations reporting statistically important decreases in gingival fluid IFN-γ and IL-2 values consequently mechanical periodontal treatment (8), a tendency in augmenting local IFN-γ

levels after periodontal cure have been also reported (9). There is mount literature data that claim cytokines as key factors mediating inflammatory events (10, 11).

Our results recorded significant correlations of the clinical periodontal status, both with the biological parameters of the diabetic disease and also with the host immune-inflammatory reaction. Previous studies revealed that serum IL-2 levels were diminished in patients with chronic periodontal injury as compared to controls (12), while other study pointed out that serum IL-2 recorded higher values in adult individuals with chronic periodontitis compared to control group, although no statistically significance could be noticed (13).

T1D subjects presented significant PBI and CAL levels when compared to control group, in agreement with a number of studies (14, 15), the significant positive correlation registered between the onset of the diabetic disorder and clinical periodontal index pointing out that biochemical changes occurring at systemic level during the diabetic disease occur simultaneously at the local level. Hence, our data sustain the concept that the duration of T1D disease and metabolic control of the systemic impairment could act as contributing elements in convicting DM as risk factor within PD. Moreover, as a future perspective, GCF can be valued as a non-invasive diagnostic fluid over blood analysis in malady diagnosis.

Only IFN-γ registered moderate augmented serum levels within T1D children and adolescents compared to control, whereas significant higher amounts of GCF interferon gamma have been recorded in group one. Measurements of IFN-γ in GCF may be regarded as a valuable noninvasive and rapid approach for monitoring periodontal disease status.

CONCLUSIONS

In our study, serum and gingival fluid IFN-γ correlated well with clinical parameters and degree of periodontal abuse. Our data support the idea that gingival fluid IFN-γ levels could be a suggestive parameter to distinguish the patients with risk of diabetic disease expansion toward periodontal inflammatory or destructive episodes.

AKNOWLEDGMENTS

This study was supported by Program of Excellency in doctoral and post-doctoral multidisciplinary chronic disease research, POSDRU grant 159/1.5/S/133377 from the University of Medicine and Pharmacy "Grigore T. Popa" Iasi, Romania, project cofinanced from European Society Foundation by Operational Sectorial Programme of Human Resources Development 2007-2013.

EFFECTS OF *ZINGIBER OFFICINALE* ROSCOE FRESH EXTRACT ON AMELANOTIC MELANOMA AND NORMAL SKIN FIBROBLASTS (Abstract): *Zingiber officinale* Roscoe is a very important medicinal plant, with a long history of therapeutic uses, especially in oriental traditional medicine. **Aim**: To investigate the cytotoxicity of a fresh ginger extract on some skin tumor cells compared to normal cells. **Material and methods**: C32 amelanotic melanoma cell line and CCD human skin fibroblasts were used. The fresh extract obtained by crushing ginger rhizome was examined for phenolic content. The *in vitro* cytotoxicity was examined using phase contrast microscopy and MTT assay for the concentrations of 2 and 4 mg% total phenols. **Results**: Both concentrations used for treatment induced no changes in normal the morphology and viability of fibroblasts compared to control cells. Amelanotic melanoma cells displayed profound changes in cell morphology such as cell shrinkage, rounding up and membrane blebbing and a decrease in cell viability in a dose-dependent manner. **Conclusions**: Fresh ginger extract induced no changes in normal skin fibroblast viability, but caused profound cytotoxic effects on amelanotic melanoma. These results could encourage further studies regarding the intimate mechanisms of the antitumor action displayed by the fresh ginger extract. **Keywords**: *ZINGIBER OFFICINALE* ROSCOE, NORMAL SKIN FIBROBLASTS, AMELANOTIC MELANOMA, CELL VIABILITY

Numerous scientific studies linked the biologically active compounds extracted from plants with the antitumor activities against different types of cancer (1).

Ginger (*Zingiber officinale* Roscoe) is a perennial plant used since ancient times for spicing food and beverages, but also in treating different types of ailments, especially in oriental traditional medicine. Digestive disorders, inflammation, cold and hypertension are among the most known diseases against which ginger extracts can be used. The phenolic compounds present in it (especially gingerols and shogaols) have been proposed as important antioxidants with notable anticancer and antimutagenic effects (2). Promising results were obtained after *in vitro* and *in vivo* studies on lymphoma, ovary, gastrointestinal, skin, breast and lung cancers, promyelocytic leukemia, oral squamous carcinoma and others. In these cases, the anticancer

action consists in the inhibition of angiogenesis and apoptosis triggering through caspase-3-dependent mechanisms, down-regulation of anti-apoptotic Bcl-2 protein, up-regulation of pro-apoptotic Bax protein and inhibition of DNA synthesis (3).

Amelanotic melanoma is a type of skin melanoma generally characterized by lack of pigmentation and is associated with very poor prognosis when diagnosed in late stages (4). Promising effects were obtained after exposure to plant essential oils (5) and extracts of *Curcuma longa*, *Bouea burmanica* and *Iris pseudopumila* (6, 7).

The aim of this study was to investigate the cytotoxicity of a fresh ginger extract used in two different total phenols concentrations on some amelanotic melanoma cells in comparison with normal skin fibroblasts.

MATERIAL AND METHODS

Biological material and reagents. The human amelanotic melanoma cells (C32 cell line) and normal human fibroblasts (CCD cell line) were purchased from American Type Culture Collection (ATCC®CRL-1585™ and ATCC®CRL-1459™).

Minimum essential medium (MEM), Dulbecco's Modified Eagle's Medium (DMEM), fetal bovine serum (FBS), antibiotic mix and phosphate buffer saline (PBS) were purchased from Gibco-Invitrogen (Grand Island, NY, USA). Trypsin, ethylenediaminetetraacetic acid (EDTA), 3-(4,5-dimethyl-thiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and absolute isopropyl alcohol were purchased from Sigma-Aldrich (St. Louis, MO, USA). All reagents were of analytical grade.

Plant material. *Zingiber officinale* Roscoe rhizome was purchased from the local market and the species was taxonomically identified by specialists from "Alexandru Ioan Cuza" University of Iasi, Romania, Faculty of Biology. A voucher herbarium specimen is deposited in the Laboratory of Biochemistry, Faculty of Biology, "Alexandru Ioan Cuza" University of Iasi, Romania.

Preparation of Zingiber officinale* Roscoe *fresh extract. Ginger rhizome was properly washed with distilled water and the external layer was detached. The material was then crushed using a glass laboratory blender and centrifuged for 30 minutes at 10 000 x g and 4°C. The supernatant was filtered twice using 0.22 □m sterile filters and used for polyphenol content determination and cell viability tests.

Cell culture. The C32 cells were first seeded in culture flasks at a density of 6 x 10^4 cells/mL and grown in *Minimum Essential Medium* (MEM) supplemented with 10% FBS, penicillin (100 U/mL) and streptomycin (100 µg/mL).

The CCD cells, seeded at a density of 6 x 10^4 cells/mL were grown in DMEM supplemented with 10% fetal bovine serum and an antibiotic mix (100 U/mL penicillin, 10 µg/mL streptomycin and 25 µg/mL amphotericin).

The cell lines were maintained in a humidified atmosphere of 5% CO_2 at 37°C. The culture medium was changed every 2 days until 80% confluence.

Total phenolic content. The total phenolic content was determined by Folin-Ciocâlteu method, modified by Singleton *et al*., 1999 (8). The method consisted in the reduction of Folin-Ciocalteu reagent in alkaline medium. The intensity of the blue compound obtained was proportional with the phenolic content and was determined using a Perkin Elmer Lambda 25 spectrophotometer. The concentration was expressed as mg of gallic acid equivalents (GAE) per 100 ml extract (9, 10).

Cell viability assay. Cell viability was

measured by the MTT [3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide] assay (11). The C32 and CCD cells were seeded in 12 well plates and cultivated until they reached 80% confluence. Then, they were synchronized in the same phase of cell cycle for 18 hours. A treatment with fresh ginger extract containing 2 and 4 mg% GAE was administered. After 24 hours of exposure, the cells were observed by phase contrast microscopy on an inverted Olympus IX71 microscope in order to establish the morphological changes. The cells were subsequently incubated with 1 mg/mL MTT for 3 h at 37°C. The medium was then removed and 100 µL of absolute isopropyl alcohol were added to each well for the solubilization of formazan crystals. The optical density was read at 595 nm using a TECAN GENios plate reader and was directly correlated with the number of viable cells.

Statistics. All determinations were carried out in triplicate. The results were analyzed using Student t test and Microsoft Excel software. The values were expressed as means ± standard deviation and represented graphically as percentage of control. $p<0.05$ values were considered significant (*), $p<0.01$ distinctly significant (**) and $p<0.001$ very significant (***).

RESULTS AND DISCUSSION

Total phenolic content. The total phenolic content in ginger fresh extract was 203.55 ± 6.27 mg GAE/100 ml. The extract was then diluted in cell culture medium in order to obtain a concentration of 2 and 4 mg% GAE for the treatment of CCD and C32 cells.

Cell morphology. After the 24 hour treatment with 2 and 4 mg% GAE, the treated normal human skin fibroblasts, amelanotic melanoma cells and control cells were observed by phase contrast microscopy. Untreated CCD cells are presented in figure 1a. Figures 1b and 1c show the human fibroblasts after exposure to fresh ginger extract. C32 cells (control and treated ones) can be seen in figure 2.

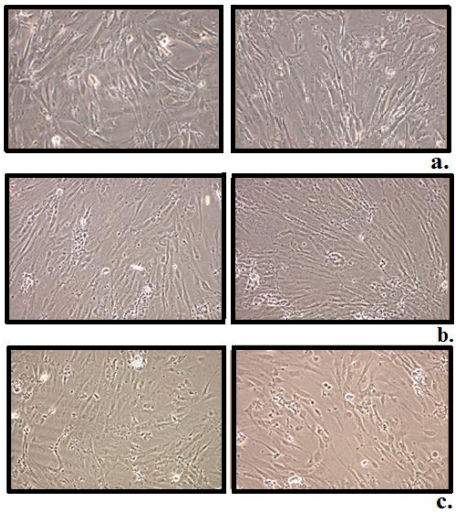

Fig. 1. Fields of control CCD cells (a) and CCD cells treated with 2 mg% GAE (b) and 4 mg% GAE (c)

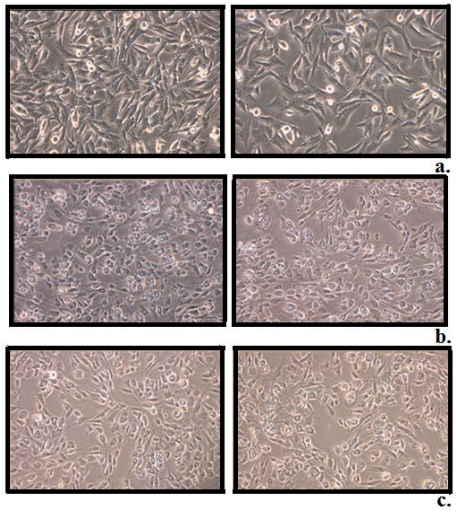

Fig. 2. Fields of untreated C32 cells (a) and C32 cells treated with 2 mg% GAE (b) and 4 mg% GAE (c)

Cell viability. Figure 3 shows the results obtained after MTT cytotoxicity test on normal and tumor cells. Both phenolic concentrations used for treatment induced no changes in the viability of normal fibroblasts. In the case of C32 cell line, with the first concentration (2 mg% GAE), cell viability decreased by almost 30% compared to control cells. The concentration of 4 mg% GAE induced a higher decrease in cells viability, by about 41% compared to controls.

	CCD cell line	C32 cell line
C	100	100
2 mg GAE%	100,048	70,677
4 mg GAE%	100,414	58,581

Fig. 3. Relative CCD and C32 cell viability after 24 hours of treatment

Previous studies showed an important inhibitory activity induced by some ginger varieties, also revealed by MTT assay on some human breast cancer cell lines (MCF-7 and MDA-MB-231) (12). The 6-shogaol, one of the main biologically active compounds of ginger, was reported as a significant dose-dependent inhibitor of HeLa cells proliferation (13).

In order to establish the efficacy of fresh ginger extract in the induction of cell death, we first observed the amelanotic melanoma cells by phase contrast microscopy. The effect was compared to the one obtained in normal skin fibroblasts.

Treated CCD cells shown in figure 1 revealed no significant changes in cell morphology. The cells remained oblong and no detachment from the growing surface was observed. The higher level of viable normal cells was confirmed by MTT test.

On the other hand, fresh ginger extract was able to induce a decrease in vitality of C32 cells after 24 hours of incubation (fig. 2). The melanoma cells treated with fresh extract containing 2 and 4 mg% phenolic compounds displayed evident morphological changes typical for cells undergoing cell death, such as: cell shrinkage, rounding up and membrane blebbing. Furthermore, the results obtained by MTT assay (fig. 3) revealed a dose-dependent decrease in cell viability after exposure to fresh plant extract. It is possible that at polyphenols con-

centrations higher than those used by us tumor cell viability to decrease even more.

CONCLUSIONS

Our comparative analysis on the effects induced by a fresh ginger extract on C32 amelanotic melanoma cell line and CCD normal human fibroblasts revealed a down regulation of tumor cell viability in a dose-dependent manner and no change in normal cell viability at the same treatment concentrations. Further studies are needed in order to understand the intimate mechanisms of inhibition of melanoma development due to the fact that the extract used by us seems to be effective in this type of cancer.

ANALYSE OF SOCKET-PROSTHESIS-BLUNT COMPLEX FOR LOWER LIMB AMPUTEE USING OBJECTIVE MEASURE OF PATIENT'S GAIT CYCLE (Abstract): The prosthetic application is a highly complex process. Modeling and simulation of biomechanics processes in orthopedics is a certainly field of interest in current medical research .Optimization of socket in order to improve the quality of patient's life is a major objective in prosthetic rehabilitation. A variety of numerical methods for prosthetic application have been developed and studied. **Material and methods**: An objective method is proposed to evaluate the performance of a prosthetic patient according to surface pressure map over the residual limb.The friction coefficient due to various liners used in transtibial and transfemoral prosthesis is taken into account also. **Results**: Creation of a bio-based modeling and mathematical simulation allows the design, construction and optimization of contact between the prosthesis cup and lack of functionality of the patient amputated considering the data collected and processed in real time and non-invasively. The von Mises stress distribution in muscle flap tissue at the bone ends shows a larger region subjected to elevated von Mises stresses in the muscle tissue underlying longer truncated bones. **Conclusions:** Finite element method was used to conduct a stress analysis and show the force distribution along the device. The results contribute to a better understanding the design of an optimized prosthesis that increase the patient's performance along with a god choice of liner, made by an appropriate material that fit better to a particular blunt. The study of prosthetic application is an exciting and important topic in research and will profit considerably from theoretical input. Interpret these results to be a permanent collaboration between math's and medical orthopedics. **Keywords:** PROSTHETIC, SOCKET, BLUNT, SOLID WORKS, NUMERICAL MODELING.

Lower limbs prosthetic have many particular features that are taken into account in design and adjustment of prosthesis to make less discomfort as possible for patient. There are many papers related usage of finite-element method applied to transfemoral amputation but there are relatively less papers related to trans-tibial amputation.

The liner used as interface between skin and socket alleviates the satisfaction and patient's comfort improving considerably the quality of life. The material of liner and consequently the coefficient of friction

between skin and liner has a major influence in performance of prosthetic amputee. The dynamic level of pressure between stump and prosthetic socket has a very high influence on patient's comfort (1). Two new materials (Dermo and the Seal-In X5 liner) are tested in (1). The points of measurement for interface pressure were chosen according to information from literature were the most probable location of the pressure peaks: anterior, posterior, medial and lateral regions. The patient' satisfaction was measured qualitatively using a questioner (Prosthetic Evaluation Questionnaire) and the conclusion was that Dermo liner provide more comfort that the other liner, Sean in (1).

An investigation related to interface stress between stump and trans-tibial prosthetic socket using 3D nonlinear finite element based on geometry of limb was done in (2). Automated surface-to-surface contact available in ABAQUS was used to model boundaries conditions (friction/slip)(2). The effect of load during gait cycle internal tissue of residual limb was studied in (3,4). The authors proved that the internal stress in are dependent on walking terrain, the more uneven or difficult is the terrain (e.g. stairs), the higher are the peaks of internal mechanical stress in the muscle flaps (4). Turning plays an important role in all the daily activities of patients with amputation of lower limb. In (5), compensatory strategy mechanisms developed by transtibial amputee were studied in comparison with non-amputee. The authors studied the evolution of main forces involved in turning: radial ground reaction and anterior–posterior forces (5). Modelling by finite element method (FEM) is often used in analysis of prosthetics for lower limb. FEM is used in (6) in donning procedure using patient-specific geometry given by CT and laser scan data. In distal-end socket type, the friction role is analyzed in (7).

Most of the studies in prosthetic application use the elastic, homogenous and isotropic models for bones soft tissues, flap muscles, fat, liner, and socket. Based on theory of large elastic deformation (8), other approaches more realistic studies that tackle with hyperelastic tissues are published by different authors (6,7,9). The models are more realistic ones, and in condition that constants for most common materials used in prosthetic models are available in publication we will use in this paper the hyperelastic Mooney-Rivlin model (7).

MATERIALS AND METHODS

We propose to use a fused adapted gait deviation index (faGDI) as objective measure of performance for lower limb amputee for pairs liner-socket materials.Gait deviation index (GDI) is proposed to be used as index of gait pathology for non-amputee persons in very recent papers (10,11). About our best knowledge, only one paper that tackle with lower limb amputee using GDI is published until now.There are few proposals for gait deviation index: Gillette Gait Index (GGI), Gillette Functional Assessment Questionnaire Walking Scale (GFAQW), and topographic classifications (diagnosis of Cerebral Palsy -CP). GDI include a balanced analysis of univariate parameters, SVD (Singular Value Decompositions) and singular values for each parameter are identified (10).The moments and joint power in different location are correlates with the body mass of subject.

Instead to use the GDI for pathology identification, we propose to use infor-

mation given by pressure sensors in order to evaluate the faGDI as objective measure for quality of prosthesis. The moment $M_{sensorx}$ is used for rotation (turning gait).

$$G_f = \begin{bmatrix} F_{sensor1}, F_{sensor2}, F_{sensor3}, \\ F_{sensor4}, F_{sensor5}, F_{sensor6} \\ M_{sensorx} \end{bmatrix}$$

Fig. 1. Six pressure sensors mounted on stump

Data were collected from two amputee (fig. 1) with set of 32 repetition of cycle (8 cycles for normal walking, 8 cycles for up the stairs, 8 cycles for down the stairs and 8 cycles normal walking with two rotation on each cycle. The vectors collected from each subject were concatenated in a faGDI matrix:

$$G_f = \begin{bmatrix} \begin{pmatrix} g_{1`}^1 \\ g_2^1 \\ \vdots \\ g_{32}^1 \end{pmatrix} \begin{pmatrix} g_{1`}^2 \\ g_2^2 \\ \vdots \\ g_{32}^2 \end{pmatrix} \cdots \begin{pmatrix} g_{1`}^m \\ g_2^m \\ \vdots \\ g_{32}^m \end{pmatrix} \end{bmatrix}$$

Practically, faGDI is a scaled measure of distance between a patient' gait ant the other from the same group.

RESULTS AND DISCUSSION

In the first stage we considered the materials homogenous. The material properties are taken from literature (13) and are summarized in tab. 1. The materials used in the analysis, with the characteristic parameters, are listed in a library of materials, from where are accessed.

TABLE I

Material Properties for homogeneous FE model

	Young's Modulus	**Poison's ratio**
Bone	15 GPa	0.3
Soft tissue	200 KPa	0.45
Socket	15 GPa	0.3
Liner	0.38 MPa	0.49

All soft tissues were assumed to be hyperelastic, homogeneous, and isotropic, and were modeled using the Generalized Mooney-Rivlin Solid strain energy function (7):

$$E = C_{10}(I_1 - 3) + C_{11}(I_1 - 3)(I_2 - 3) + D_1(J - 1)^2$$

The constants which depend on material are taken from literature (7). It is clear that on wearing trans-femoral prosthesis higher strain occurs at the brim of socket. Equivalent Von-Mises stresses acting on different parts of above knee prosthesis is as shown in fig. 2-4. The von Mises stress distribution in muscle flap tissue at the bone ends shows a larger region subjected to elevated von Mises stresses in the muscle tissue underlying longer truncated bones

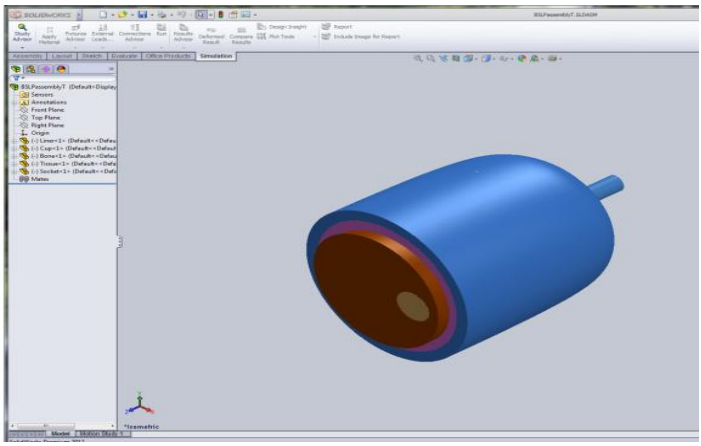

Fig. 2. SolidWorks approximation for assembly femur-stump-liner-socket.

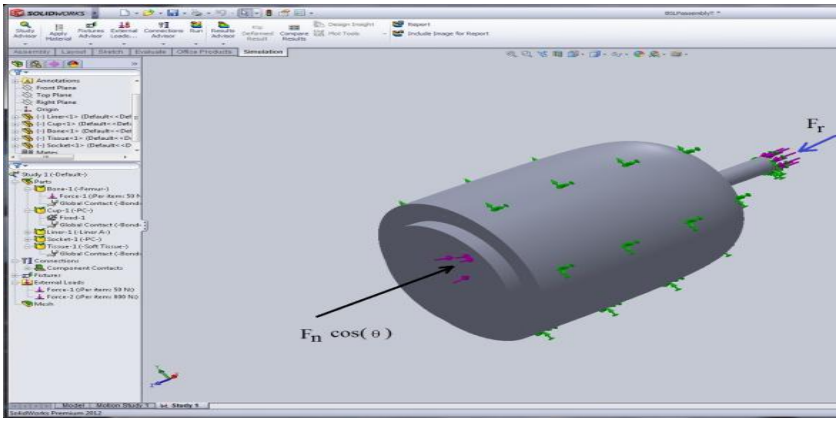

Fig. 3. Force applied to assembly femur-stump-liner-socket during gait cycle

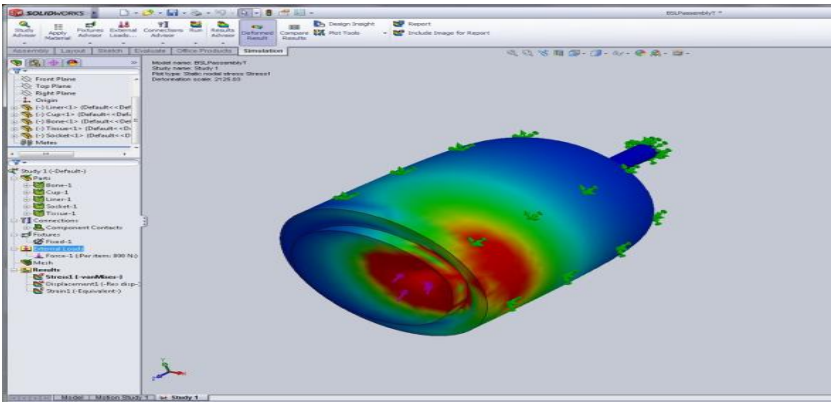

Fig. 4. Von Misses force in internal tissues for assembly femur-stump-liner-socket during gait cycle. The von Mises strain wasfound maximum at the bottom line of the socket

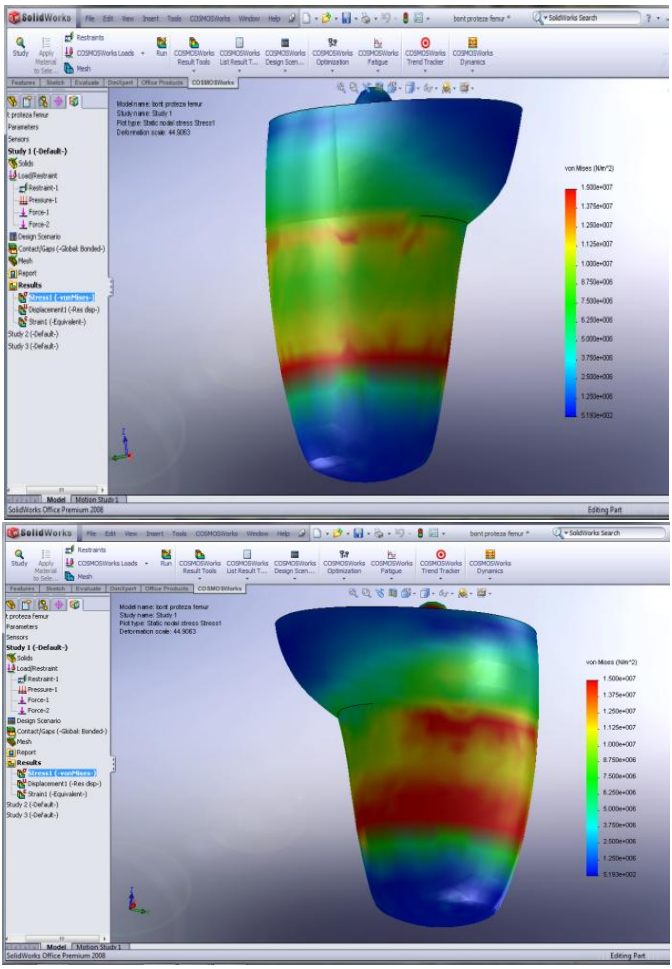

Fig.5. Von- Mises result, at the level of internal side of the thigh and Von- Mises result at the level of external side of the thigh.

CONCLUSIONS

The use of Solid Works in this article illustrates the important role of informatics in research in biomechanical modeling .An objective method is proposed to evaluate the performance of a prosthetic patient according to surface pressure map over the residual limb is proposed in this paper. Two liners are investigated during simulations using FEM. The distal end boundary conditions are marked by using large deformations permitted by SolidWorks Premium 2012 and kinetic records. The experimental results showed an average of faGDI ≈ 121,47 for Dermo liner and faGDI ≈ 105,62 for Sean-in. Based on this results, we can conclude that the combination polyurethane socket-Dermo liner is more performant that polyurethane socket- Sean-in liner. The design solution obtained from the results can be used as a reference to choose material for fabrication of socket in developing countries like Romania, depending on the cost and availability.

EFFECTS OF TWO SEROTONINERGIC AGENTS ON THE BEHAVIORAL MANIFESTATIONS IN RATS (Abstract) **Aim:** To investigate the effects of two serotonin receptor antagonists on spontaneous behavior in rats. **Material and method:** The experiment was carried out on white male Wistar rats (150-200g) divided into 3 groups of 6 animals each, treated intraperitoneally with the same volume of solution as follows: Group I (Control): saline solution 0.1ml/10g weight; Group II **(**SB-269970**):** SB-269970 1mg/kbw; Group III (NAN-190): NAN-190 1mg/kbw. The effects of serotonin receptor antagonists on the spontaneous psychomotor skills of rats were tested in Actimeter LE-8811 (PanLab). The data were presented as mean +/- standard deviation and significance was tested by SPSS Statistics for Windows version 17.0 and ANOVA method. The experimental protocol was implemented according to the guidelines for handling and use of experimental animals of the Research Ethics Committee of the Iasi "Grigore T. Popa" University and ethical standards of the European Community. **Results:** The 5HT1 serotonin receptor antagonist NAN-190 determined a statistically significant reduction ($p<0.01$) in both horizontal and vertical movements as compared with the control group, whereas the 5HT7 serotonin receptor antagonist SB269970 had no influence on rat behavioral manifestations. **Conclusions:** In our experimental conditions 1 mg/kbw NAN-190 decreased the total escape attempts, corresponding to a significant diminution of exploratory and self-maintenance spontaneous behavior in this experimental animal model. These manifestations may be correlated with the anxiolytic effect of 5HT1 serotonin receptor antagonist NAN-190 in rats. The administration of 5HT7 serotonin receptor antagonist SB-269970 did not alter the spontaneous activity in this behavioral experimental model in rats. **Keywords:** NAN-190, SB-269970, BEHAVIOR, RATS.

The monoamine neurotransmitter 5-hydroxytryptamine (5-HT, serotonin) has been implicated in different types of behavior, such as emotional, motor, cognitive processes. It is also implicated in the mediation of autonomic neural processes, neuroendocrine functions, circadian rhythm, and feeding behavior (1). Serotonin has important physiological effects being interconnected with many mediators that participate in the hypothalamic control of pituitary secretion, predominantly in the modulation

of adrenocorticotropin, growth hormone, and prolactin secretion (1, 2). The main source of 5-HT release in the brain is represented by the neurons of raphe nuclei (1).

Various disturbances in central tryptaminergic pathways are suggested to be linked with the manifestation of the most important behavioral disorders. This fact may explain the effectiveness of serotonin receptor antagonists in different behavioral diseases (3).

Serotonin has an intense influence on mood. High levels of serotonin lead to a positive disposition and coping more effectively with daily stressful situations. On the other hand low serotonin levels are responsible for the development of different degrees of depression (4).

5-HT has an inhibitory effect on loco motor activity, as a result of a complex action mediated through modulation of the serotoninergic system, but this activity is interconnected with both dopaminergic and glutamatergic pathways (5).

The perturbation of serotoninergic system has been shown to influence a variety of behavioral disorders, including obsessive compulsive disorder, panic disorder, body dysmorphic disorder, phobias, posttraumatic stress disorder, anorexia, bulimia, attention-deficit hyperactivity disorder, and insomnia, and thus a first therapeutic possibility of defense consists of drugs that influence serotonin levels in the brain (3, 6).

Literature data show that active substances affecting serotonergic neurons and their receptors are used to treat diseases such as depression, anxiety disorders, and schizophrenia (2, 4).

NAN-190 is a (1-(2-methoxyphenyl)-4-[4-(2-phtalimido)butyl]piperazine) derivative, with a selective antagonistic activity on $5HT_{1A}$ serotonin receptor subtype. It has been demonstrated that this pharmacologically active substance also has an adrenergic stimulation activity and a presynaptic $5HT_{1A}$ serotonin receptor agonistic effect (7, 8, 9).

(R)-3-[2-[2-(4-Methylpiperidin-1-yl) ethyl] pyrrolidine-1-sulfonyl]phenol hydrochloride compound, SB269970 is a 5HT7 serotonin receptor antagonist and also an alpha 2 adrenergic receptor blocker (10, 11, 12).

This research is part of a large study aimed to investigate the effects of various serotoninergic and dopaminergic agents on spontaneous motor activity, behavior, and cognitive processes in laboratory animals (13, 14).

MATERIAL AND METHODS

Male white Wistar rats (150–200g) were used in the study. The animals were housed in plastic cages for 10 days prior to initiation of experiments under standard conditions of room temperature (23 ± 1°C) and 12:12 h light/dark cycle (light on at 07:00).

Water was available *ad libitum* and animals were maintained at 85% of their free feeding weight by controlling the amount of their single daily meal 45 minutes after the experimental session. Before the experiment, rats were placed on a raised wire mesh, under a clear plastic box and allowed 2 hours to acclimate to the testing room.

The animals were divided into 3 groups of 6 rats each, and treated intraperitoneally with the same volume of solution as follows: Group I (Control) saline solution 0.1ml/10g weight; Group II (NAN-190) NAN-190 1mg/kbw; Group III (SB-269970) SB-269970 1mg/kbw.

Actimeter test was performed to determine the effect of serotonin receptor antagonists on spontaneous loco motor activity and exploration in rats. This apparatus consists of three transparent cages each with eight infrared lights located in a frame

around the cage and connected to silent electronic counters. The device is composed by a two dimensional (X and Y axes) square frame, a frame support, and a control unit. Animal activity is measured by light beams connected to a photoelectric cell. The number of light beam interruptions due to the animal movements inside the cage was automatically recorded. The system is completely modular: each frame may be used for evaluation of general activity, locomotor, stereotypic movements, rearing or exploration (15). The frames are connected directly through SeDaCom computer Software, which allows easy exportation of data in a format compatible with Excel program for Windows.

The animals were kept in the test room for 1 hour before the test for habituation. After the vehicle or tested substances were injected, the animals were placed on the cage device and each movement produced a signal caused due to variation in inductance and capacity of the apparatus resonance circuit. These signals were automatically converted to numbers.

Horizontal or vertical activity is defined as the total number of beam interruptions over a certain period. In this experiment the total number of horizontal cage crossing, vertical and stereotypic movements were recorded automatically over a period of eight minutes (16).

Each animal in the study groups was subjected to 2 minute successive tests, the animal being placed on the work surface and repeatedly replaced in its cage.

The values were recorded electronically and displayed according to prior programming of an electronic system for data processing.

Data for each measure were evaluated separately by *analysis of variance* for repeated determinations. Results were expressed as *arithmetic mean* ± SD and represented graphically.The analyses of the effect of serotonin receptor antagonist on rat behavior in the Actimeter test were conducted by *SPSS version 17.0* for Windows and by 1-way analysis of variance (ANOVA). P-values less than 0.05 were considered statistically significant compared to controls.

Experimental protocol was conducted according to the guidelines for handling and use of experimental animals of the Research Ethics Committee of the Iasi ”Grigore T. Popa”University,in compliance with the ethical standards of the European Community.

Each animal was used only once and the duration of the experiments was kept as short as possible. For ethical reasons, all animals were sacrificed at the end of the experiment (17, 18).

RESULTS AND DISCUSSION

Using the behavioral experimental model, we obtained four types of information regarding the animal spontaneous motor activity: total, horizontal, vertical and stereotypic movements.

The number of total movements represents a feature that reflects the overall intensity of animal behavior over a period of time and is also a good way of corroboration and validation of data biological significance (15).

Actimeter test exhibited sensitivity for detecting changes in total movement counts, as was seen after NAN-190 and SB-269970 treatment.

The change in spontaneous loco motor activity of laboratory animals (as assessed by the number of infrared beam breaks along horizontal or vertical planes) represents a versatile preclinical analysis procedure regarding the central neurobehavioral

effects of tested substances. Spontaneous loco motor activity assessment may be a suitable method for the screening and comparison of the effects of different pharmacologically active substances (19, 20).

The administration of NAN-190 (1 mmol/kbw) resulted in a statistically significant reduction of total movement (147.17±4.36), ($p<0.05$) as compared to the control group (179.67±7.03).

In the same experimental conditions, intraperitoneal injection of SB-269970 1mg/kbw was not associated with a significant change in rat total movements (176.67±8.91) compared to saline solution group (fig. 1).

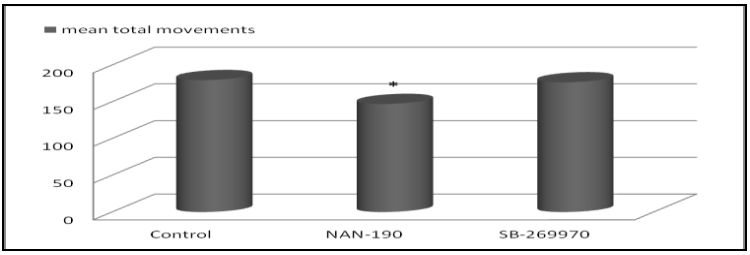

Fig 1. The number of total movements induced by NAN-190 and SB-269970 in Actimeter test. Each point is the mean ± SEM of latency time (seconds) for six rats. *p<0.05, **p<0.01 *vs.* control.

The number of movements in the horizontal plane provides data on the general behavior exploration of the environment, but also about the self-maintenance of animal personal hygiene (paw-licking behavior, hair combing and nose cleaning, by and large, self-directed, possibly recuperative, behaviors – auto-grooming) (16, 19).

The Actimeter test offer the possibility to detect changes in horizontal activity counts, as was observed after NAN-190 and SB-269970 treatment.

Intraperitoneal administration of NAN-190 (1 mmol/kbw) produced a reduction of horizontal movements (131.83±5.19), statistically significant ($p<0.05$), comparing with control group (160.17±8.64) in this behavioral manifestations in rats.

Using SB-269970 (1mg/kbw) we did not obtained a significant modification of animals horizontal movements (157.50± 8.55) compared to control group (fig. 2).

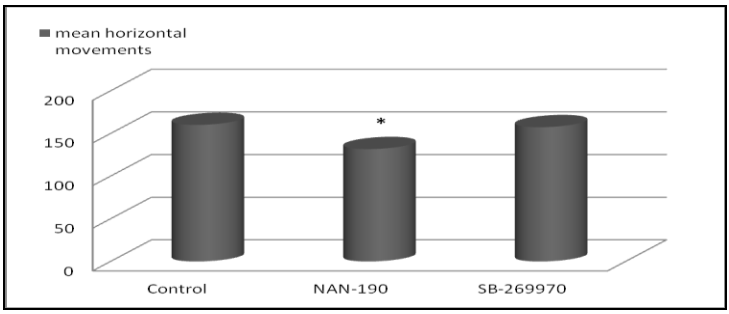

Fig 2. The number of horizontal movements induced by NAN-190 and SB-269970, in Actimeter test. Each point is the mean ± SEM of latency time (seconds) for six rats. *p<0.05, **p<0.01 *vs.* control.

The vertical movements (rearing behavior) reflect that animals are exploring, trying to climb on the transparent walls of registration cage, and are suggestive for attempt behavior, a correspondent for the indirect fear and anxiety states (15, 20).

The Actimeter method gave us the opportunity to detect changes in horizontal activity counts after NAN-190 and SB-269970 administration. NAN-190 produced a statistically significant decrease in vertical movements (15.33±3.33), compared to control group (19.5±1.87) in Actimeter test in rats.

The administration of SB-269970 did not statistically influence the rat vertical movements (19.17±1.94) in this experimental behavioral model (fig. 3).

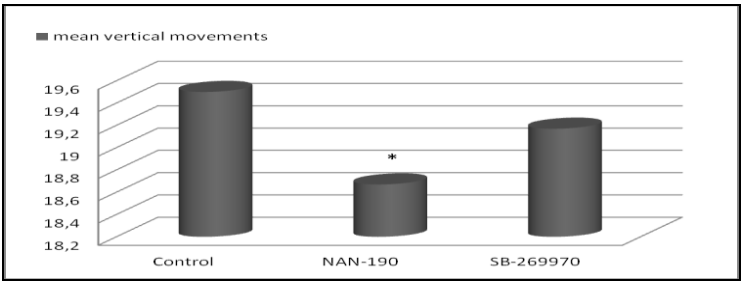

Fig 3. The number of vertical movements induced by NAN-190 and SB-269970, in Actimeter test. Each point is the mean ± SEM of latency time (seconds) for six rats. *p<0.05, **p<0.01 *vs.* control.

CONCLUSIONS

Using a behavioral model to evaluate the exploratory activity and motor coordination in rats, we determined that in our experimental conditions the intraperitoneal administration of 1 mg/kbw NAN-190 resulted in a statistically significant reduction of movements in horizontal and total movement counts compared to controls.

These results reflect the decrease in the number of escape attempts and a significant diminution of exploratory and self-maintenance spontaneous behavior. Corroboration of the two observed changes reflects a type of behavior that in humans corresponds to a decrease of anxiety.

Our results show that in the used mouse model of behavioral manifestations, magnesium soft matter vesicles carrier diminished both global motor behavior and the number of escape attempts, which could correspond somehow to general behavioral inhibition or sedation in humans.

Extrapolation of these results is however difficult, because of the huge differences in behavior, cognitive function, and motor coordination skills between laboratory animal and humans.

SPECTROPHOTOMETRIC METHODS FOR ESTIMATION OF BISOPROLOL FUMARATE IN TABLETS (Abstract): Bisoprolol fumarate is prescribed for the treatment of hypertension and angina pectoris. **Aim:** The purpose of this study was to develop a simple, sensitive, accurate, and reproducible method for estimation of bisoprolol fumarate in tablets. **Material and methods:** The proposed method was based on a yellow colored complex formed with tropaeolin 00, extractable in dichloromethane with maximum absorbance at 412 nm. The method was validated statistically. **Results:** The linearity domain was observed in the concentration of 5-30 µg/ml. The recovery studies confirmed the accuracy of the proposed method. **Conclusions:** The proposed method can be applied for the routine analysis of bisoprolol from formulations. **Keywords:** BISOPROLOL FUMARATE, SPECTROPHOTOMETRIC METHOD, TROPAEOLIN 00.

Bisoprolol is a β blocker cardiovascular drug. It is structurally similar to metoprolol, acebutolol and atenolol in that it has two substituents in the para position of the benzene ring (fig.1) which might be the reason for its β1-selectivity.

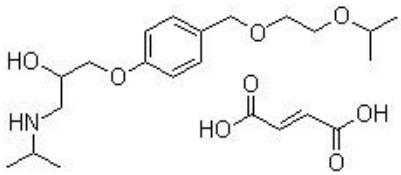

Fig. 1. The structural formula of bisoprolol fumarate

Bisoprolol is used for the treatment of hypertension, cardiac ischemia and congestive heart failure. This is also indicated for preventative treatment before and primary treatment after heart attacks thus reducing the chances of recurrence (1). Bisoprolol reduces the high blood pressure in hypertension, while in cardiac ischemia this drug is used to reduce the activity of the heart muscle and therefore reduce oxygen and nutrient demand, so reduced blood supply can still transport sufficient amounts of oxygen and nutrients (2-6).

Various methods such as UV-Vis spectrophotometry (7-10), high-performance liquid chromatography (11-13), and thin layer chromatography (14-16) are available for determination of bisoprolol in biological fluids and in pharmaceutical formulations.

The aim of the present work was to de-

velop a new rapid and reproducible spectrophotometric method for the quantitative determination of bisoprolol fumarate in pharmaceutical products.

MATERIAL AND METHODS

A Hewlett Packard 8453 double beam UV–Vis spectrophotometer equipped with 10 mm matched quartz cells was used in the present investigation. A Kern 770 analytical balance, an ultrasonic bath and a vibration shaker IKA-Werke type VX2 were also used.

The reagent used were: bisoprolol fumarate – 100.07% pure reference substance (Unichem Laboratories LTD, India), hydrochloric acid (Tunic Prod, Romania), dichloromethane (Fluka, Germany); tropaeolin 00 (Tunic Prod, Romania).

The pharmaceutical products Concor® (Merck), Bisotens® (Antibiotice Iasi) and Bisoblock® (Keri Pharma Generics Ltd) have been purchased from the local pharmacies.

Preparation of the solutions:

- stock solutions of bisoprolol fumarate was prepared by dissolving accurately weighed 10 mg of standard substance in a 100 mL volumetric flask with distilled water;
- standard solutions of various concentrations of bisoprolol were prepared by suitable dilution from stock solutions;
- 0.01% (m/v) aqueous solution of tropaeolin 00: 0.01 g of tropaeolin 00 was dissolve on ultrasonic bath in 100 mL volumetric flask with distilled water;
- 2M aqueous solution of hydrochloric acid was prepared by transferring 3.8 mL hydrochloric acid (96%) in 50 mL volumetric flasks and bringing up to the mark with distilled water;
- sample solution: twenty tablets of each formulation were accurately weighed and the average weight was calculated for each. These tablets were grounded to a fine powder. An accurately weighed tablet powder equivalent to 5 mg of bisoprolol fumarate was mixed with 30 mL of methanol and sonicated for 30 minutes. Insoluble excipients were separated through filtration. Then the solution was evaporated to dryness. The residue was dissolved into a 100 mL volumetric flask using distilled water. The obtained solution was diluted with distilled water to obtain working standard solution corresponding to 20 μg/ml.

Assay procedure: 1 mL 0.05 M hydrochloric acid and 1 mL 0.01% (w/v) tropaeolin 00 aqueous solution were added to 1 mL of bisoprolol fumarate solution with a concentration in between 5-30 μg/mL. The complex was then extracted using dichloromethane. Fifteen minutes later the absorbance was measured at 412 nm, using as reference a blank sample prepared in the same conditions.

Validation: The method was validated with respect to linearity, accuracy, precision and LOD and LOQ (17).

RESULTS AND DISCUSSION

The analysis of the absorption spectra (fig. 2) revealed a maximum absorbance of the reaction product at 412 nm. This value was used for all determinations.

As can be notice in fig. 3, bisoprolol in dichloromethane solution presented a maximum absorbance peak at 385 nm and tropaeolin 00 had no absorption peaks in the interest range.

Comparing the spectra from fig. 3 and 4, it was observed that the proposed method was selective because it had the ability to separate the signal of bisoprolol from the one corresponding to the reaction product.

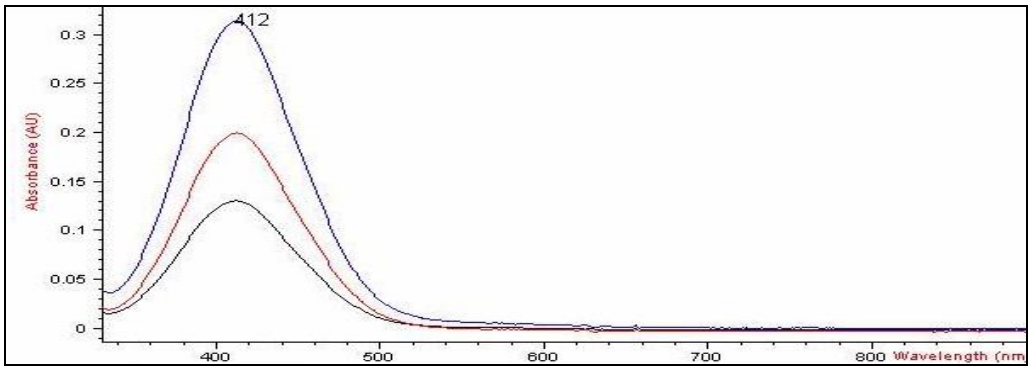

Fig. 2. Absorption spectra of the reaction product

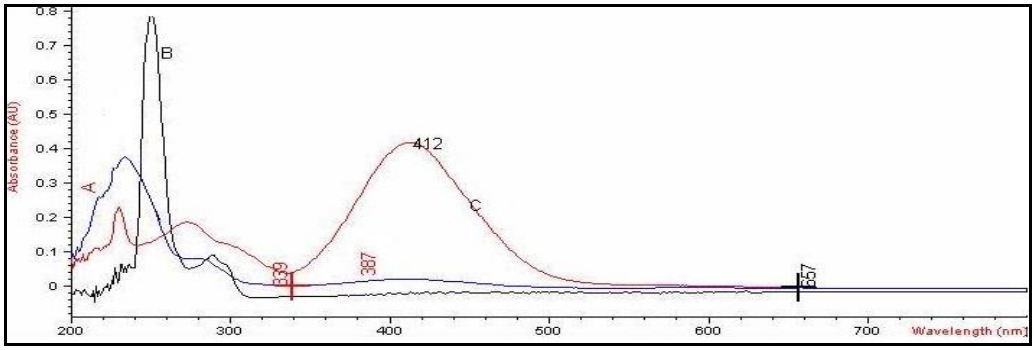

Fig. 3. Absorption spectra of bisoprolol (A), tropaeolin 00 (B) and reaction product (C)

The excipients used in the pharmaceutical formulation did not interfere the maximum absorption of bisoprolol complex.

While choosing the best solvent of the extraction, experiments were done using ethanol, methanol, chloroform, dichloromethane, acetonitrile (fig. 5). It has been observed that the best results were obtained when the extraction was performed using dichloromethane.

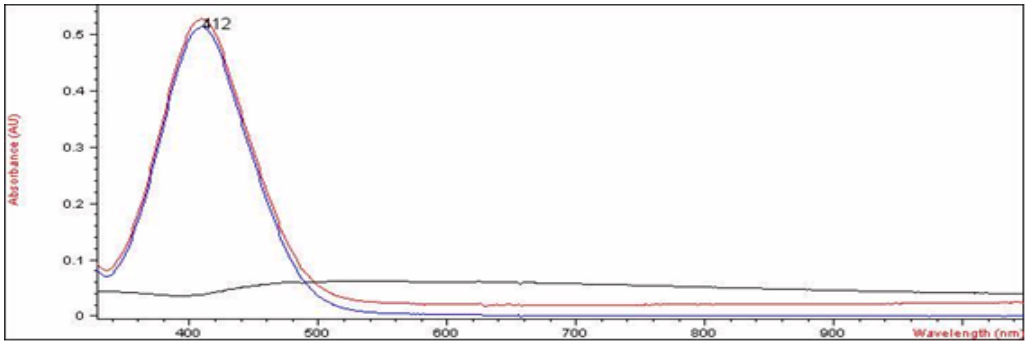

Fig. 4. Absorption spectra of placebo (1), sample solution (2) and standard (3)

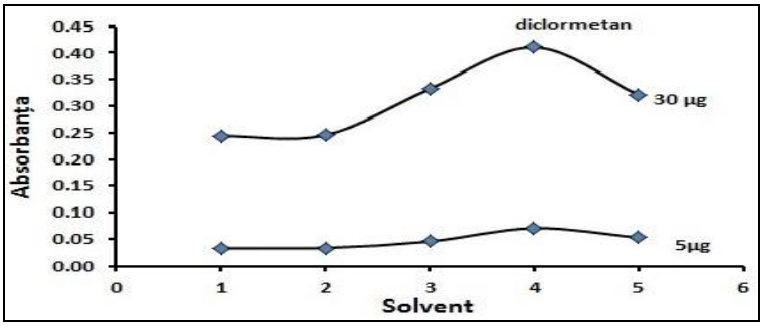

Fig. 5. Choice of solvent for the extraction

The calibration curves for bisoprolol fumarate was founded to be linear in the concentration range of 5-30 µg/mL. The optical and regression characteristics of the drugs are show below (tab. I).

The absorbance of each tablet formulations was measured and the results of analysis were shown in tab. II.

Accuracy: To study the accuracy of the proposed methods, recovery studies were carried out by adding a known amount of drug to the pre analyzed tablet powder and percentage recoveries were calculated. The result of recovery studies are presented in tab. III.

Precision: The reproducibility of the proposed method was determined by performing the analysis at different time moments in the same day (intra-day assay precision) and three different days (inter-day assay precision). The results of intra-day and inter-day precisions expressed in relative standard deviation percentages were found to be 0.8 and 0.9, respectively.

Limit of detection and limit of quantification: The LOD and LOQ were determined based on the standard deviation of the intercept and the slope of the calibration curves. LOD and LOQ for bisoprolol were found to be 0.67 µg/mL and 2.23 µg/mL respectively.

TABLE I

Optical and regression characteristics

Wavelength (nm)	412

Concor®	12	8	99.15	0.42
Bisotens®	15	5	98.87	0.96
Bisoblock®	17	3	99.23	0.26

*Mean for 3 determinations

CONCLUSIONS

The presented assay provides a simple, accurate, economical and convenient method for the analysis of bisoprolol using VIS spectrophotometry. Results of percentage recovery showed that the method was not influenced by excipients.

The method was validated and its sensitivity and precision proved the suitability of the proposed method for the routine estimation of bisoprolol in pharmaceutical formulations.

NEWS

NEW PROPERTIES OF SOME SUGARCANE CULTIVARS

The phenolic composition, antioxidant potential and DNA damage protecting activity of sugarcane (*Saccharum officinarum*) were investigated by Abbas *et al*. Sugarcane is a dietary source of flavonoids and it is used as functional food in many countries. In addition, it is an important cash crop of Pakistan. The sugarcane leaves are the main raw material for the sugar industry. The authors studied the juices and the water extracts obtained from the leaves of thirteen varieties of sugarcane. The antioxidant activity of sugarcane extracts and juices was evaluated using DPPH radical scavenging assay. In this assay, the extracts showed better antioxidant activity than the juices. The IC_{50} values ranged from 20.82 to 27.47 µg/mL for the leaves extracts and from 63.95 to values higher than 200 µg/mL for the juices. In the phosphomolybdenum assay, the juices showed a better electron-donating activity than the extracts. In this assay, the IC_{50} values ranged between 62.3 and 80.26 µg/mL (extracts) and 70.43 and 99.9 µg/mL (juices). The leaves extracts and juices showed strong ability to protect against DNA damage induced by hydroxyl radical generated in Fenton reaction. The high performance liquid chromatography (HPLC) analysis of extracts was also performed. Ferulic acid (14.63 ± 0.03 mg/g), cumaric acid (11.65 ± 0.03 mg/g), quercitrin (10.96 ± 0.02 mg/g), caffeic acid (9.16 ± 0.01 mg/g) and ellagic acid (9.03 ± 0.02 mg/g) were detected as major compounds into CPF-246 sugarcane leaves extract. The results of the study showed that these cultivars might be used not only as an accessible source of natural antioxidants but also as an ingredient in functional foods (Abbas SR, Sabir SM, Ahmad SD, Boligon AA, Athayde ML. Phenolic profile, antioxidant potential and DNA damage protecting activity of sugarcane (*Saccharum officinarum*). *Food Chem* 2014; 147: 10-16)

Alexandru Vasincu

BOOK REVIEW

NEUROFIZIOLOGIE. ROLUL UNOR NEUROTRANSMIȚĂTORI ŞI ZONE NERVOASE ÎN MODULAREA PROCESELOR COGNITIVE ŞI IMUNITARE

by Lucian Hrițcu,

Publishing House of the University "Alexandru Ioan Cuza" from Iaşi, 2011, 231 pages

Reviewed by Prof. Ursula Stănescu, Ph.D.

"*Neurophysiology. The role of neurotransmitters and nervous areas in cognitive and immune modulation*" by lecturer Lucian Hritcu, Ph.D. was published at the end of 2011 by the prestigious academic publisher "Alexandru Ioan Cuza" University Press. The monograph is a thorough and complex study of the highly topical issues of the implications of nervous areas, certain neurotransmitters in cognitive processes and defense function of the animal organism, being a model for the study of such issues for all those interested in similar researches.

Innovative research methods, many experimental variations of studied parameters, the richness of obtained original results and their interpretation in accordance with literature data highlight the scientific value of this work and reflect author's hard work, perseverance, scientific competence and passion.

Based on these considerations, the author conducted a complex work with a comprehensive content covering 231 pages, including numerous current theoretical and a wide range of personal results. The monograph is divided into six chapters. It includes 78 tables, of which 73 contain original data and 5 data in the literature, 91 clear and suggestive figures, and an extensive bibliography of 370 titles, of which 12 are personal papers of which some were published in prestigious foreign journals. Of these 12 scientific papers three were published in ISI journals, two in the European Journal of Pharmacology (IF = 2.516) and one in the Turkish Journal of Hematology (IF = 0.341).

The first chapter, entitled **The current state of research on neuroimmunomodulation**, presents some theoretical aspects of the innervation of primary lymphoid organs such as: bone marrow, thymus, and bursa of Fabricius, and secondary lymphoid organs: spleen, lymph nodes and gut-and bronchus-associated lymphoid tissue. Also presented in this chapter are hormone and neuropeptide receptors, the main characteristics of the specific receptors in the lymphoid organs, and other receptors, such as those for arginine vasopressin, vasoactive intestinal polipeptid and cytokines.

Chapter 2 deals with the **Correlations of the central nervous system neurotransmitters and the immune system** and highlights the key issues on three neurotransmitters: acetylcholine, norepinephrine and dopamine. Thus, the author presents some basic characteristics of acetylcholine chemical structure, biosynthesis, specific receptors and its implications in cognitive processes. As to adrenaline and noradrenaline, a series of features, source, receptors, role and implications of these catecholamines in immune and cognitive processes

are detailed. The effects of dopamine on cells involved in immune processes, such as thymocytes and lymphocytes, particularly neutrophils and macrophages are well documented.

In Chapter 3 **a number of genetic aspects about degradation of the neurotransmitter system** involved in some severe neurodegenerative diseases like Parkinson's disease, Alzheimer's disease and schizophrenia are discussed. The features of these diseases are presented with particular emphasis on the genetic changes associated with neuronal alteration, disruption of neurotransmitter system and immune capacity, drawing our attention on important issues unsolved so far.

In Chapter 4 **Materials and working methods** are detailed in order to facilitate the understanding and assessment of experimental results. Experimental results are a model and an important guide for all researchers in this field. Techniques, laboratory materials and experimental animals for the four categories of operations: neurosurgical interventions, cognitive performance assessment, calculation of the immune indices and assessment of the effects of acute and chronic stress are presented.

In Chapter 5, the author discusses a significant number of results of experiments **on ways to modulate learning and memory processes via cholinergic and dopaminergic receptors**. To highlight the role of these receptors in cognitive processes, the author used a logical approach managing specific agonists or antagonists of these receptors then observing the test results on cognitive performance.

Following the correlation between nervous structures involved in cognitive processes and those involved in animal body defense function, the author studied **the ways to modulate immune function under the influence of nervous and neurotransmitter areas under stress**, a large number of original results being presented in Chapter 6 of this monograph.

The monograph ends with **general conclusions**, concise and enlightening, highlighting the originality and value of the results.

The present monograph is addressed to undergraduate, postgraduate and doctoral students, also, academics and researchers in the fields of animal physiology, medicine, neurophysiology, neuroendocrinology, neuropsychiatry and neuroimmunology.

PREVENTIVE ATTITUDES TOWARDS INFECTION TRANSMISSION IN DENTAL OFFICES IN NORTHEAST ROMANIA (Abstract) **Aim**: The aim of this study was to evaluate the level of knowledge and the current attitudes towards infection control in the dental offices in the Northeast Romania. **Material and methods**: Questionnaire-based study conducted on 152 dentists aged between 25-65 years practicing in 6 Northeast Romania counties. The questionnaire included questions related to current infection control procedures and attitudes. Data were statistically analyzed using *SPSS 14.0* and chi-square test ($p<0.05$). **Results:** The majority of the dentists (83.6%) consider that universities should provide a substantial education regarding infection control through postgraduate courses, but 7.2% of the respondents are not sure about their usefulness. The clinical decision related to patient's treatment is influenced by his infectious status for 67.8% of the dentists. Of these, 19.1% have over 20 years of practice and 48.0% are females. Almost all dentists (93.4%), regardless of gender (96.4% females and 87.8% males) undergo periodic testing for blood-borne viral infections (hepatitis B, C and HIV). Full protective equipment is used for all the patients by 86.2% of the dentists, while 12.5% use it only for the infectious ones. 65.2% of the dentists use steam sterilization equipment (autoclave), and 80,8% use dry heat. The majority of the dentists (82.6%) believe that the patient must always be informed about the adopted infection control measures, but 21.7% declare to do so only in some particular cases. **Conclusions** Dentists knowledge and attitudes towards infection control must be improved by educational interventions in order to adhere to the European standards. **Keywords**: DENTAL OFFICE, INFECTION CONTROL, EDUCATION

Occupational health of oral health care personnel and patient safety are of particular importance warranting imposition of rigorous rules of professional conduct in view of meeting the European safety standards of healthcare in the dental office (1).

MATERIAL AND METHODS

In order to assess the attitudes towards infection prevention and control in dental offices in North-east Romania, in the interval January-February 2011 we conducted a questionnaire-based study involving 152 dentists, 62.4% women and 37.6% men, aged between 25 and 65 years, working at private dental offices in 6 counties of Moldova: Iasi, Botosani, Neamt, Suceava, Bacau and Vaslui.

This study was part of a market research survey conducted in 5 development regions

of Romania in order to identify the current situation and current needs in the field of prevention, ergonomics and management. (European Project "ergonomics, prevention, performance management in dentistry by adopting European Standards, Contract: POSDRU/81/3.2/S/55651).

The questionnaire included 21 questions with one or more correct answers on the attitude of physicians towards infection control procedures established in dental offices.

The results were interpreted according to gender and years of practice and compared with those obtained by a study covering all Romanian regions. Data were processed using *SPSS 14.0* system, and compared using Chi-square test ($p < 0.05$). The approval of the Ethics Committee of the University of Medicine and Pharmacy "Grigore T. Popa" Iasi was obtained.

RESULTS

Analysis of responses showed that the majority of dentists (83.6%) considered necessary a substantial education in infection control both during university studies and postgraduate education, but 7.2% of respondents were unsure about their usefulness. Comparing these results with those of the nationwide study, it came out that the percentage of those not giving great importance to this knowledge was significantly higher (7.2% versus 1.9%).

Therapeutic approach in clinical practice was influenced by patient's infectious status in 67.8% of the dentists. Of these, 19.1% had over 20 years of practice and 48.0% were women. These values are close to those reported by the nationwide study (57.0 %, 19.2% and 23.7%, respectively) (fig. 1).

Most dentists (82.6%) believe that patients should be constantly informed on infection control measures taken in the dental office, but 13.0% say they do so only in special cases.

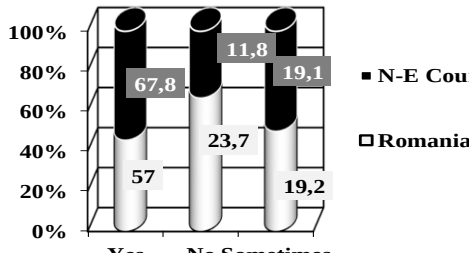

Fig. 1. Influence of patient's infectious status on therapeutic approach

Full protective equipment (gown, gloves, mask, goggles) is used for all patients by 86.2% of dentists, while 12.5% of them use it only for patients considered infected. Slightly more women (72.9%) use full protective equipment than men (68.4%). Nationwide data were: 90.2% and 9.8%, respectively (fig. 2).

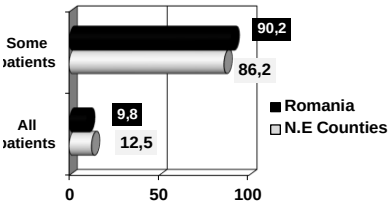

Fig. 2. Use of full protective equipment

In North-east Romania 98.9% of dentists use rubber gloves, 98.6% masks, and 53.9% goggles.

62.2% of doctors are immunized against hepatitis B. The majority of physicians (93.4%), with no significant gender difference (96.4% women and 87.8% of men) say they carry out periodic testing for blood-borne diseases (hepatitis B, hepatitis

C, HIV infection).

As to sterilization methods, 80.8% of the dentists use dry heat sterilization (Poupinel), 65.2% moist heat (autoclave), and 8.7% resort to chemical sterilization (fig. 3). Data obtained for Romania were 63.5%, 75.5% and 8.9%, respectively.

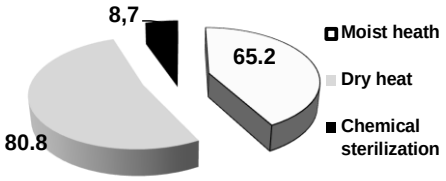

Fig. 3. Sterilization methods used in Northeast Romania dental offices

Hand hygiene, essential for infection control in healthcare facilities, is performed before applying protective gloves (22.5% of dentists), before each patient (60.5%) after each patient (56.3%), whenever necessary (66.3%).

Ultraviolet light devices are used to control air contamination in 28.1% of dental offices.

The methods of decontamination of dental unit waterlines were: water circulation in the water systems at the beginning of the working day and between patients (27.5%), use of distilled water (20.7%), water sterilization (3.4%), and germicidal agents (12.4%) (fig. 4).

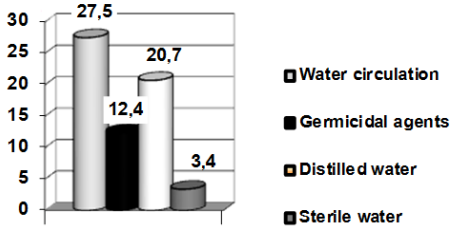

Fig. 4. Methods of decontamination of dental unit waterlines

DISCUSSION

Assessment of adherence to infection control recommendations is essential for estimating the safety and predictive risk factors for patients and medical staff in dental offices.

Immunization is an important measure in the dental office occupational protection, as the oral healthcare personnel belongs to a risk category due to direct contact with blood or other body fluids. The study results show a small percentage of dentists immunized against hepatitis B (62.2%) compared with data reported in the literature: 93% - USA, 91% - Canada, 86% - England (2).

Hand hygiene is considered the most effective measure to reduce the risk of transmission of pathogens in healthcare facilities (3). Our results show that only 25% of the dentists wash their hands or use hand sanitizers before applying protective gloves although these do not provide complete protection against pathogen (4).

Protection provided by the use of protective equipment is scientifically substantiated and is one of the basic rules of Universal Precautions (5). Goggles and masks significantly reduce mucosal exposure, and gloves are remarkably effective in reducing occupational exposure to diseases transmitted via blood at hand skin level (6, 7). The evaluation of doctors' attitudes demonstrated a good compliance (86.2%) in wearing full protective equipment (gown, mask, goggles, gloves) used with all patients regardless of infectious status or clinical procedure. The results show an increase in the compliance level compared with than reported by Bârlean et al. (full equipment: 68.4%) (8). A lower proportion of physicians (53.9%) use goggles ignoring the risk of infection transmission to the eyes.

Devices used to sterilize dental instru-

ments are mainly represented by dry-heat autoclave (80.8%), but the number of dentists using moist heat autoclave is increasing (65.2% compared to 40.2% in our 2007 study) (9). Although guidelines and recommendations of the European organizations restrict chemical sterilization in dentistry, our study shows that 8.7% of the dentists in Northeast Romania and 8.9% in all Romania use of this method (10).

Control of dental unit waterlines contamination is not a major concern for dentists as only 12.3% of them use germicidal products for decontamination (11).

The comparative assessment of the results showed that the level of knowledge and current practices of infection control of the dental practitioners in Northeast Romania corresponds to the levels revealed by the study in 5 development regions of Romania.

CONCLUSIONS

Assessing current attitudes and practices regarding infection control procedures in dental offices in the Northeast Romania has shown the need to promote a realistic perception of the risk of infection transmission and to implement specific measures for the protection of oral healthcare personnel and patients in view of adhering to the European standards.

CLINICAL-RADIOLOGICAL STUDY ON THE ROLE OF BIOSTIMULATING MATERIALS IN IATROGENIC FURCATION LESIONS (Abstract): Root perforation is an unwanted incident which may occur at any stage of endodontic treatment and can adversely affect tooth prognosis. **Aim**: To compare the recovery rate after treatment of root perforations in the interradicular area of the molars, using two different materials: MTA and ceramic nanoparticles mineral cement DiaRoot® BioAggregate, by a clinical-radiological and statistical analysis over a period of up to 24 months. **Material and methods:** The study was conducted on 28 molars from patients of both sexes, mean age 33.29 ± 6.2DS, with iatrogenic perforation of pulp chamber floor. The teeth were divided into 2 groups according to the applied material: group 1 - gray MTA (ProRoot ® MTA, Dentsply, Tulsa Dental), and group 2 - BioAggregate (Diadent ® Group International, Vancouver). Patients included in the study were monitored and assessed by radiological examinations at 6, 12 and 18 months. **Results:** Pulp chamber floor perforations are significantly associated with tooth location ($\chi 2 = 35.60$, $r = 0.67$, $p = 0.00359$, 95% CI). Both when the perforation was repaired with MTA and BioAggregate, the clinical improvement was significant ($\chi 2 = 17.608$, $r = 0.58$, $p = 0.0035$, 95% CI). **Conclusions:** Based on the results of this study, both MTA and BioAggregate are excellent materials for root perforation repair**. Key words:** ENDODONTIC TREATMENT, ROOT PERFORATION, REPAIR MATERIALS.

Endodontic treatment is a delicate clinical procedure, unfortunately resulting sometimes in failures. Root perforation is an unwanted incident which may occur at any stage of endodontic treatment and can adversely affect tooth prognosis. Although caries or resorption processes may also cause this type of tissue destruction, most root perforations are iatrogenically induced. Perforations usually produce an artificial communication between the radicular canal and the periodontal space. They can be located at different levels of the root, from the accidental perforation of the pulp chamber floor to the side walls of the canal, continuing to the root apex, with inflammatory and resorptive implications. Numerous research papers show the possi-

bility of applying modern techniques and materials to restore damaged structures, based on animal experiments and histological studies (1, 2).

In addition to providing a good seal, the material of choice for root perforation repair must be biocompatible, nontoxic, insoluble in the presence of tissue fluids, and able to promote periradicular tissue regeneration. Untreated, perforation results in a chronic inflammatory reaction of the periodontium, sometimes with serious complications, such as suppuration, abscess, fistula or bone resorptive processes that can lead to irreversible loss of tooth attachment. Seltzer et al. (4) have shown that successful root perforation repair is conditioned by their location, shape, size, and the time before sealing.

This study aimed at comparing the recovery rate after root perforation treatment with two different materials: MTA (ProRoot ® MTA, Dentsply, Tulsa Dental) and DiaRoot ® BioAggregate (Diadent ® Group International, Vancouver), by a clinical-radiological and statistical analysis conducted over a period of up to 24 months.

MATERIAL AND METHODS

The study was conducted on 28 molars (12 maxillary and 16 mandibular) from 28 patients (13 female and 15 male) aged between 25 and 46 years with an average of 33.29 ± 6.2 DS. The patients presented to our office for a root canal treatment due to a symptomatic tooth or iatrogenic maneuvers performed in the past. All cases were evaluated before and after treatment by a double blind study to determine the presence or absence of pathological changes surrounding the perforation site. The 28 molar were randomly divided into 2 equal groups: in group 1 we used gray MTA (ProRoot ® MTA, Dentsply, Tulsa Dental), and in group 2 BioAggregate (Diadent ® group International, Vancouver), both mixed to a paste consistency according to manufacturer's instructions.

After tooth isolation and cavity cleaning, the communication between pulp chamber and periodontal space was detected and in case of bleeding hemostasis was achieved using cotton pellets soaked in 5% sodium hypochlorite. The material was applied with a special carrier, (MTA- gun) and then easily condensed with a plugger. Over it a pellet soaked in distilled water was placed, because both materials are setting in a wet environment and finally provisional cement (Citodur, DoriDent, Austria) for 2-3 days. At the next visit, the provisional cement was removed, MTA strength and the degree of perforation coverage were checked with a palpation probe, followed by the standard mechanical, chemical and drug treatment of root canals.

RESULTS

After physical examination, history taking, and interpretation of radiographic images, the data were recorded in case-record forms including all relevant radiographs. The analysis showed that of the studied 28 teeth, 10 presented untreated pre-existing perforations with associated chronic periapical pathology, 7 presented perforations previously incorrectly and ineffectively treated with persistent interradicular radiolucency, and 11 perforations made during endodontic treatment or retreatment (fig. 1).

Of all study patients, 16 (6 upper molars and 10 lower molars) had a radiolucency at the furcal area on the initial radiograph, accompanied by painful symptoms, confirming the presence of chronic inflammation in that area (fig. 2)

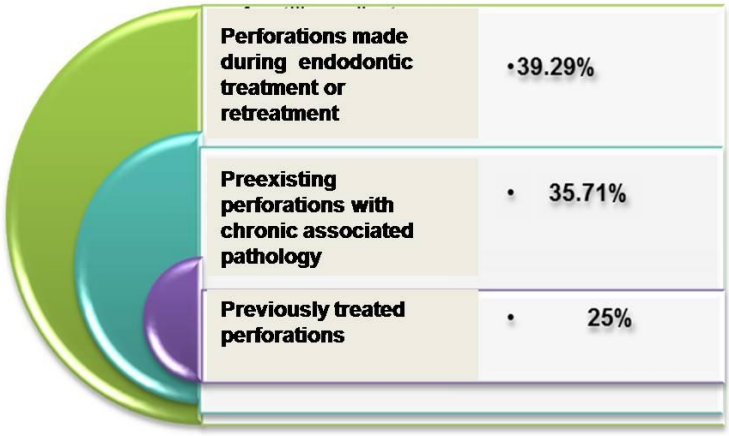

Fig.1. Case distribution according to the cause of root perforation

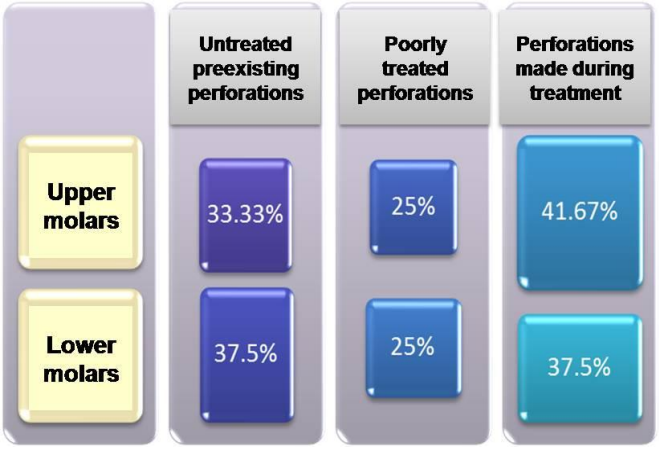

Fig. 2. Initial situation of perforations in molars

Of the 12 upper molars studied, 6 presented perforation of the pulp chamber floor located in the disto-buccal area, 2 perforations located in the mesio-buccal area, and 4 central perforations. In the mandible, of the 16 studied molars, 7 perforations were located medially, 5 distally, and 4 centrally. The statistical analysis showed that there is a significant association between pulp chamber floor perforation and tooth location (χ^2 = 35.60, r = 0.67, p = 0.00359, 95% CI); thus, in the upper molars perforations are more frequent in the disto-buccal area,(21.43%), while in the lower molars in the mesial area (25%) (fig. 3).

The cause of pulp chamber floor perforations was significantly correlated with tooth type, as demonstrated by the higher frequency of untreated pre-existing perforations in the lower molars (37.5%), and perforations made during endodontic treatment especially in upper molars (χ^2 = 26.505, r = 0.59 , p = 0.00547, 95% CI) (fig. 4).

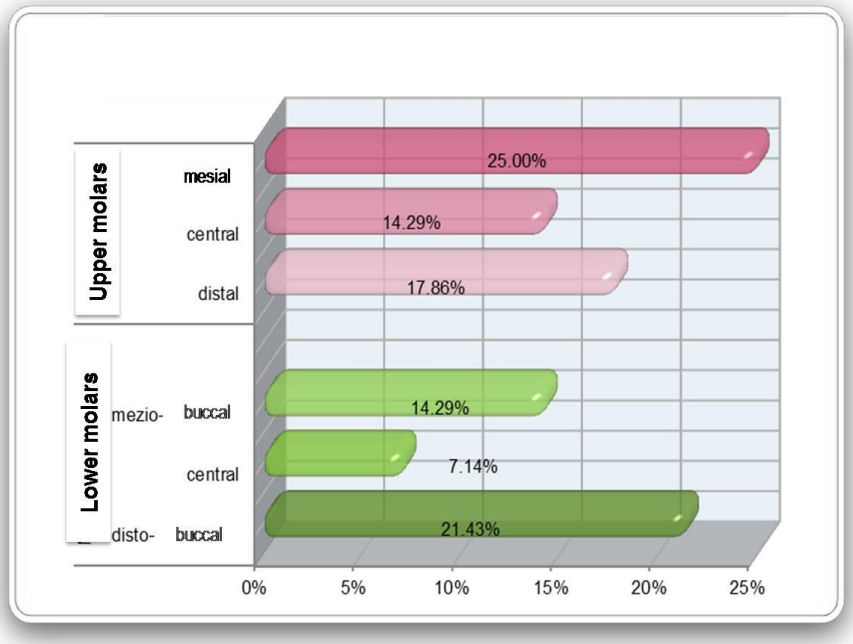

Fig. 3. Case distribution according to the location of pulp chamber floor perforation
La lower molars - mesio-

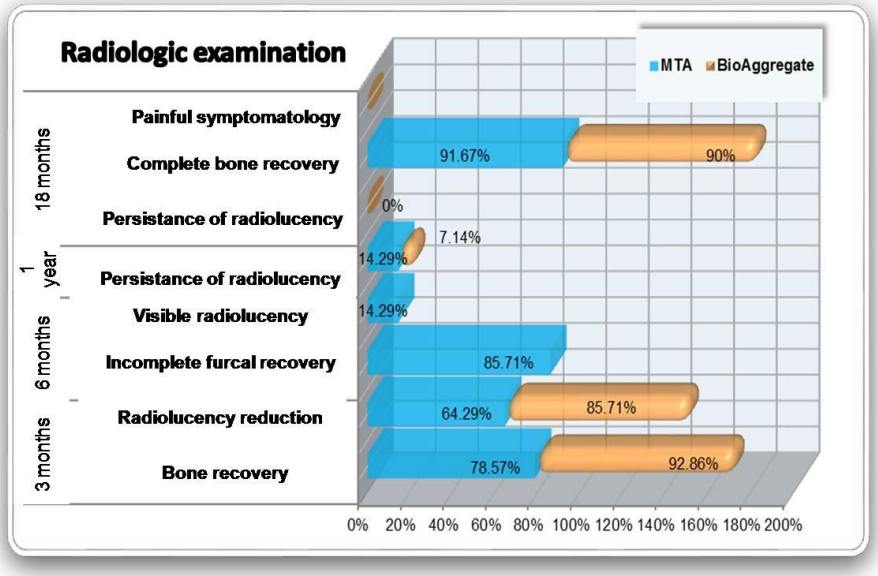

Fig. 4. Radiological examination of pulp chamber floor perforations

One-year postoperatively, all molars in group 1 were asymptomatic, had no attachment loss or fistula. Radiological examination revealed, however, in two cases, the persistence of a radiolucent furcal area in molars with larger initial lesions (one lower and one upper). The same was seen in group 2 molars, except for one case, with a larger initial lesion, that still had an area of osteolysis, lesser than the initial one, accompanied by mild pain when chewing (fig. 5).

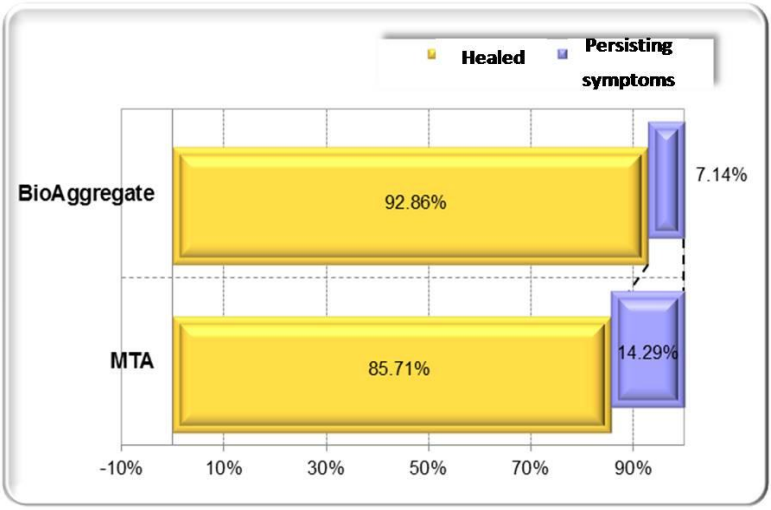

Fig. 5. Association of the type of repair material with postoperative course

Radiological images showed better results especially in group 2, where the used material was BioAggregate. Thus, the type of repar material significantly influenced the postoperative course (χ^2 = 6.15, r = 0.46, p = 0.03, 95% CI).

To illustrate the ability of the above mentioned materials to induce periradicular tissue recovery and healing, we here mention one of the cases included in this study. A 42-year-old female patient was referred to the clinic for a mild pain when chewing in the lower left molar. After the removal of the massive crown restoration a 1.5-2 mm communication area between the pulp chamber and the furcal periodontium was seen. Radiologically, a large interradicular radiolucent area was revealed, implying the presence of a local irritation factor. The tooth was treated with BioAggregate cement, according to the protocol used in all group 2 teeth (fig. 6)

DISCUSSION

The main goal in the treatment of root perforations is stopping further loss of periodontal attachment by preserving healthy tissue at the perforation site. Several studies (5, 6, 7) have shown that if the lesion is already present, it is important to restore the attachment tissue. It was found that important factors in determining the success of a perforation repair procedures are perforation location, time between the occurrence of perforation and its repair. The results of this study are consistent with those obtained by other authors in their research on similar subject (8, 9).

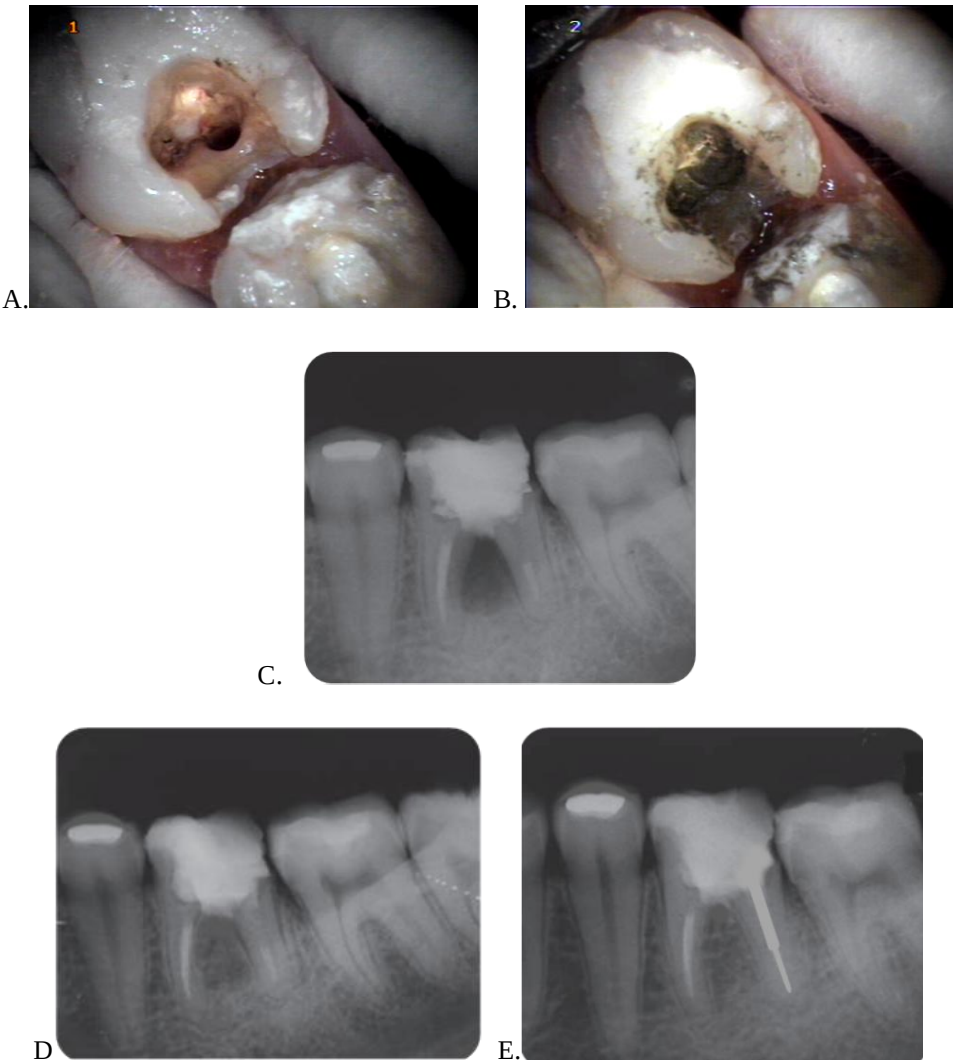

Fig. 6. A. Lower left molar with restorative material and pulp chamber floor perforation. **B.** MTA application over the communication. **C.** Preoperative radiograph shows an incomplete endodontic treatment and a well defined interradicular radiolucency. **D.** The 6 months radiograph indicates a reorganization of demineralized trabecular bone with furcal recovery. **E.** The radiographic exam after two years shows complete healing of interradicular and periradicular bone with complete restoration of the periodontal space.

CONCLUSIONS

Researches have shown that treatment plan for perforation repair depends on the visibility and accessibility of perforation, its size, periodontal status, and strategic importance of the tooth. Successful repair of root perforations is conditioned by its the location, shape, size, and the time be-

fore it is sealed. One of the most important parameters affecting treatment outcome have proved to be the location on the root surface and the type of repair material, which appears to significantly influence the postoperative course.

INCRETIN MODULATORS, A NEW PERSPECTIVE IN DIABETES MELLITUS TREATMENT (Abstract): **Aim:** The study was designed to present the modern therapy used for the treatment of type 2 diabetes mellitus (T2DM). **Material and methods**: Diabetes mellitus and the pharmacological and the pharmacokinetic characteristics of the incretins and of the incretin modulators are presented. **Results**: Diabetes mellitus is a chronic metabolic disorder, which is considered to be a major health issue all over the world. World Health Organization indicates that world-wide almost 3 million deaths per year are caused by diabetes and 1,5 million new cases are diagnosed annually, T2DM representing approximately 90-95% of the diagnosed cases. This form of diabetes mellitus is characterized by several path physiological defects including insulin resistance at peripheral target tissues, excess hepatic glucose production and progressive pancreatic beta cell dysfunction. The newest direction in the treatment of T2DM mellitus is the incretin modulators. The incretins (GLP-1 - glucagon-like-peptide-1 and GIP - glucose-dependent insulin tropic peptide), are natural hormones that contribute to glucose homeostasis by acting on the pancreas, gastrointestinal tract, muscle and brain tissue. After secretion, GLP-1 and GIP are immediately metabolized by dipeptidyl peptidase IV enzyme (DPP IV), which limits their therapeutic use. **Conclusions:** In order to achieve optimal glycemic control, by using the therapeutic effects of incretins, research has been directed to the development of synthetic analogues of GLP-1 resistant to DPP IV enzyme inactivation and DPP IV inhibitors. **Key word**: DIABETES MELLITUS, INCRETINS, DIPEPTIDYL PEPTIDASE

Diabetul zaharat (DZ) este definit ca fiind un grup de boli metabolice caracterizate prin hiperglicemie, datorată deficienţelor în procesul de insulino-secreţie controlat de pancreas, sau perturbărilor în a utiliza insulina endogenă, sau a ambelor (1).

Ţinând seama de factorii etiologici implicaţi, sunt recunoscute două forme de DZ, cel de tip 1 (insulino-dependent, DZ 1) caracterizat prin distrugerea celulelor beta pancreatice producătoare de insulină din insulele Langerhans şi cel de tip 2 (diabetul non - insulino dependent, DZ 2), rezultând o perturbare cronică a metabolismului, în principal, asociată cu rezistenţa la insulină în ţesuturile ţintă, producerea în exces de glucoză în ficat şi rezistenţa la insulină în muşchii scheletici, ficat şi în ţesutul adipos (1).

Terapia clasică a DZ 2 dispune de patru

categorii de agenți farmacologici: sulfoniluree şi glinide, care stimulează secreția de insulină în celule beta pancreatice; biguanide, care întârzie absorbția glucozei; tiazolidindione, care cresc efectele insulinei prin reducerea rezistenței în țesuturile periferice (ficat, muşchi); inhibitori ai alfa-glucozidazei, care întârzie absorbția glucozei şi reduc secreția postprandială de glucoză prin inhibarea glucozidazei, prezentă în celulele mucoasei intestinale.

Deşi eficient, tratamentul DZ tip 2 poate fi asociat cu efecte secundare (hipoglicemie, creştere în greutate, edeme, afectare renală, hepatică şi gastrointestinală, acidoză lactică, anemie, etc.) care deseori pun în pericol viața pacientului.

NOI ȚINTE ÎN TERAPIA DIABETULUI ZAHARAT

Cea mai nouă şi modernă opțiune terapeutică în tratamentul DZ tip 2, o constituie modulatorii *incretinelor* – analogii sintetici ai GLP-1 (glucagon-like-peptide-1) şi inhibitorii dipeptidil peptidazei IV (DPP-IV) (2).

Incretine. Sub denumirea de incretine, se cunosc doi hormoni endogeni cu structură peptidică - GLP-1 (glucagon-like-peptid-1) şi GIP (glucose-dependent insulinotropic peptide), care contribuie la homeostazia glucozei acționând asupra pancreasului, tractului gastro-intestinal, țesutului muscular şi creier.

Mecanismul, care stă la baza efectului incretinic, este reprezentat de eliberarea imediată din celulele intestinale, ca răspuns la ingestia alimentelor, a celor doi hormoni, care la rândul lor stimulează secreția de insulină în celulele beta pancreatice. Se apreciază că 50-60% din insulina totală secretată în timpul mesei se datorează celor doi hormoni (2).

Pe lângă stimularea secreției de insulină, GIP şi GLP-1 au şi alte efecte fiziologice: inhibă secreția de glucagon (hormon secretat de către pancreas care creşte concentrația glucozei în sânge) la nivelul celulelor alfa (GLP-1), creşte proliferarea şi reduce apoptoza celulelor beta (GLP-1, GIP), creşte saţietatea şi reduce greutatea corporală (GLP-1) şi întârzie golirea stomacului (GLP-1) (2).

Dipeptidil peptidazele (DPP) reprezintă o familie de serin proteaze, care scindează diferite peptide în proteine, la nivelul aminoacidului serină. Din această familie fac parte, DPP I-IV, FAP (fibroblast activation protein-α), DPP VIII şi DPP IX (3).

După secreție, GIP şi GLP-1 sunt rapid metabolizați de către DPP IV, timpul de injumătățire al acestora fiind de 5 minute (GIP) şi respectiv de 2 minute (GLP-1). Inactivarea se produce în proporție de peste 50% la nivelul capilarelor intestinale, aproape de locul de eliberare a celor doi hormoni, fapt care limitează utilizarea acestora în scop terapeutic (4).

În scopul obținerii unui control glicemic optim, folosind efectele benefice ale incretinelor, s-a reuşit dezvoltarea a două noi clase de agenți terapeutici (2): analogi sintetici ai GLP-1, rezistenți la inactivarea enzimatică produsă de DPP IV şi inhibitori ai DPP IV, care blocând enzima, prelungesc timpul de acțiune al peptidului, acționând fiziologic asupra secreției glucozo-dependentă de insulină şi glucagon.

Analogi sintetici ai GLP-1. Cercetările derulate în grupul analogilor sintetici ai GLP-1, au fost încununate de succes prin introducerea în terapeutică în aprilie 2005 a Exenatidei, un polipeptid constituit din 39 de aminoacizi (Byetta, sol. inj. 5μg, stilou injector). Acest medicament suprimă secreția de glucagon, creşte secreția de insulină într-o manieră glucozo-dependentă, întârzie

golirea stomacului şi reduce pofta de mâncare. Exenatida restabileşte secreţia de insulină şi activează proliferarea celulelor beta (2) (fig. 1).

Un alt analog sintetic al GLP-1, introdus în terapeutică în 2009, este Liraglutida (Victoza, sol. inj. 6 mg/ml, stilou injector). Acesta este derivatul palmitoil al GLP 1, cu acţiune de lungă durată, având un timp de înjumătăţire de 11-15 ore. Asemănător Exenatidei, Liraglutida reduce concentraţia plasmatică de glucoză prin stimularea activităţii celulelor beta pancreatice cu creşterea concentraţiei de insulină şi reduce activitatea celulelor alfa pancreatice cu scăderea concentraţiei de glucagon (2) (fig. 2).

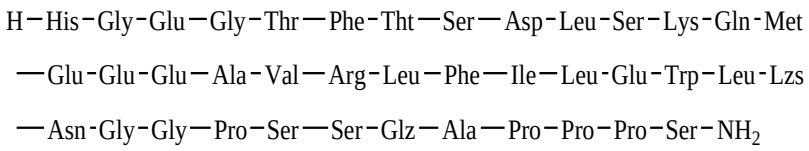

Fig. 1. Structura chimica a Exenatidei

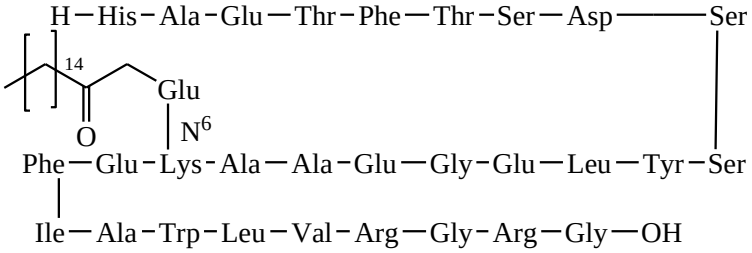

Fig. 2. Structura chimica a Liraglutidei

Inhibitori ai DPP IV. Primele cercetări în direcţia inhibitorilor dipeptidil peptidazei IV datează din 1996, când s-a confirmat *in vivo* acţiunea acestora de reducere a concentraţei de glucoză; studiile suscitând interese considerabile în industria farmaceutică (3).

Inhibitorii DPP IV suprimă degradarea unor peptide bioactive, incluzând GLP-1 şi GIP, ceea ce are drept rezultat creşterea duratei lor de acţiune (T1/2). În experimentele pe animale de laborator, inhibitorii DPP IV au redus activitatea enzimei cu până la 90%. Studiile clinice, au arătat că inhibitorii DPP IV reduc atât nivelul glucozei „*à jeun*" cât şi a glucozei postprandiale şi stimulează activitatea celulelor beta pancreatice (4).

Din punct de vedere structural inhibitorii DPP IV pot fi cu structură peptidică şi non-peptidică, iar la rândul lor inhibitorii peptidici, pot fi încadraţi în trei clase: inhibitori analogi reversibili (pirolidine, tiazolidine – P32/98, PSN 9301 (Prosidion) şi MK-432; inhibitori analogi acţionând covalent (cianopirolidine - NVP DPP 728, LAF 237 -Vildagliptina, BMS-477118 - Saxagliptina, ABT-279); şi inhibitori heterociclici non-peptidici reversibili (xantine, aminometilpirimidine) (4).

Dintre aceştia, terapeutica beneficiază deja de patru reprezentanţi, Sitagliptina fosfat aprobată de FDA (*Food and Drug Administration*) în octombrie 2006, Vilda-

gliptina ce a primit aprobarea EMA (*European Medicines Agency*) în septembrie 2006, Saxagliptina ce a primit aprobarea de punere pe piață pe 1 octombrie 2009 şi Linagliptina ce a primit aprobarea FDA în mai 2011 (fig. 3).

Alți inhibitori ai DPP IV se află în studii clinice avansate, printre aceştia numărându-se Alogliptina (aflată în faza III a trialului clinic), PF-00734200, LAF237 (Novartis Pharmaceuticals), P32/98 (Probiodrug şi Merk Company) aflat în faza I a trialului clinic, MK-0431 (Merck Company şi Bristol-Myers Squibb) intrat în faza III a trialului clinic în 2004 (3, 4) (fig. 3).

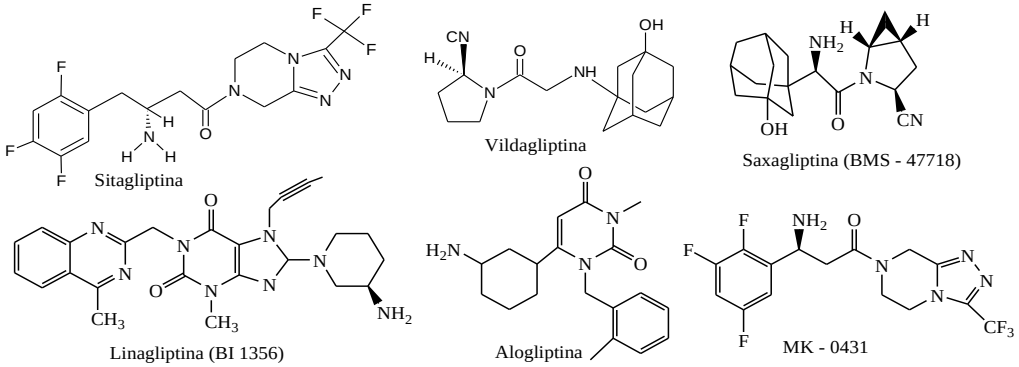

Fig. 3. Structura chimică a unor inhibitori ai DPP IV

Vildagliptina (Galvus, Novartis) este un inhibitor potent, selectiv şi competitiv al DPP IV, activ la administrare orală. Administrat pacienților cu DZ tip 2, în doză de 100 mg/mg, timp de 4 săptămîni, reduce semnificativ concentrația glucozei în sânge (cu 1.4 mmol/L postprandial) (5). Sitagliptina a fost aprobată de FDA ca monoterapie (Januvia, Merck™ & Co) şi în asociere cu Metformin (Janumet, Merck™ & Co) (6). Multe studii au arătat că atât sitagliptina cât şi vildagliptina au o siguranță ridicată şi sunt bine tolerate ca terapie combinată sau ca monoterapie, având o incidență scăzută a efectelor adverse incluzând: hipoglicemie, creştere în greutate, afecțiuni gastro intestinale.

Saxagliptina (Onglyza, Bristol Myers Squibb, Astra Zeneca) este un cianopirolidin inhibitor, cu acțiune de lungă durată şi cu stabilitate crescută comparativ cu Vildagliptina. Se administrează în doză de 2,5-100 mg/mg ca monoterapie sau ca terapie combinată în asociere cu metformin (7).

Cel mai recent inhibitor al DPP IV introdus în terapeutică este Linagliptina (Ondero, Boehringer Ingelheim International) ce este rezultatul unor intense cercetări, ce au avut drept obiectiv modulări structurale pe nucleul xantinic şi evaluarea acestora asupra capacității de inhibarea a activității enzimei DPP-IV. Linagliptina este un inhibitor nonpeptidomimetic cu acțiune de lungă durată, bine tolerat, sigur şi cu risc redus de hipoglicemie. La doze terapeutice (5 mg/zi), produce inhibarea activității DPP IV în proporție de 50%, fiind mai activă decât vildagliptina, sitagliptina şi saxagliptina (8).

CONCLUZII

Terapia cu antidiabetice orale cuprinde sulfoniluree, glinide, biguanide, tiazolidin-

dione şi inhibitori de alpha-glucozidază. În ciuda eficienței lor terapeutice, controlul glicemic al pacienților cu DZ tip 2, se deteriorează progresiv. Speranța bolnavilor de DZ tip 2 vine din partea modulatorilor incretinelor, şi îndeosebi a analogilor sintetici ai GLP-1 şi a inhibitorilor de DPP IV, ce au dovedit un profil farmacologic şi o siguranță terapeutică mai bună comparativ cu antidiabeticele orale existente.

GEOGRAPHICAL DISTRIBUTION OF HUMAN PAPILLOMAVIRUS AND THEIR CORRELATION WITH CYTOLOGIC ABNORMALITIES IN CERVICAL LESIONS AND WITH THE AGE IN A FEMALE POPULATION FROM TRANSILVANIA (Abstract): Cervical samples from 182 females aged 16-63 years were tested between 2008-2011 for human papillomaviruses (HPV) using PCR methods through the reverse hybridization and Roche genotyping. In 99 (54.4%) cases, different types of HPV were detected in 53 (53.5%) single infections and in 46 (46.5%) multiple infections, frequent in urban (94 cases: 50 single infections and 44 multiple infections). 32 different types of HPV were identified, 15 types being with high-risk. There were only seven rural patients, having single infections with the types 51, 58, 84; multiple infections with three or more than three associated HPV were not found. The most frequently identified was type 16 with high-risk, both in urban and rural areas, prevalent at 20-30 years of age. The types 35, 39, 59, 68 with high-risk were isolated only from multiple infections. Of the 9 females of rural origin investigated through cytological examination Babeş-Papanicolaou, the types 16, 31, 58 (with high-risk) were detected in five cases. 42 (42.4%) cases with HPV infections were found in females aged 20 to 25 years. The frequency of HPV infection decreases with the age. The mean of age is significantly increased in females without infection (p=0.00007) and it is significantly decreased in females with multiple infections, as compared with those with single infections or without infections. The females with single infections have the average of age significantly lower, as compared with the females free of HPV infections. There is a significant correlation between the age and the total risk of HPV infection (the age increase and the total risk decrease). **Key words:** HPV, PCR, AGE, CYTOLOGICAL EXAMINATION, URBAN, RURAL.

Virusurile Papilloma umane (HPV; familia *Papovaviridae*) constituie un grup foarte heterogen de virusuri ADN de talie mică (circa 55 nm). Se cunosc peste 130 de genotipuri de HPV. Rolul lor în patologie este recunoscut pentru câteva genotipuri (peste 40 identificate în tractul genital feminin) (1, 2). La om, HPV infectează celulele epiteliale ale pielii şi mucoaselor, determinând o gamă variată de leziuni proli-

ferative, nu şi litice (3, 4). După aspectul clinico-patologic şi structura genetică, HPV sunt împărţite în tipuri cu risc scăzut (HPV 6 şi 11 sunt cele mai comune), care produc condiloame acuminate, respectiv tipuri cu risc crescut (oncogene), HPV16 şi HPV18 fiind cele mai cunoscute ca asociate cu cancerul de col uterin, cauzând aproximativ 70% din cancerele cervicale în întrega lume (2, 4). Unele din virusurile specifice pentru mucoasa genitală, în special HPV 6 şi 11, pot infecta şi alte mucoase (tractul respirator, cavitatea bucală, conjunctiva) (2). Răspunsul imun faţă de HPV este specific de tip (5). Infecţiile cu mai multe tipuri de HPV par să acţioneze sinergic în carcinogeneza cervicală (6). Infecţia cu HPV este considerată cea mai frecventă infecţie cu transmitere sexuală (ITS) (2, 7), prevalenţa infecţiei cu HPV la adulţii tineri fiind de 20-50% (6). Cancerul cervical este a doua cauză frecventă de deces prin cancer la femeile din întreaga lume (8). Stabilirea prevalenţei infecţiei cu HPV în diferite tipuri de leziuni cervicale este deosebit de importantă, ca şi evidenţierea relaţiei dintre HPV şi gravitatea leziunilor cervicale (6). Vaccinarea poate reduce apariţia cancerului cervical cu 70% şi a neoplaziei intraepiteliale cervicale cu 50% (4).

MATERIAL ŞI METODE

În perioada 2008-2011 am examinat secreţii cervicale recoltate de către medici ginecologi de la paciente în vârstă de 16-63 de ani din mediul urban şi rural, efectuând genotiparea HPV şi examenul citologic Babeş-Papanicolaou (frotiuri colorate) la 39 de femei în vârstă de 16-60 de ani în perioada 2008-2009 şi 143 de femei cu vârsta de 19-63 de ani în perioada 2010-2011.

Pentru a identifica genotipul de HPV prezent în probe şi a ierarhiza riscul oncogen al tulpinilor HPV a fost utilizată tehnica PCR:

1. Tehnica PCR de hibridizare inversă (testul INNO-LiPA HPV Genotyping *Extra*– de la INNOGENETICS), utilizată în anul 2008. Testul permite decelarea a 28 de genotipuri de HPV (9);

2. Tehnica PCR (metoda de genotipare Roche – kitul Linear array HPV genotyping test), utilizată în perioada 2010-2011, care poate detecta 37 de tipuri de HPV (10).

Examenul citologic Babeş-Papanicolaou a fost interpretat în conformitate cu criteriile Sistemului Bethesda 2001 pentru evaluarea frotiurilor cervico-vaginale.

La prelucrarea statistică a rezultatelor am utilizat testul *t-Student* pentru compararea a două medii cu distribuţie de probabilitate normală, iar în cazul în care nu a existat o distribuţie normală a fost utilizat testul Mann-Whitney. Pentru a compara mai mult de două medii cu distribuţie de probabilitate normală a fost utilizat testul ANOVA. Pentru testarea distribuţiei normale am folosit testul Kolmogorov-Smirnov. În cazul în care nu a existat o distribuţie normală a fost utilizat testul Kruskal-Wallis. Pentru compararea a două frecvenţe a fost utilizat testul χ-pătrat sau Fisher-exact în cazul în care frecvenţele teoretice sunt sub 5. Analiza de corelaţie între variabile continue a fost efectuată prin calcularea coeficienţilor de determinare şi ecuaţia dreptei de regresie. Pragul de semnificaţie pentru testele folosite a fost luat p = 0,05. Calculele statistice au fost efectuate cu ajutorul aplicaţiilor *SPSS 13.0*.

REZULTATE

Examenul citologic Babeş-Papanicolaou a fost efectuat la nouă paciente; la patru (din mediul urban) nu a fost identificat nici

un tip de HPV, însă s-au constatat: modificări reactive (inflamație) la două femei de 34 şi 36 ani, la o femeie de 32 ani a fost evidențiat ASC-US (*Atypical Squamous Cells of Undetermined Significance*), atipii ale celulelor pavimentoase intermediare, iar la o femeie de 41 ani NILM, inflamație, foarte numeroase hematii. În celelalte cinci cazuri investigate prin examen citologic (patru din mediul urban şi unul din rural) au fost identificate: HPV tipul 16 la o femeie de 41 ani (care prezenta ASC-US) şi respectiv la o femeie de 23 ani (care prezenta ASC-H: *Atypical Squamous Cells "cannot exclude high-grade squamous intraepithelial lesion* (HSIL)", plus *Gardnerella vaginalis*), precum şi tipul 31 (asociat cu NILM, inflamație, la o femeie de 22 ani), tipul 6 (asociat cu tipul 31 la o femeie de 22 ani care prezenta NILM, inflamație marcată, numeroase hematii), precum şi tipul 58 (la o femeie de 63 ani din mediul rural cu NILM, atrofie, inflamație).

Din cele 182 de testări, 99 (54,4%) cazuri au fost pozitive pentru HPV, 53 (53,5%) fiind infecții unice şi 46 (46,5%) infecții multiple, detectate predominant în mediul urban (94 cazuri: 50 de infecții unice şi 44 de infecții multple). Numărul de testări la femeile din mediul rural a fost foarte mic (şapte cazuri): trei cazuri cu infecții unice cu HPV, două cazuri cu infecții multiple şi două cazuri fără HPV. Au fost identificate 32 tipuri de HPV: 15 tipuri cu risc crescut (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, 73, 82), 14 tipuri cu risc scăzut (6, 11, 42, 54, 55, 61, 62, 70, 72, 74, 81, 83, 84, CP6108) şi 3 tipuri cu risc probabil crescut (26, 53, 66). Grupul filogenetic $\alpha 9$ este implicat în 64 cazuri cu HPV, $\alpha 3$ în 25 cazuri şi $\alpha 10$ în 24 cazuri.

Din cele 94 de infecții cu HPV detectate prin PCR *în mediul urban, 50 de infecții au fost unice* cauzate fiecare de un singur tip de HPV: 30 de infecții cauzate de HPV cu risc crescut (16, 52, 31, 33, 58, 45, 18, 82, 51, 56), 14 infecții produse de HPV cu risc scăzut (42, 6, 55, 70, 62, 83, 84, 81, CP6108), 4 infecții cu HPV 66 cu risc probabil crescut; pentru 2 infecții nu s-a putut preciza tipul de HPV. *În mediul rural* au fost detectate 5 cazuri cu HPV, din care 3 cazuri cu *infecții unice* (detectate în anul 2010: HPV tipul 51 la o pacientă de 39 ani, tipul 58 la o pacientă de 63 de ani şi tipul 84 la o pacientă de 24 de ani).

Din cele *46 de infecții multiple* cu HPV, *44 de cazuri* identificate *în mediul urban* au diverse asocieri de tipuri de HPV: 6 tipuri (1 caz la 36 ani cu tipurile 16, 26, 39, 42, 51, 59), 5 tipuri (4 cazuri; dintre HPV cu risc crescut, predomină tipurile 73, 31, 33), 4 tipuri (7 cazuri; dintre HPV cu risc crescut predomină tipurile 52, 31) sau 3 tipuri de HPV (8 cazuri; HPV cu risc crescut predominate sunt 52, 51, 16, 73), 2 tipuri de HPV (24 cazuri; predomină tipurile 16, 52 dintre HPV cu risc crescut). De la pacientele tinere au fost depistate în mediul urban asocieri de 5 tipuri de HPV la vârsta de 19, 21, 22, 23 de ani şi respectiv de 4 tipuri la vârsta de 20, 24, 26, 27 de ani. În mediul urban, au fost izolate tipurile 35, 39, 59, 68, 73 de HPV cu risc crescut, numai din infecții multiple.

Infecțiile multiple cu HPV detectate *în mediul rural* în anul 2010 au fost produse de tipul 16 asociat cu tipul 61 la o pacientă de 23 de ani şi de tipul 18 asociat cu CP 6108 la o pacientă de 20 de ani. În mediul rural nu s-au constatat infecții multiple cu trei sau mai mult de trei HPV asociate. Nu au fost depistate HPV care să fie prezente numai în mediul rural şi să nu fie depistate în mediul urban.

Numărul de infecţii cu HPV detectate a fost: două sub 20 ani (la 16 şi 19 ani), 55 între 20-30 de ani, 25 între 30-40 de ani, 15 între 40-50 de ani, 1 între 50-60 de ani, 1 > 60 de ani. Intervalul de vârstă cel mai frecvent afectat a fost cel cuprins între 20 şi 25 de ani (42 de cazuri pozitive = 42,4%; 10 cazuri la vârsta de 22 de ani şi numai în mediul urban). La 16-20 de ani au fost detectate doar 9 (9%) infecţii (2 unice şi 7 multiple). Tipurile de HPV frecvent implicate, mai ales în infecţii multiple, între 20 şi 30 de ani, se observă în tabelul I.

Numărul de virusuri izolate pe intervale de vârstă este prezentat în figura 1. În corelaţia dintre numărul de virusuri şi vârstă, coeficientul de corelaţie Spearman r = -0,34 şi p = 0,000002 (figura 1).

TABELUL I.

Tipuri de HPV identificate

Riscul HPV izolate de la cele 182 paciente	Tipuri de HPV izolate	Cazuri cu tipul de HPV izolat		Număr de cazuri cu HPV izolat între 20 şi 30 de ani
		Număr	Procent (%)	
HPV cu risc crescut	16 (α9)	25	13,7	16
	52 (α9)	16	8,7	10
	31 (α9)	11	6	8
	51 (α5)	10	5,4	6
HPV cu risc scăzut	6 (α10)	16	8,7	11
HPV cu risc probabil crescut	66 (α6)	10	5,4	7
	53 (α6)	9	4,9	4

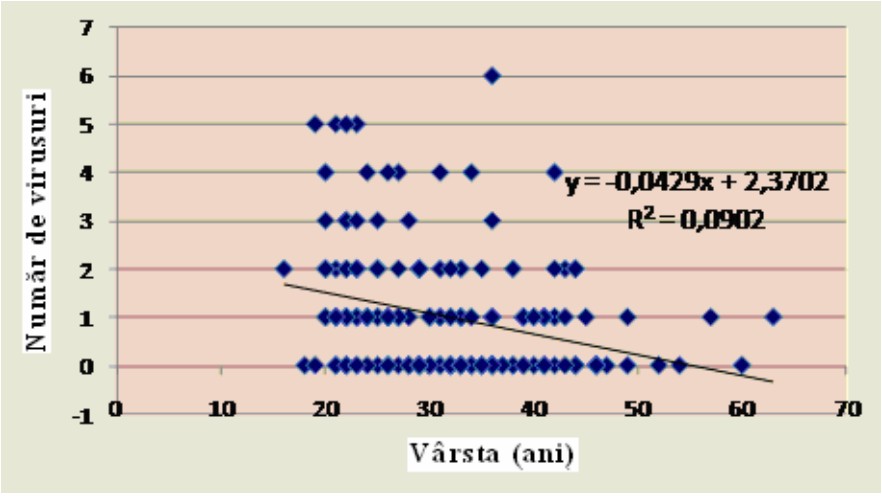

Fig. 1. Corelaţia dintre numărul de virusuri şi vârstă

La cele 182 de femei, media vârstei a fost de 31,84 de ani. Media vârstei este crescută semnificativ la femeile fără infecţie cu HPV (p = 0,00007) comparativ cu cele care au infecţie, dar este scăzută semnificativ la femeile cu infecţie multiplă comparativ cu cele care au infecţie unică şi comparativ cu cele fără infecţie (fig. 2).

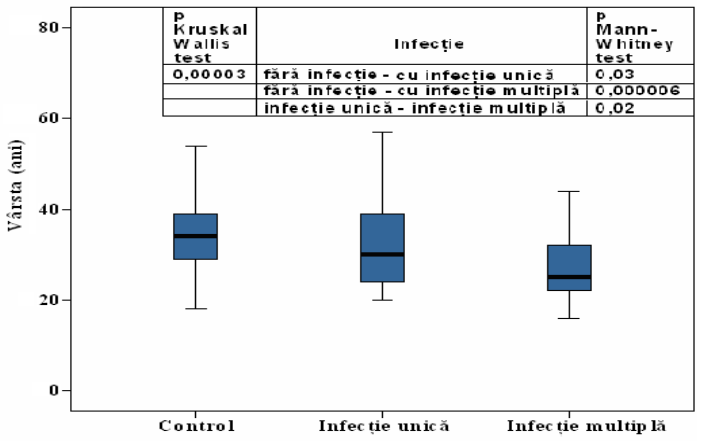

Fig. 2. Tipul de infecție pe intervale de vârstă

Se constată scăderea frecvenței infecției cu HPV odată cu înaintarea în vârstă. Scade frecvența HPV cu risc crescut odată cu înaintarea în vârstă, aspect observat mai ales la tipurile 16, 52, 31, 51, care – comparativ cu celelalte HPV cu risc crescut – sunt izolate în număr mai mare, din infecții unice şi multiple, în mediul urban, frecvent între 20-30 de ani.

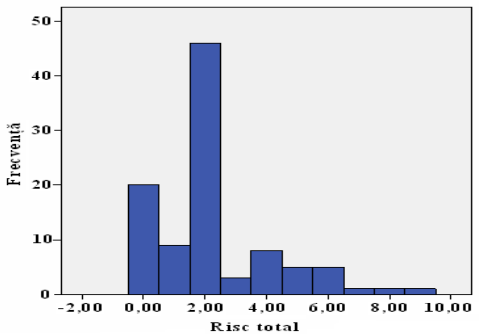

Fig. 3. Corelația dintre vârstă şi riscul total

Pentru a calcula **riscul total** se consideră: riscul scăzut (S) = 0, probabil crescut (PC) = 1 şi crescut (C) = 2 şi apoi se adună (se adună riscurile HPV din fiecare infecție multiplă). Corelând vârsta cu riscul total, coeficientul de corelație Spearman r = -0,26, p = 0,0005. Rezultă că există o corelație semnificativă între vârstă şi riscul total. Cu cât creşte vârsta, cu atât scade riscul total (fig. 3):

DISCUȚII

Pozitivitatea testărilor pentru HPV şi proporția infecțiilor unice şi multiple concordă cu alte cercetări din diverse zone ale lumii (11, 12, 13, 14, 15, 16). Tipul 16 de HPV cu risc crescut a fost cel mai frecvent depistat, prevalența mare a cazurilor din care se izolează acesta fiind semnalată şi de alți autori (13, 14, 15, 17, 18, 19, 20, 21). La fel ca şi în alte studii (18, 19, 20, 22), HPV 16 a fost implicat în infecții unice şi multiple, fiind izolat predominant între 20 şi 30 ani, din infecții multiple, în mediile urban şi rural, iar prevalența tipului 52 a fost de asemenea remarcată după tipul 16 (23,24).

Valori similare cu cea obținută pentru media vârstei celor 182 de paciente testate au fost constatate şi în alte cercetări (11, 25, 26), intervalul de vârstă cel mai frecvent afectat de infecția cu HPV fiind între 20 şi 25 de ani (10 cazuri la vârsta de 22 de ani, numai în mediul urban), aşa cum reiese şi din alte studii (27, 28). Scăderea semnificativă a mediei vârstei la femeile care prezintă infecție cu HPV față de cele fără

infecție, a fost evidențiată şi de alți autori (29, 30), chiar dacă unii nu găsesc o astfel de scădere semnificativă (31). S-a constatat scăderea frecvenței infecției cu HPV odată cu înaintarea în vârstă, la fel ca şi în alte determinări (19, 23, 32), mai ales scăderea cu vârsta a frecvenței infecției cu HPV cu risc crescut (13, 17, 20). Există studii care evidențiază o corelație pozitivă semnificativă a prevalenței HPV cu vârsta (33) sau care arată că prevalența HPV a fost foarte crescută la toate grupele de vârstă, fiind de 54,4% la 18-20 de ani (34) față de 9% în studiul prezent la 16-20 de ani. Şi alte cercetări (16, 17) arată că infecția cu HPV la femeile tinere este mai frecventă şi adesea sunt depistate mai multe tipuri de HPV asociate, aşa cum am constat şi noi (asocieri de 5 sau 4 tipuri, între 20 şi 30 de ani, în mediul urban). În mod cert şi semnificativ, frecvența mare a infecțiilor cu serotipuri multiple de HPV la populația feminină de vârstă tânără din mediul urban semnifică procese comportamentale simultane în cerc vicios: activitatea sexuală începută de la vârstă tânără, în paralel cu lipsa atât a unui program sistematic de educație sexuală oferit de la vârsta şcolară, cât şi a accesibilității la vaccinarea HPV oportună. Fără a fi vorba neapărat de prostituție, ITS denotă nu numai un nivel educativ şi comportamental deficitar, ci sunt markerul epidemiologic de alarmă pentru o populație confruntată cu carențe educaționale în context economic precar şi fără asistență familială şi medicală adecvate (35).

Chiar dacă în această lucrare examenul citologic Babeş-Papanicolaou a fost efectuat numai în 9 cazuri, în 5 cazuri au fost detectate HPV 16, 31, 58 cu risc crescut şi HPV 6 cu risc scăzut, unii autori (36) demonstrând că tipurile 16, 31, 33 sunt asociate cu un examen citologic cu anormalitate. Datele din literatură arată că sensibilitatea şi specificitatea screeningului de cancer cervical creşte prin combinarea citologiei cu hibridizarea (37), iar genotiparea HPV permite o clasificare mai bună a femeilor cu anormalități cervicale în diferite grupe de risc şi poate fi utilă în tratament (38). Se impune o aprofundare a acestui aspect.

CONCLUZII

Nu se cunoaşte suficient statusul infecției cu HPV la populația feminină activă sexual din mediul rural.

Frecvența mai mare a infecției cu HPV (unică sau multiplă) la vârsta tânără trădează lipsa educației sexuale la această grupă de populație şi a impactului ei asupra comportamentului sexual – mai probabil unul promiscuu.

Circulația tulpinilor HPV oncogene impune programul de imunoprofilaxie specifică prin vaccinare HPV.

Carențele de depistare a infecției cu HPV şi a entităților clinice specifice, mai ales în mediul rural, precum şi a accesibilității la imunizarea anti-HPV, au cel mai probabil motivație financiară, ceea ce trebuie să alarmeze decidenții din sistemul sanitar.

NEWS ON PREVALENCE OF VICIOUS HABITS IN CHILDREN (Abstract): **Aim:** The purpose of this study was to determine the prevalence of oral habits among children according to sex and location. **Material and methods:** This study was conducted on 416 children aged 6-11 years old. The children were selected from urban and rural schools of Bacau and Iasi, Romania. Sex and location differences were calculated by using Fisher's exact test. **Results :** The results showed that the prevalence of oral habits was 38,70%; girls (61,5%) were more affected than boys and also the children from urban schools 65,8%. Mouth breathing was the commenest habit (59,5%), followed by thumb thrust (21,5%) and finger sucking (14,1%). The presence or absence of a habit was recording by interview and clinical examination. **Conclusions:** The prevalence of vicious habits in children in our study was 38.70% - representative of the population prevalence of children aged 6-11 years in Romania **Key words:** ORAL HABITS, MOUTH BREATHING, DIGIT SUCKING

Aparatul dentomaxilar îndeplineşte funcţii esenţiale vieţii, în modul acesta se formează, se modelează şi se definitivează, în procesul complex al creşterii şi dezvoltării masivul maxilo- facial. Funcţiile principale ale aparatului dento-maxilar (respiraţia, masticaţia, deglutiţia, fonaţia) sunt asigurate prin mişcările ritmice ale mandibulei, limbii, buzelor, muşchilor mimicii, deprinse în cursul ontogenezei şi coordonate neuro-muscular şi în parte automatizate. Aceste funcţii la rândul lor stimulează dezvoltarea normală a maxilarelor şi modelează forma lor în vederea adaptării la condiţiile de mediu. Mişcările rezultate din funcţionalitatea aparatului dento-maxilar condiţionează în mod egal poziţia dinţiilor (1). Se consideră că direcţia de creştere a arcadelor dentare şi apofizelor alveolare se face într-un culoar muscular din care forţele izvorâte din acţiunea celor două grupuri musculare antagoniste (muşchii jugali şi muşchii orbiculari ai buzelor, situaţi extraoral şi muşchii limbii, situaţi intraoral), se echilibrează. Modificarea ritmului, secvenţei şi intensităţii contracţiei unor fascicule musculare în timpul exercitării funcţiilor aparatului dento-maxilar, creează un dezechilibru funcţional cu interferarea dezvoltării arcadelor dento-alveolare cu apariţia unor rezultante spre vestibular sau oral faţă de această linie a arcadelor. Respiraţia orală, tulburările masticatorii, deglutiţia atipică şi celelalte tulburări funcţionale sunt conside-

rate obiceiuri vicioase. Activităţi reflexe condiţionate patologice, generate şi întreţinute de cauze externe ce se exercită pe un teren dezechilibrat ereditar sau câştigat în cursul vieţii, obiceiurile vicioase sunt acte, gesturi însuşite spontan de subiect, practicate în mod consecvent, uneori pe o durată îndelungată a existenţei, cu o anumită frecvenţă, ritmicitate şi intensitate şi care, în perioada dezvoltării aparatului dento-maxilar – în special în corelaţie cu alţi factori pot genera sau agrava anomaliile dento-maxilare (2,3). Apariţia lor are loc la naştere, evoluând lent pe durata copilăriei, se menţin pe durate foarte variabile, dispărând în scurt timp sau persistând până la 16 ani, chiar mai mult iar când intervine voinţa, dispariţia lor se produce în mod conştient.

MATERIAL ŞI METODE

Studiul de faţă reprezintă o parte dintr-unul mai larg cu privire la modificările sistemului stomatognat, consecinţă a prezenţei obiceiurilor vicioase la copil. Studiul s-a realizat în judeţul Iaşi şi Bacău, incluzând un lot de 416 copii cu vârste de 6-11 ani, de ambele sexe, din mediul urban şi rural. Datele asupra subiecţilor au fost înregistrate de 3 examinatori, special instruiţi cu privire la culegerea datelor. Prezenţa sau absenţa obiceiului vicios s-a înregistrat prin anamneză şi examen clinic. Codurile folosite au fost: 1 - fără obicei vicios; 2 - respiraţie orală; 3 - deglutiţie atipică; 4 - sugerea degetului; 5 - alt obicei vicios. Pentru analiza informaţiilor s-a realizat un program de înregistrări în baza de date SQL, Microsoft Office Excel. S-a stabilit semnificaţia statistică pentru obiceiurile vicioase în relaţie cu sexul, (tab. I, fig. 1) mediul de proveniență (tab. II, fig. 2) şi de importanţa lor (tab. III., fig. 3).

Sugerea degetului	29	14.1
Alt obicei vicios	10	4.9
Total	**205**	**100**

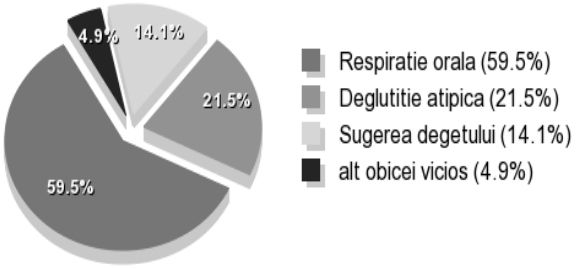

Fig. 3. Prevalența cazurilor cu obiceiuri vicioase

REZULTATE ŞI DISCUȚII

Valorile prevalenței cazueilor cu obiceiuri vicioase la copiii incluşi în studiul nostru au fost de 38,70% fiind reprezentative pentru copiii cu vârste între 6-11 ani din România (tab. IV). Astfel lotul de studiu a fost alcătuit din 161 de subiecți, fete şi băieți, ce prezentau unul sau mai multe obiceiuri vicioase. Fetele, atât din mediul urban cât şi rural au fost mai afectate decât băieții (tab. V). Obiceiul de a respira pe cale orală a fost cel mai frecvent întâlnit, atât în mediul rural cât şi urban. Respirația orală şi deglutiția atipică au fost semnalate mai frecvent la fete, sugerea degetului neavând o diferență semnificativă din punctul de vedere al sexului (tab. VI).

Rezultatele cercetărilor noastre sunt similare altor studii, realizate în Romania şi alte arii geografice (2,5,6). Unii autori (5,7) au constatat valori de prevalențe mai mari la băieți decât la fete în ceea ce priveşte respirația orală. Obiceiurile vicioase, găsindu-le în etiologia anomaliilor dento-maxilare într-o proporție foarte ridicată (54,5%), putem spune, deci, că sunt un factor important în producerea acestora. Combaterea lor poate determina o scădere de 30-40% a anomaliilor dento-maxilare. Obiceiurile vicioase rup echilibrul muscular şi tulbură creşterea oaselor, dând o nouă direcție de creştere acestora, în sensul tracțiunii şi presiunii, producând modificări de poziție a dinților, arcadelor şi oaselor maxilare. Acestea sunt însoțite însă, şi de tulburări fizionomice, cu consecințe în dezvoltarea psiho-intelectuală, creând copilului un complex de inferioritate, ce duce la schimbarea comportării în colectivitate (5, 6, 7).

TABELUL IV

Prevalenţa cazurilor cu obiceiuri vicioase în relaţie cu sexul

Total cazuri				Repartiţia pe sex							
Examinate		Cu obiceiuri vicioase		Examinate				Cu obiceiuri vicioase			
Nr.	%	Nr.	%	M		F		M		F	
				Nr.	%	Nr.	%	Nr.	%	Nr.	%
416	100	161	38,70	177	42,5	239	57,5	62	38,5	99	61,5

Prevalenţa cazurilor cu obiceiuri vicioase repartizate pe sex şi mediul de proveniență

Subiecţi cu obiceiuri vicioase	Masculin		Feminin	
	Nr.	%	Nr.	%
Urban	38	35,8	68	64,2
Rural	24	43,6	31	56,4

TABELUL VI

Distribuţia pe sex a cazurilor cu obiceiuri vicioase

Obicei vicios	Masculin		Feminin	
	Nr.	%	Nr.	%
Respiraţie orală	49	40,2	73	59,8
Deglutiţie atipică	11	25	33	75
Sugerea degetului	14	48.3	15	51,7
Alt obicei vicios	6	60	4	40

CONCLUZII

Cercetările noastre au evidenţiat faptul că prevalenţa obiceiurilor vicioase la copii din lotul de studiu a fost de 38,70%, fiind reprezentativă pentru populaţia cu vârste între 6-11 ani din România. Fetele, atât din mediul urban cât şi din cel rural au fost mai afectate decât băieţii iar frecvenţa respiraţiei orale s-a situat pe primul loc între obiceiurile vicioase, atât în mediul rural cât şi urban. Respiraţia orală şi deglutiţia atipică au fost înregistrate mai frecvent la fete dar sugerea degetului nu a prezentat o diferenţă semnificativă a repartiţiei pe sex.

STUDY ABOUT THE ASSOCIATED USE OF DIFFERENT TYPES OF DRUGS BY HIGH SCHOOL STUDENTS (Abstract): Socially acceptable drugs and illegal substances consumed by high school students affect their nervous system, which is under development and anticipate an extensive drug use later. **Material and method**: In our study we have assessed the associate drug consumption at a group of high school teenagers by applying a questionnaire with 23 items. **Results and discussion:** Tobacco use is the lowest in ninth grade students and it is significantly better represented in higher grade students. Regardless of the grade, there are no significant differences in the proportion of boys and girls who smoke, even the health risks posed by smoking are known to over 80% of respondents. Among the reasons that could cause the student smoking cessation predominates, at the smallest students, parents' threat (significantly stronger than at those of senior grades), unlike the senior students, which give a higher value to a possible alteration of their own health status. The temptation for beer consumption appears before the age of 11 years and it is mentioned about a quarter of all respondents. Drinking a glass of wine for the first time is placed around the age of 14 years for boys and 15 years for girls. Marijuana is the drug exclusively consumed in the ninth grade and holds supremacy and other classes. Barbiturates and amphetamines are known about two thirds of the surveyed students. Risks involved by the association of alcohol consumption, tobacco and drugs are represented differently in this group of adolescents, and evolve differently as the students grow, mature and evolve, in a positive manner for their existence or not. **Conclusions:** during the high school years teenagers are tempted to diversify their drug consumption and to associate them, even they know very well how serious are the health consequences of this attitude. **Key words:** SMOKING, ALCOHOL, DRUGS, TEEN-AGERS, HIGH SCHOOL

Drogurile licite sau acceptate social (tutunul sau alcoolul) sau cele ilicite (substanţe sedative, stimulante, narcotice sau halucinogene) consumate de către elevii de liceu le afectează sistemul nervos, care este în proces de dezvoltare, şi anticipează o utilizare extensivă a drogurilor mai târziu (1, 2, 3).

Stilul de viaţă ce implică un consum regulat de droguri include nonconformismul faţă de valorile tradiţionale, trăsătură întâlnită în rândul majorităţii adolescenţilor din

ziua de azi. Relaţiile familiale dificile, lipsa intereselor educaţionale sau stările de alienare şi revoltă, precum şi experienţele emoţionale negative sunt factori ce determină consumul de droguri în rândul adolescenţilor (2, 3).

Studiile realizate până în prezent nu indică un anumit tip de personalitate asociat cu consumul de droguri. Adolescenţi sunt tentaţi să încerce drogurile dintr-o multitudine de motive, cum ar fi curiozitatea, dorinţa de a trăi o altă stare de conştiinţă, de a se integra într-un nou grup, de a evita durerea fizică sau orice altă problemă gravă, ori, pur şi simplu, pentru a "condimenta" un stil de viaţă devenit plictisitor (4, 5).

OBIECTIVE

În această lucrare ne-am propus să evaluăm comparativ, la diferite vârste (clase de liceu) cum percep elevii adolescenţi drogurile, atât cele acceptate social (tutunul şi alcoolul) cât şi substanţele psihotrope ilicite, dacă le consumă, pe care le consumă şi cu ce frecvenţă, cum le asociază, respectiv dacă sunt conştienţi de riscurile care le incumbă consumul pentru sănătatea lor.

MATERIAL ŞI METODĂ

În realizarea studiului am elaborat şi aplicat un chestionar cu 23 de itemi unui număr de 200 de elevi dintr-un liceu din zona urbană II (adolescenţi cu vârste cuprinse între 15 şi 19 ani, înmatriculaţi în clasele a IX-a, a X-a, a XI-a şi a XII-a).

Din fiecare an de studiu au fost selectate aleatoriu la începutul semestrului II din anul şcolar 2009-2010 câte două clase, însumând 50 de elevi, care au răspuns întrebărilor din chestionar în cadrul orelor de dirigenţie, în prezenţa unor persoane calificate.

Datele obţinute (care au un caracter strict de confidenţialitate, pentru a creşte acurateţea analizei) au fost prelucrate statistic utilizând programului *EpiInfo 3.5.1*, prin analiză univariată, folosind indicatorii statistici descriptivi.

Pentru determinarea semnificaţiei statistice între diferite frecvenţe au fost aplicate variantele testului χ^2 *Mantel-Haenszel* şi *Yates* (formula corectată).

REZULTATE ŞI DISCUŢII

Subiecţii incluşi în studiu sunt predominant băieţi comparativ cu fetele (la nivelul întregului lot raportul M:F fiind de 1,70:1). Cei mai mulţi dintre elevii incluşi în studiu (59%) provin din mediul rural şi doar 41% provin din mediul urban, cu o dezvoltare staturo-ponderală în limitele normale pentru vârsta lor (normoponderali, dezvoltaţi armonic).

Consumul de tutun

Consumul de tutun, sau fumatul, este cel mai redus la elevii de clasa a IX-a şi este semnificativ mai bine reprezentat în clasele a X-a (χ^2=4,54 şi p=0,0329), a XI-a (χ^2=6,3529 şi p=0,00117) şi a XII-a (χ^2=14,77 şi p=0,0001).

Indiferent de clasa în care se află 55% dintre elevi au fumat prima ţigară înainte de 15 ani (momentul intrării la liceu), respectiv sunt diferenţe semnificative între proporţia băieţilor şi cea a fetelor care fumează.

Dintre elevii chestionaţi, 16% dintre cei din clasa a IX-a fumează zilnic, respectiv sunt semnificativ mai mulţi cei care au acelaşi obicei, dar sunt în clasa a XI-a (χ^2=7,071 şi p=0,007) respectiv în clasa a XII-a (χ^2=20,33 şi p=0,000006).

În ceea ce priveşte motivaţia fumatului 32% dintre toţi elevii este, indiferent de clasă, menţionează curiozitatea sau lipsa unui motiv anume.

Referitor la riscurile pe care le presupune fumatul peste 80% dintre cei chestionaţi, indiferent de clasă, ştiu că duce la schimbarea aspectului/culorii dinţilor şi la diferite forme de cancer (laringian, esofagian, pulmonar).

Motivaţia care ar determina renunţarea la fumat, prezentată în figura 1, dobândeşte alte valenţe în timp, pe măsură ce adolescentul se maturizează. Astfel, dacă la elevul de clasa a IX-a ameninţarea părinţilor este semnificativ mai puternică (χ^2=7,04 şi p=0,0079) decât la cei de clasa a XI-a şi a XII-a, posibila alterare a propriei stări de sănătate este semnificativ mai importantă pentru cei din clasele mari (a XI-a şi a XII-a) (χ^2=6,35 şi p=0,001 respectiv χ^2=5,26 şi p=0,0217). De remarcat că preţul de cost al ţigărilor nu este un motiv de renunţare la acest obicei suficient de percutant la nici o vârstă.

Majoritatea elevilor chestionaţi asupra fumatului (între 88 şi 96%, cu o medie de 91,5%) admit că fumatul nu are nici un beneficiu real pentru consumatorul adolescent.

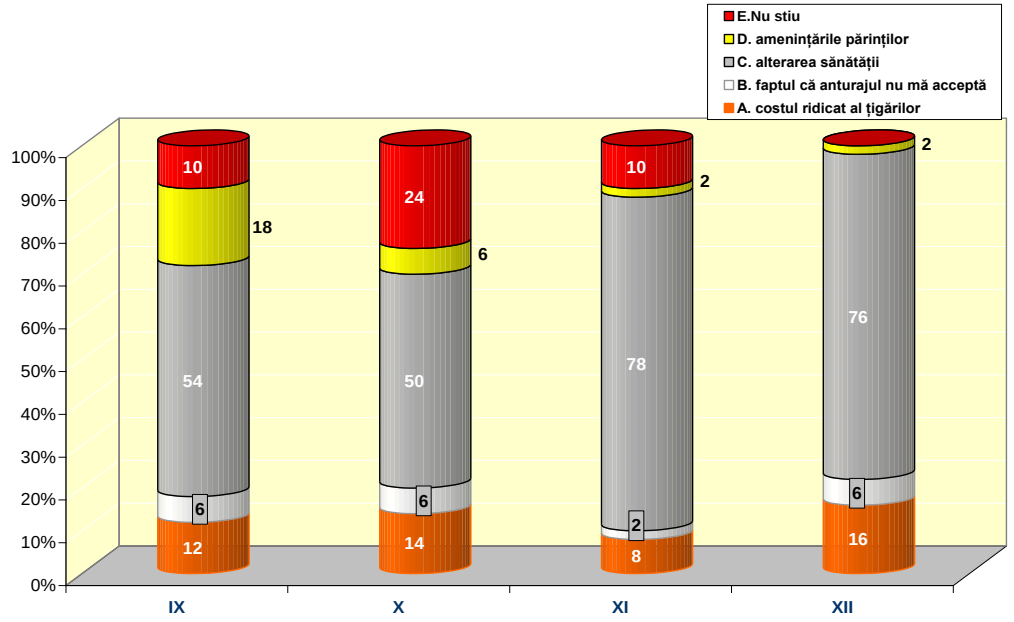

Fig. 1. Ce i-ar putea determina pe elevii de liceu să renunţe la fumat ?

Consumul de alcool

Dintre băuturile alcoolice preferate de către adolescenţi se remarcă berea. Astfel, 71,5% dintre toţi elevii incluşi în studiu au consumat maximum de două ori bere în ultima lună, fără să existe diferenţe între o clasă sau alta. Abuzul de bere este apanajul băieţilor, fără deosebiri legate de vârsta consumatorului.

O situaţie similară întâlnim şi în cazul vinului unde 72,5% dintre elevi au consumat de maximum două ori vin în ultima lună. Un aspect interesant este acela că toate fetele chestionate nu au consumat vin de mai mult de 5 ori în ultimele 30 de zile.

În ceea ce priveşte băuturile spirtoase se remarcă un aspect comun celor chestionaţi şi anume acela că 64,5% nu au consumat deloc astfel de băuturi în ultima lună şi doar 20% le-au consumat de 1-2 ori.

O consecinţă imediată dar şi cu posibile efecte pe termen mediu şi lung este starea de ebrietate. Cu cât aria de căutare este mai mare cu atât răspunsurile sunt mai puţin exacte, cele mai exacte (sincere) fiind răspunsurile elevilor din clasa a IX-a.

Un alt detaliu legat de consumul de băuturi alcoolice este „vârsta primului pahar". Analizând acest moment, dar în conexiune cu tăria alcoolică a băuturii (grade de alcool pur), putem remarca pentru bere tentaţia consumului precoce înainte de 11 ani la aproximativ un sfert dintre toţi cei chestionaţi.

Dacă la cei din clasele mediane nu sunt diferenţe între băieţi şi fete, la clasele extreme băieţii care au consumat bere înainte de 11 ani sunt de 2, respectiv de 12 ori, mai numeroşi comparativ cu fetele.

Consumul unui pahar de vin pentru prima dată mută accentul spre 14 ani la băieţi şi spre 15 ani la fete.

Băuturile spirtoase nu au fost (cel puţin declarativ) consumate de 48, 44, respectiv 30% dintre elevii cei mai mici şi doar de 14% dintre elevii mari ($\chi 2=13,37$ şi $p=0,0002$).

Băuturile alcoolice dulci nu au fost consumate de 40% dintre elevii cei mai mici şi doar de 14% dintre elevii mari ($\chi^2=8,48$ şi $p=0,003$).

Ultimul aspect analizat de chestionarul nostru privind consumul de alcool a fost „vârsta primei beţii". Proporţia celor care neagă că ar fi ajuns la starea de ebrietate scade, pe măsură ce cresc, de la 20% la 12% pentru băieţi şi de la 26% la 16% pentru fete. Evenimentul este plasat după vârsta de 15 ani pentru cei din clasa a IX-a şi peste 16 ani pentru ceilalţi. Jumătate dintre elevii din anul terminal recunosc că au ajuns în stare de ebrietate, băieţii fiind de 2,5 ori mai mulţi comparativ cu fetele.

Consumul de droguri

Ultima secţiune a chestionarului aplicat celor 200 de adolescenţi a fost dedicată consumului de droguri „ilicite" sau de substanţe psihotrope.

Consumul de droguri este cel mai redus la elevii de clasa a IX-a şi semnificativ mai bine reprezentat în clasele a X-a ($\chi^2=5,019$ şi $p=0,02$), a XI-a ($\chi^2=7,087$ şi $p=0,007$) şi a XII-a ($\chi^2=4,069$ şi $p=0,043$) (Fig. 2).

De asemenea, sunt diferenţe semnificative între proporţia băieţilor şi cea a fetelor care consumă droguri la clasa a X-a (de 3 ori mai mulţi) şi la clasa a XII-a (de 4,5 ori mai mulţi).

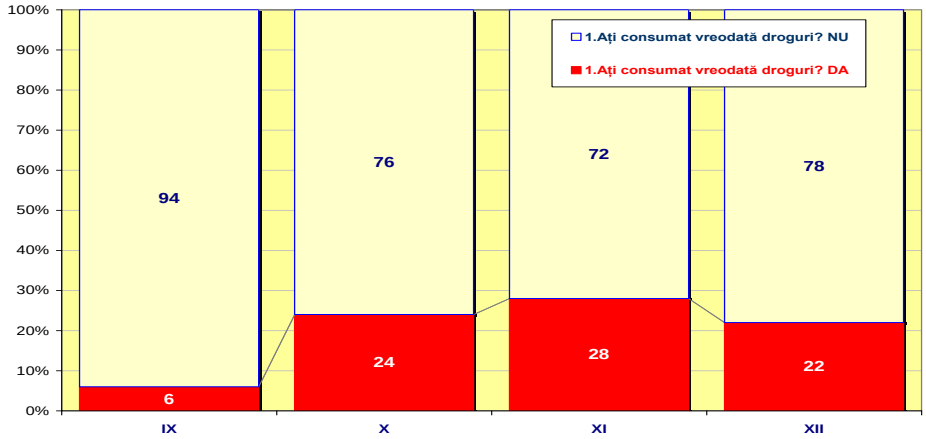

Fig. 2. Distribuţia elevilor din clasele de liceu în funcţie de consumul de droguri

Legat de tipul de drog care este preferat de fiecare clasă în parte, se observă că **marijuana** este drogul exclusiv pentru cei din clasa a IX-a care afirmă că sunt consumatori, dar deține supremația și la consumatorii din celelalte clase: 71,43% la clasa a X-a, 76,92% la clasa a XI-a și 58,34% la clasa a XII-a (Fig. 3).

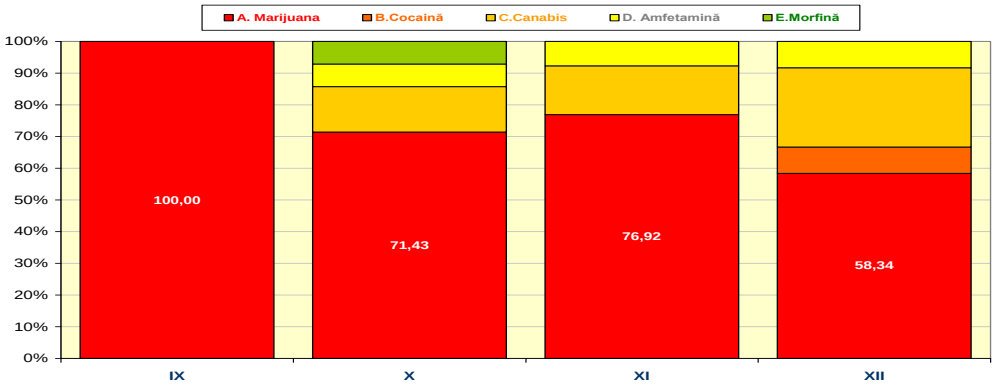

Fig. 3. Distribuția consumului diferitelor droguri în funcție de clasa în care se află elevii chestionați

Frecvența declarată a consumului indică pentru clasa a IX-a *doar o singură încercare* drept predominantă, pe când la clasele mai mari predomină *consumul ocazional*: 58,33% la clasa a X-a, 64,28% la clasa a XI-a și 81,81% la clasa a XII-a.

Motivația primului contact cu substanțele psihotrope și apoi repetarea experienței la cei chestionați constă în special în *generarea unei stări de bine* indiferent de vârstă: la 75% dintre elevii consumatori de clasa a IX-a; la 63,64% dintre elevii consumatori de clasa a X-a; la 92,30% dintre elevii consumatori de clasa a XI-a și la toți elevii consumatori de clasa a XII-a (Fig. 4).

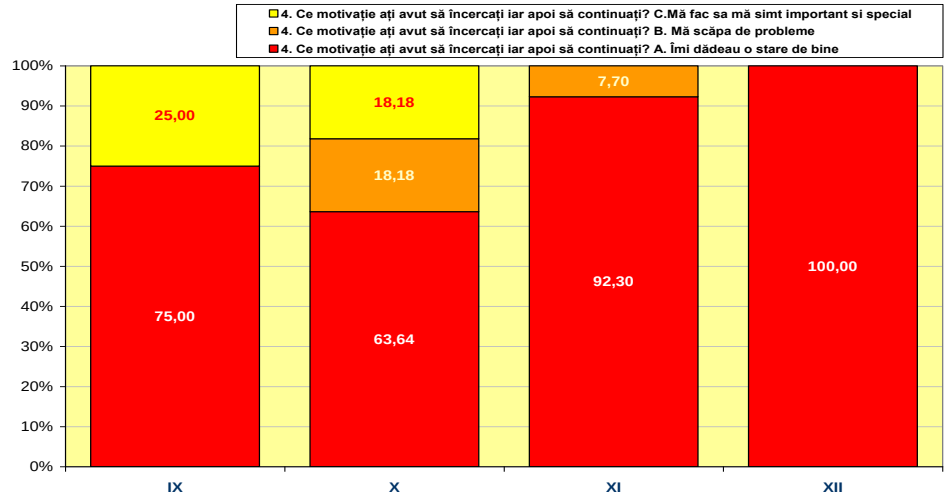

Fig. 4. Motivația consumului de substanțe psihotrope la elevii de liceu chestionați

Un alt detaliu extrem de interesant al investigaţiei noastre a fost reprezentat de nivelul de informare a elevilor din clasele de liceu despre posibilele efecte ale consumului de substanţe psihotrope asupra stării lor de sănătate:

- dependenţa fizică şi psihică este cunoscută de 58% dintre respondenţi, fără diferenţe semnificative între clase;
- tulburările psihice sunt cunoscute de 24,5% dintre respondenţi, fără diferenţe semnificative între clase;
- afectarea memoriei este cunoscută de 17,5% dintre respondenţi, fără diferenţe semnificative între clase;
- afectarea inimii este cunoscută de 13,5% dintre respondenţi, cu diferenţe semnificative între clasa a IX-a şi a X-a (χ^2=5,65 şi p=0,017)

Grila de tip asociativ, care a urmărit să scoată în evidenţă dacă elevii ştiu ce acţiune imediată au diferitele substanţe psihotrope, a fost completată cel mai corect de către elevii din:

- clasa a IX-a pentru amfetamine (70%) şi barbiturice (68%)
- clasa a X-a pentru barbiturice (62%) amfetamine şi marijuana (câte 56%)
- clasa a XI-a pentru barbiturice (64%) şi amfetamine (60%)
- clasa a XII-a pentru barbiturice (76%) şi cocaină (70%)

Acest fapt relevă existenţa unui nivel de informare şi/sau interes peste medie pentru barbiturice (indiferent de clasă), amfetamine (clasele a IX-a - a XI-a) şi cocaină doar la elevii din clasa a XII-a.

Elevii din clasele de liceu privesc diferit posibilitatea renunţării la consumul de droguri. Elevii de clasa a IX-a sunt semnificativ mai puţin convinşi că ar putea renunţa fără ajutor specializat comparativ cu elevii din clasa a X-a (χ^2=6,55 şi p=0,0104), a XI-a (χ^2=9,79 şi p=0,00175) şi a XII-a (χ^2=3,849 şi p=0,0484).

Asocierea riscurilor pe care le reprezintă consumul de alcool, tutun şi droguri este reprezentată diferit în acest grup de adolescenţi şi evoluează în diverse moduri, pe măsură ce elevii cresc şi se maturizează într-un sens pozitiv sau nu pentru existenţa lor viitoare.

Astfel, putem identifica 7 subgrupuri de elevi care consumă cu diferite frecvenţe:

- doar alcool (berea fiind elementul comun pentru toate clasele) (53%);
- alcool şi tutun (27,5%);
- alcool, tutun şi ocazional droguri (9,5%);
- alcool, tutun şi cel puţin o dată au încercat să consume şi droguri (3,5%);
- alcool şi ocazional droguri (3,0%);
- alcool, tutun şi zilnic droguri (2%);
- alcool şi cel puţin o dată au încercat să consume şi droguri (1,5%) (Fig. 5)

Prin aplicarea testului χ^2 am identificat următoarele aspecte:

- sunt semnificativ mai mulţi elevii care consumă doar alcool în clasa a IX-a comparativ cu clasa a XII-a (χ^2=20,19 şi p=0,0000007), tendinţa fiind de reducere a monoconsumului pe măsură ce adolescentul creşte.
- sunt semnificativ mai mulţi elevii care asociază alcoolul cu tutunul în clasa a XII-a comparativ cu clasa a IX-a (χ^2=7,821 şi p=0,0051).

La clasa a XII-a se observă o distribuţie extrem de „variată” comparativ cu clasele mai mici în ceea ce priveşte asocierile de droguri:

- 44% beau şi fumează;
- 36% doar beau;
- 12% beau, fumează şi ocazional se droghează;
- 4,0% beau, fumează şi au încercat cel puţin o dată drogurile;
- 4,0% beau şi ocazional se droghează.

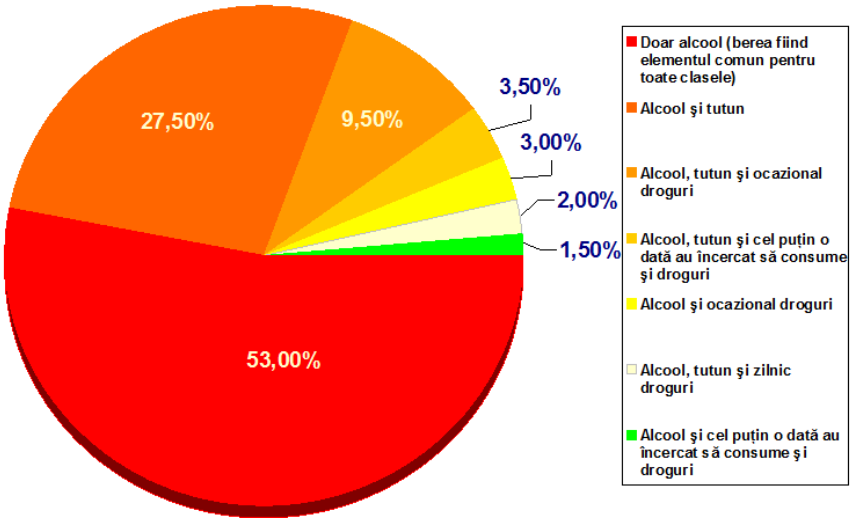

Fig. 5. Asocierea diferitelor tipuri de droguri la cei 200 de elevi chestionaţi

CONCLUZII

Consumul de tutun este cel mai redus la elevii de clasa a IX-a şi este semnificativ mai bine reprezentat la elevii din clasele mai mari.

Nu sunt diferenţe semnificative între proporţia băieţilor şi cea a fetelor care fumează, indiferent de clasă.

La peste o treime din toţi elevii, indiferent de clasă se remarcă pentru consumul de tutun o similitudine motivaţională, şi anume curiozitatea sau absenţa unei motivaţii.

Riscurile pe care le presupune fumatul (schimbarea aspectului/culorii dinţilor şi cel de apariţie a neoplaziei) sunt cunoscute de peste 80% dintre elevii chestionaţi.

Dintre motivele care ar putea determina renunţarea la fumat predomină la elevul de clasa a IX-a ameninţarea părinţilor (semnificativ mai puternică decât la cei de clasa a XI-a şi a XII-a), spre deosebire de elevii mai mari, care valorizează mai mult o posibilă alterare a propriei lor stări de sănătate.

Preţul de cost al ţigărilor nu este un motiv suficient de percutant pentru a determina adolescentul să renunţe la fumat la nici o vârstă, între 14 şi 19 ani.

Majoritatea elevilor chestionaţi asupra fumatului (91,5%) sunt de acord că fumatul nu aduce nici un beneficiu real consumatorului adolescent.

Alcoolul, considerat drogul social cel mai acceptat, este şi preferatul adolescenţilor mai ales dacă vorbim de bere (cea mai agreată) sau de vin şi mai puţin de băuturile spirtoase cu tărie alcoolică peste 40º.

În privinţa debutului consumului de alcool, corelat cu tăria alcoolică a băuturii (grade de alcool pur), putem remarca la aproximativ un sfert dintre toţi cei chestionaţi tentaţia consumului precoce (înainte de 11 ani) de bere.

La clasele extreme băieţii care au consumat bere înainte de 11 ani sunt de două, respectiv de 12 ori, mai numeroşi comparativ cu fetele. Referitor la acest aspect la elevii din clasele a X-a şi a XI-a, între băieţi şi fete nu sunt diferenţe semnificative statistic.

Consumul pentru prima dată al unui pahar de vin este identificat în jurul vârstei de 14 ani la băieţi şi spre 15 ani la fete.

Marijuana este drogul exclusiv folosit de către consumatorii de clasa a IX-a, dar care deţine supremaţia şi la celelalte clase.

Aproximativ 2/3 dintre elevii chestionaţi au informaţii corecte despre ce sunt barbituricele şi amfetaminele şi ce efecte imediate produc consumul lor.

Consecinţele pe termen mediu şi lung cunoscute de cei mai mulţi elevi (58%) sunt dependenţa fizică şi cea psihică.

Asocierea consumului de alcool, tutun şi droguri este un proces dinamic, tendinţa fiind de reducere a monoconsumului pe măsură ce elevii cresc şi se maturizează.

Deşi chestionarul a fost confidenţial se poate observa o nuanţă fină de neîncredere la subiecţii intervievaţi, când se abordează probleme cum ar fi starea de ebrietate şi, mai ales, consumul de droguri ilicite, tentaţia fiind de mistificare a realităţii.

NOUTĂȚI

MANAGEMENTUL CONSERVATOR AL TRAUMATISMELOR CONTUZE HEPATICE: CARE ESTE DURATA OPTIMĂ A SPITALIZĂRII?

Atitudinea terapeutică curentă pentru traumatismele contuze hepatice la pacienţi stabili hemodinamic este non-chirurgicală. Cu toate acestea, durata optimă a spitalizării pentru aceşti pacienţi nu este încă stabilită. Într-un centru de traumatologie la care externarea pacienţilor cu traumatisme contuze hepatice a fost hotărâtă exclusiv pe baza criteriilor clinice au fost analizate retrospectiv registrele de trauma. Datele obţinute au inclus informaţii despre severitatea leziunilor, gradul leziunii hepatice, durata spitalizării, rata de succes a tratamentului conservator şi, acolo unde a fost necesar, motivul modificării atitudinii terapeutice de la conservatoare la chirurgicală. Între 2002 şi 2007, 591 de pacienţi au fost internaţi consecutiv unui traumatism contuz hepatic; în 35 de cazuri atitudinea a fost chirurgicală, în special consecutiv hemoragiei datorate leziunilor organelor vecine. Durata medie de spitalizare pentru restul cazurilor a fost de 2,2 zile. Nu s-au înregistrat consecinţe nefaste consecutiv externării pe baza criteriilor clinice. Concluziile studiului indică utilitatea examinării clinice în evaluarea duratei de spitalizare a traumatismelor contuze hepatice; autorii susţin că acestea ar trebui să fie criteriu unic în condiţiile unui examen abdominal normal la un pacient hemodinamic stabil, indiferent de gravitatea traumatismului. INFLUENCE OF VICIOUS ORAL HABITS IN THE DEVELOPMENT OF DENTO-MAXILLARY SISTEM (Abstract): Main features of the dentomaxillary sistem (breathing, chewing, swallowing) are provided by the rhythmic movements of the mandible, tongue, lips, mimic muscles, learned during ontogenesis and coordinated neuromusculary and largely automated. **Aim:** The aim of our study was to prove the role of oral habits in the development of dentomaxillary anomalies. We made experimental investigations - model studies , fotostatic test for face and side face , radiological examinations, clinical general and ENT exam for accurately assess of the factors which contribute to the emergence and development of dento – maxillary anomalies. **Material and methods:** The study group consisted of 175 children (94 girls and 81 boys) aged between 7 and 14 years. We made individual sheets for recording neuromuscular and oropharyngeal balance starting from a patient's overall clinical appearance. **Results:** The diagnosis of most teenagers was first Angle's class of malocclusion with tongue thrusting and mouth breathing. Oral habits disrupt the muscular balance and bone growth producing changes in the dental arch and occlusal characteristics. The high prevalence of dentomaxillary anomalies (52.57%) and obvious interrelationship with functional imbalances of the dentomaxillary sistem (62.82% of subjects examined) supports the implication of functional factors in those etiology .**Conclusions:** Suppression of vicious habits by methods of awareness, myogymnastic and functional reducing exercises are the first steps of early functional treatment for dentomaxillary anomalies **Key words**: TONGUE THRUSTING, MOUTH BREATHING, ANGLE MALOCCLUSION

Funcţiile principale ale aparatului dento–maxilar (respiraţia, masticaţia, deglutiţia) sunt asigurate prin mişcările ritmice ale mandibulei, limbii, buzelor, muşchilor mimicii, deprinse în cursul ontogenezei şi coordonate neuro – muscular şi în mare parte automatizate.

Aceste funcţii, la rândul lor, stimulează dezvoltarea normală a maxilarelor şi modelează forma lor în vederea adaptării la condiţiile de mediu. Mişcările rezultate din funcţionabilitatea aparatului dento – maxilar condiţionează în mod egal morfologia şi poziţia dinţilor (1)

Se consideră că direcţia de creştere a arcadelor şi apofizelor alveolare se face într-un culoar muscular în care forţele izvorâte din acţiunea celor două grupe musculare antagoniste (muşchii jugali şi orbiculari ai buzelor - extraoral şi de muşchii limbii situaţi intraoral) se echilibrează.

Modificarea ritmului, secvenţei şi intensităţii contracţiei unor fascicule musculare în timpul exercitării funcţiilor aparatului

dento – maxilar creează un dezechilibru funcţional cu afectarea dezvoltării arcadelor alveolo – dentare cu apariţia unor rezultante spre vestibular sau oral faţă de această linie a arcadelor.(2)

Respiraţia orală, tulburările masticatorii, deglutiţia atipică şi celelate tulburări funcţionale sunt considerate obiceiuri vicioase. În afara acestor obiceiuri vicioase provenite din desfaşurarea anormală a unor stereotipe funcţionale, există o grupă aparte de obiceiuri vicioase propriu-zise determinate de exercitarea unor atitudini posturale (dormitul cu capul în poziţii anormale sau compresiunea anormală pe maxilare în diferite faze de activitate) sau de exercitarea unor obiceiuri vicioase (de sugere, muşcare, roadere).

Obiceiurile vicioase rup echilibrul muscular şi tulbură creşterea oaselor, dând o nouă direcţie de creştere a acestora, în sensul tracţiunii şi presiunii, producând modificări de poziţie a dinţilor, arcadelor şi oaselor maxilare.(3)

MATERIAL ŞI METODĂ

Lotul de studiu a fost alcătuit din 175 copii (94 de fete şi 81 de băieţi) cu vârste cuprinse între 7 şi 14 ani.

Pentru evaluarea exactă a factorilor care concură la apariţia şi evoluţia anomaliilor dento – maxilare, după realizarea examenului clinic individual şi punerea unui diagnostic prezumtiv, s-a apelat la o serie de investigaţii experimentale: studii de model, examen fotostatic de faţă şi profil, examene radiologice, examen clinic general şi ORL.

S-au întocmit fişe individuale pentru consemnarea bilanţului neuro – muscular, oro – faringian pornind de la aspectul clinic general al pacientului, modul de desfpşurare a funcţiilor aparatului dento – maxilar, evidenţierea disfuncţiilor şi obiceiurilor vicioase, continuând cu examenul musculaturii jugale, buzelor şi limbii.

Distribuţia subiecţilor cu anomalii dento – maxilare şi obiceiuri vicioase, precum şi interpretarea şi raportarea datelor s-au facut pe clase de vârstă şi sex. Ţinânad cont de multitudinea de forme clinice de anomalii dento – maxilare şi de tipuri de clasificare, pentru studiul nostru am folosit clasificarea ocluzionistă Angle, clasificare curent utilizată de şcolile de ortodonţie în cercetare şi practică.

REZULTATE ŞI DISCUŢII

Din analiza statusului anomaliilor dento – maxilare rezultă că jumatate din populaţia examinată (52,57%) prezintă anomalii, din care; 41,14% malocluzii Clasa I Angle; la diferenţă de aproximativ 30 de procente; 5,14% subiecţi cu malocluzii Clasa II_1 şi 6,28% subiecţi cu malocluzii Clasa II_2.

Analiza pe clase de sex şi vârstă arată un procentaj mai mare de fete cu anomalii decât de baieţi la toate grupele de vârstă cu excepţia ultimei grupe (12 – 13 ani). Repartiţia subiecţilor pe clase de anomalii arată o situaţie inversă, cu valori mai mari la băieţi decât la fete în majoritatea grupelor de vârstă pentru anomaliile de Clasa I Angle şi primele două grupe de vârstă pentru Clasa II_2 Angle. Procentajul de subiecţi afectaţi de una sau mai multe obiceiuri vicioase se situează la valori medii foarte ridicate (62,85%) din care 47,42% sunt la originea malocluziilor Clasa I Angle si 15,42% a malocluziilor Clasa II_1 Angle (tab. I).

Analiza tipurilor de obiceiuri vicioase arată o pondere a subiecţilor cu deglutiţie atipică (45,14%) şi la fete (57,44% fete faţă de 30,86% la băieţi) urmată la diferentă de 30 de procente de subiecţi cu respiraţie orală (16,57%) la valori apropiate fete şi băieţi (fig. 1,2,3).

TABELUL I

Distribuția subiecților după tipurile de obiceiuri vicioase pe grupe de vârstă, sex şi clase de anomalii Angle

		Clasa Angle		Clasa I	Clasa II_1		$I + II_1$

	B	0	0							
	T	8.10	27.02	0	0	0				
Total	F	10.63	35.10	2.12	6.38	22.34	17.02	57.44	2.12	76.59
	B	16.04	30.86	0	0	0	16.04	30.86	0	46.91
	T	13.14	33.14	1.14	3.42	12	16.57	45.14	1.4	62.85
		47.42%		**15.42**						

Fig. 1. Deglutiție atipică

Fig. 2. Deglutiție atipică

Fig. 3. Respirator oral

Fig. 4. Obicei vicios de muşcare a buzei inferioare

Cele mai mari valori se inregistrează la clasa de vârstă 8 – 9 ani când, alături de cele două disfuncţii enunţate se evidenţiază şi obiceiul vicios de muşcare a buzei inferioare. (fig. 4)

Distribuţia tipurilor de disfuncţii pe clasă de anomalie şi grupă de vârstă arată că doar doua grupe de vârstă (9 – 10 ani şi 10 – 11 ani) se înscriu în Clasa I şi II1 Angle, celelalte înscriindu-se în Clasa I Angle.

După cum afirmă Moss, mişcările rezultate din funcţionalitatea aparatului dento – maxilar condiţionează în mod egal morfologia maxilarelor şi poziţia dinţilor.Cum zona incisivă este cea mai vulnerabilă la acţiunea factorilor disfuncţionali, ea pune în evidenţă primele semne de anomalie în pierderea echilibrului muscular endobucal şi exobucal. Este influenţată direcţia de implantare a dinţilor şi de creştere a proceselor alveolare, ele fiind deviate sagital (grade diferite de inocluzie sau proalveolodenţie sau/şi vertical (supraocluzie sau inocluzie verticală)

Distribuţia subiecţilor afectaţi după modificarea zonei frontale (semne clinice) arată o pondere a modificărilor sagitale exprimate prin gradul de inocluzie: 43,42% subiecţi cu overjet redus (2 – 4 mm), 8% subiecţi cu overjet mediu (4 – 6 mm) şi 1,71 % subiecţi cu overjet mai mare de 6 mm. (tab. II)

TABELUL II

Distribuţia subiecţilor (%) după semne clinice şi tipuri de anomalii

Anomalii dento – maxilare	**Clasa I**			**Clasa II_1**			**Clasa II_2**		
	F	B	T	F	B	T	F	B	T
Overjet 2-4 mm	51.06	23.45	38.3	7.44	2.46	5.14	58.5	25.9	43.42
Overjet 4-6 mm	3.19	9.87	6.28	3.19	0	1.7	6.38	8.87	8
Overjet >6 mm	-	-	-	0	3.7	1.7	3.19	7.4	5.14
Bipro Alveolo denţie	0	3.7	1.7	0	7.4	3.42	3.19	7.4	5.14
Inocluzie verticală	7.44	11.11	9.14	6.38	2.46	4.57	13.8	13.6	13.7

În ordine cronologică inocluzia verticală (13,7%) urmează la diferenţă remarcabilă (de aproximativ 30 de procente) imediat după inocluzia sagitală uşoară.

Încadrarea semnelor clinice în clasa de anomalie Angle arată că 55,42% dintre subiecţi aparţin Clasei I Angle şi doar 12,57% Clasei II1 Angle unde se semnalează de altfel prin overjet-ul mai mare de 6 mm anomaliile scheletale.

CONCLUZII

Forme clinice variate de anomalii dento – maxilare caracteristice fiecărei etape de vârstă se datorează asocierii diferitelor obiceiuri vicioase şi intensităţii sau duratei acestor tulburări funcţionale.

Datele prelucrate pe parcursul studiului nostru confirmă datele din literatura, interrelaţia obiceiuri vicioase cu anomaliile dento – maxilare fiind susţinută de preva-

lenţa crescută a obiceiurilor vicioase şi a anomaliilor dento – maxilare de cauză disfuncţională.(4, 5)

Prevalenţa crescută a anomaliilor dento – maxilare (52,57%) precum şi interrelaţia evidentă cu dezechilibrele funcţionale ale aparatului dento – maxilar (62,82% din subiecţii examinaţi susţin implicaţia factorilor funcţionali în etiologia anomaliilor dento – maxilare.

Suprimarea obiceiurilor vicioase prin metode de conştientizare, miogimnastică şi reducere funcţională reprezintă aspecte de intervenţie ale tratamentului funcţional asupra formelor incipiente sau deja constituite de anomalii dento – maxilare.(6)

Dispensarizarea activă a colectivelor de copii preşcolari şi şcolari este forma ideală de combatere şi interceptare a disfuncţiilor şi obiceiurilor vicioase şi, prin urmare, verificarea reală în masă a conceptului de anomalie dento – maxilară.

SUCCINIC ACID PRODUCTION USING MOBILE BED OF IMMOBILIZED *ACTINOBACILLUS SUCCINOGENES* IN ALGINATE (Abstract) : This work investigates the production of succinic acid by immobilized *A. succinogenes* cells, using a bioreactor with stirred/mobile bed of biocatalysts. **Material and method** : The experiments have been carried out for different sizes of biocatalysts particle, under substrate and product inhibitory effects. **Results** : The results indicated that the inhibitory effects could be diminished by cells immobilization, the substrate consumption rate increasing with the increase of biocatalyst particle size. Moreover, the biocatalysts can be used for many fermentation cycles. **Key words :** *ACTINOBACILLUS SUCCINOGENES*, FERMENTATION, SUBSTRATE INHIBITION, SUCCINIC ACID

Acidul succinic, numit şi acid butandioic, este un acid dicarboxilic cu numeroase aplicaţii in industria chimică (reactivi, polimeri biodegradabili, solvenţi verzi, cerneluri), în agricultură (pesticide, factori de creştere, stimulatori), în industria farmaceutică şi alimentară (aminoacizi, antibiotice, surfactanţi, vitamine şi aditivi) (1,2,3,4).

In prezent, la nivel industrial, acidul succinic se obţine utilizând drept materie primă butanul din gazul petrolier lichefiat, prin intermediul anhidridei maleice. Costul obţinerii prin sinteză a acestui acid variază între 5,9 - 9 $/kg, în funcţie de puritate, aportul materiei prime la acesta fiind de 1,03 $/kg acid succinic. În afara dificultăţii etapelor de separare şi purificare a acestui acid, utilizarea tehnologiilor de sinteză chimică creează probleme serioase privind protecţia mediului ambiant (4). Din acest motiv, a crescut interesul pentru obţinerea acidului succinic pe cale fermentativă, cu costuri reduse, conform conceptului de „biotehnologie albă". Acesta a fost introdus cu ocazia Conferinţei Internaţionale "European Bioperspectives - En Route to a Knowledge-Based Bio-Economy" (Cologne, Germania, 31 mai – 1 iunie 2007), şi susţine prioritatea folosirii de materiale regenerabile pentru producţia de diverşi compuşi chimici prin procese biotehnologice ieftine ce protejează mediul înconjurător (5). Prin prisma acestor precepte, au fost studiate numeroase microorganisme cu potenţial producător de acid succinic raportate în literatură : bacterii (*Veillonella parvula, Selenomonas ruminatum*, *Succiniclasticus ruminis*, *Corynebacterium glutamicum, Enterococcus fecalis*, *Actinobacillus succinogenes*, *Actinobacillus succiniproducens*, *Mannheimia succiniproducens*, *Escherichia coli*), drojdii (*Saccharomyces cerevisiae*) şi fungi (*Aspergillus niger*, *Aspergillus fumigatus*, *Byssochlamys nivea*, *Lentinus degener*, *Paecilo-*

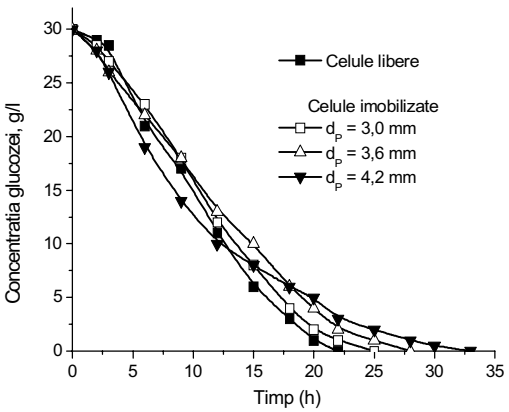

Fig. 1. Consumul glucozei pentru *A. succinogenes* liberă şi imobilizată, ciclul I de fermentaţie

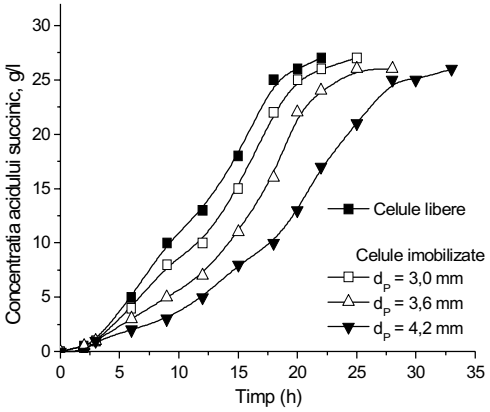

Fig. 2. Variaţia concentraţiei acidului succinic pentru *A. succinogenes* liberă şi imobilizată, ciclul I de fermentaţie

myces varioti, *Penicillium viniferum*) (6).

Majoritatea sistemelor de fermentaţie pentru obţinerea acidului succinic au utilizat celule libere de *Actinobacillus succinogenes*, procesul putând fi afectat de fenomene de inhibiţie de substrat şi produs (7,8).

Utilizarea microorganismelor sau a enzimelor imobilizate oferă o serie de avantaje, precum rezistenţă crescută la forţele de forfecare, rezistenţă chimică şi termică ridicată, diminuarea sau evitarea proceselor de inhibiţie, recuperarea uşoară a biocatalizatorilor din mediul de fermentaţie şi creşterea numărului de cicluri repetate de fermentaţie utilizând aceiaşi biocatalizatori (9).

În acest context, prin experimentele din această lucrare s-a realizat o analiză comparativă a obţinerii acidului succinic cu ajutorul celulelor libere şi celulelor imobilizate în alginat, în strat mobil. De asemenea, pentru sistemul cu celule bacteriene imobilizate şi în condiţii de inhibiţie de substrat şi de produs, au fost investigate transferul de masă al substratului în exteriorul şi în interiorul granulei de biocatalizator, evidenţiindu-se implicarea difuziei interne în desfăşurarea acestui proces.

MATERIAL ŞI METODĂ

Experimentele s-au realizat în bioreactoare anaerobe cu capacitatea de 100 mL (80 mL volum util) simultan, fiecare conţinând 54 mL mediu cu următoarea compoziţie (pe litru): glucoza 30 g; extract de drojdie 5 g; $NaH_2PO_4 \cdot H_2O$ 1,16 g; Na_2HPO_4 0,31 g; NaCl 1,0 g; $MgCl_2 \cdot 6H_2O$ 0,2 g; $CaCl_2 \cdot 2H_2O$ 0,2 g; vitamină B_{12} 1 μg; biotină 20 μg; acid folic 20 μg; tiamină 50 μg; riboflavină 50 μg; niacină 50 μg; pantotenat 50 μg; p-aminobenzoat 50 μg; acid lipoic 50 μg; vitamină B_6 100 μg; $MgCO_3$ 10 g; antispumant siliconic 1 ml. Bioreactoarele au fost plasate pe un agitator rotativ la 100 rpm şi incubate la 37°C pe întreaga durată a fermentaţiei. În timpul procesului de fermentaţie, în mediu a fost barbotat CO_2 cu un debit de 0,1 L/l mediu pe minut.

În aceste experimente a fost folosită bacteria *A. succinogenes* ATCC 55617 imobilizată în alginat. Microorganismul a fost furnizat de American Type Culture Collection şi păstrat în frigider la -70°C.

Imobilizarea s-a realizat prin incluziunea celulelor bacteriene într-o matrice de alginat. Prepararea biocatalizatorilor s-a realizat în condiţii aseptice, separat pentru fiecare bioreactor. În acest sens, s-au adăugat 6 ml de inocul peste 20 ml soluţie 5% alginat de sodiu. Granulele de biocatalizator au fost obţinute prin picurarea acestei suspensii sub presiune constantă, prin capilare, sub

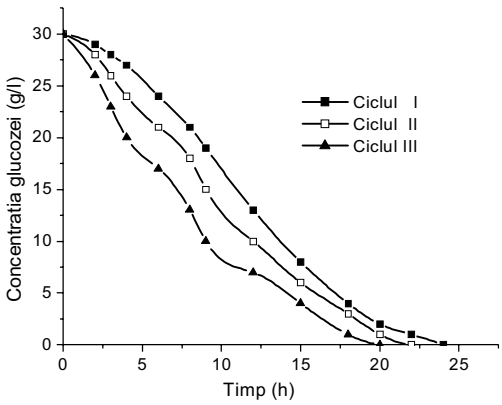

Fig. 3. Variaţia concentraţiei substratului în timpul fermentaţiei cu *A. succinogenes* celule imobilizate

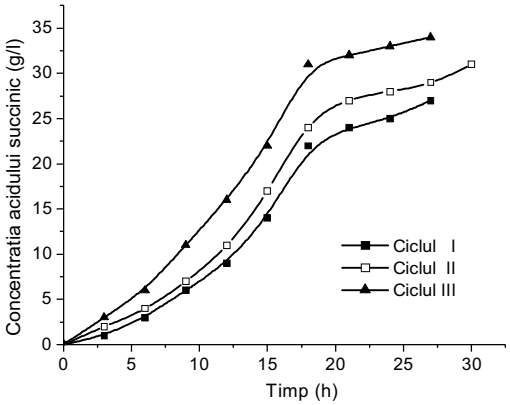

Fig. 4. Variaţia concentraţiei produsului în timpul fermentaţiei cu *A. succinogenes* celule imobilizate

agitare, într-o soluţie 0,2% clorură de calciu. Au fost utilizate 3 capilare de dimensiuni diferite, astfel încât au fost obţinute granule de *A. succinogenes* imobilizate cu 3 diametre: 3; 3,6 şi 4,2 mm. În toate cazurile fracţia volumică a celulelor în mediul de fermentaţie a fost de 0,28.

Fermentaţia s-a considerat încheiată atunci când substratul a fost consumat în întregime sau când concentraţia acestuia nu s-a modificat timp de 12 ore. Concentraţia substratului a fost măsurată la fiecare 2 sau 3 ore pe parcursul fermentaţiei cu ajutorul analizorului de glucoză de tip Analox GL 6.

Conţinutul de acid succinic din lichidul de fermentaţie a fost dozat folosindu-se tehnica HPLC (echipament Star Varian Chromatography Workstation), utilizând ca fază mobilă o soluţie de acid trifluoracetic 0,1%. Coloana de tip Shimadzu CTO-6A a funcţionat la temperatura de 60°C.

REZULTATE ŞI DISCUŢII

Datorită difuziei interne a substratului in interiorul particulelor de biocatalizator, concentraţia substratului este diminuată în apropierea centrului activ, ceea ce duce la reducerea vitezei proceselor biochimice (creşterea biomasei şi formarea produsului) comparativ cu sistemele ce folosesc bacterii libere. Apariţia difuziei interne, în cazul imobilizării celulelor, ar putea atenua efectele inhibitorii.

Astfel, din figura 1 se poate observa că durata fermentaţiei succinice pentru bacteria *A. succinogenes* liberă este de aproximativ 22 de ore, perioada lag fiind de 3 ore. Durata procesului de fermentaţie a crescut prin utilizarea celulelor imobilizate devenind de 25 de ore pentru granulele cu diametrul de 3 mm, 28 de ore pentru cele de 3,6 mm şi 33 de ore pentru granulele cu diametrul de 4,2 mm. Această variaţie este consecinţa difuziei interne a glucozei în granula de biocatalizator, proces care reduce concentraţia substratului în interiorul particulelor şi, implicit, viteza de consum a glucozei.

Aparent, perioada lag nu este atât de evidentă în cazul bacteriei *A. succinogenes* imobilizate, posibil datorită difuziei glucozei dinspre faza lichidă spre biocatalizatori. Însă, pentru primele 12 ore, cea mai ridicată viteză de utilizare a substratului este atins pentru granulele de biocatalizator cu diametrul de 4,6 mm. Acest rezultat evidenţiază efectul pozitiv al difuziei interne în fermentaţia succinică în condiţiile inhibiţiei de substrat. După 12-15 ore, atunci când concentraţia glucozei este mai mică decât cea care ar induce efectul de inhibiţie, difuzia internă devine un factor limitativ pentru procesul de fermentaţie, iar viteza de consum a

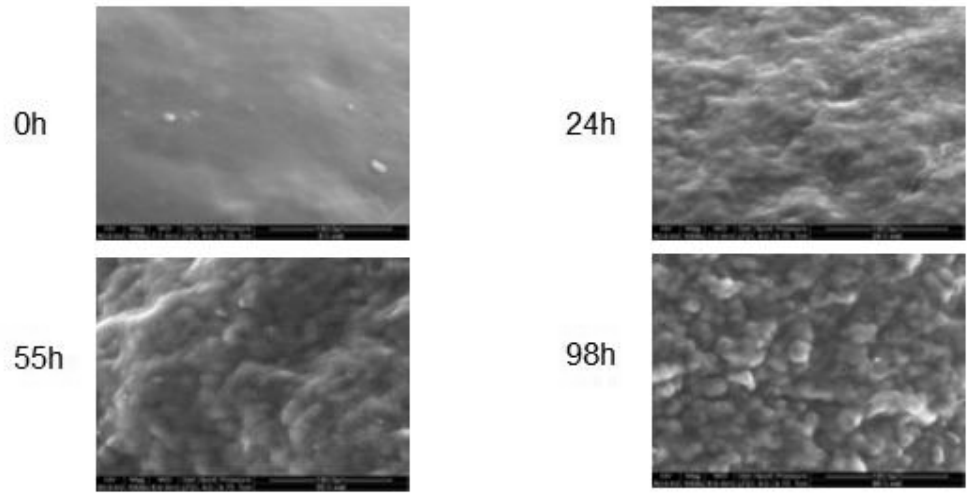

Fig. 5. Imagini SEM ale granulei de biocatalizator

substratului se reduce, fenomen mai evident la dimensiuni mai ridicate ale granulelor.

În acelaşi timp, s-a constatat că prin utilizarea bacteriilor imobilizate şi prin creşterea diametrului granulelor de biocatalizator se reduce viteza de producere a acidului succinic, datorită acumulării sale în interiorul granulelor şi apariţiei fenomenului de inhibiţie de produs (fig. 2).

Aceiaşi biocatalizatori au fost folosiţi pentru 3 cicluri succesive de fermentaţie succinică şi s-a constat că, pentru aceleaşi granule, viteza de consum a glucozei şi viteza producerii acidului succinic cresc de la un ciclu la altul, fenomen ce se datorează dezvoltării bacteriilor în interiorul granulelor (fig. 3, 4).

Dezvoltarea bacteriilor în interiorul biocatalizatorilor a cauzat distrugerea granulelor la finalul celui de-al treilea ciclu, fapt evidenţiat prin măsurarea turbidităţii mediului. De asemenea, dezvoltarea biomasei în interiorul granulelor de biocatalizatori este dovedită şi de imaginile SEM obţinute în diferite momente pe parcursul celor trei cicluri de fermentaţie succinică (fig. 5).

CONCLUZII

Experimentele prezentate au abordat fermentaţia succinică într-un bioreactor cu strat mobil de *A. succinogenes* imobilizate în alginat, în condiţiile inhibiţiei de substrat şi produs. Studiile s-au concentrat pe efectul imobilizării celulelor bacteriene asupra vitezelor de consum a glucozei şi producere a acidului succinic, precum şi pe posibilitatea realizării mai multor cicluri de fermentaţie succesive.

Rezultatele obţinute au indicat faptul că efectul inhibitoriu al substratului poate fi diminuat prin imobilizarea bacteriilor, gradul de consum al glucozei crescând odată cu creşterea dimensiunii particulelor de biocatalizator.

Studiile viitoare vor urmări transpunerea proceselor realizate din sistemul cu strat mobil de biocatalizator într-un sistem ce foloseşte stratul fix tip „basket”.

Facultatea de Medicină dentară
3. Disciplina de Farmacologie

FLAVONOIDS - BIOACTIVE COMPOUNDS IN FRUITS JUICE (Abstract): Since 1989, grapefruit juice is reported to modify, with clinical implications, the pharmacokinetic of a series of drugs such as calcium channel blockers that are dihydropyridine derivates and/or some HMGCoA reductase inhibitors. All these drugs are metabolized to a large extent by the most abundant human isoform of cytocrome P450, CYP3A4. Grapefruit inhibits the cytocrome P450 3A4 enzyme system responsible for the oxidative metabolism of many orally administered drugs. The most important compounds of GFJ considered to be involved in the pharmacokinetic interaction are flavonoids (naringin, naringenin, narirutin, quercetin, kaempferol, hesperidin, neohesperidin, didymin, and poncirin), furanocoumarins (6',7'-dihydroxy-bergamottin, bergamottin, bergamottin-6',7'-epoxide, bergapten, epoxy-bergamottin) and sesquiterpens (nootkatone). **Material and method**: The experimental researches had as object the comparative study of total content of flavonoidic compounds, like naringin in different fruit juices: citric fruit (white, pink and red grapefruit), apples, pears - industrial or laboratory prepared juices (by squeezing). They praised a different content in flavonoidic compounds for citric and for the rest of analyzed fruits. **Results**: For grapefruit juices the concentrations in flavonoidic compounds are higher in total fruit juice: 143.86 mg/100 mL in red, 131.47 mg/100 mL in pink and 84.21 mg/100 mL in white grapefruit juice. In juice prepared from fruit pulp, the concentrations were 81.92 mg/100 mL, 108.23 mg/100 mL and 65.76 mg/100 mL, respectively. The content in naringin, the most important flavanone in citrus fruit, varied between 1.98 and 51.2 mg/100 mL juice. **Key words**: GRAPEFRUIT, FLAVONOID, NARINGIN, PHARMACOKINETIC INTERACTION

Produsele alimentare de origine vegetală conţin, pe lângă componentele cu rol biologic cunoscut, indispensabile în alimentaţia omului (macro- şi micronutrienţi), şi alte substanţe (pigmenţi naturali, acizi organici, enzime, uleiuri volatile) în concentraţii foarte mici care pot îndeplini, în aliment sau în organism, roluri specifice. Aceste substanţe sunt denumite cu un termen generic "substanţe bioactive"; trebuie precizat că o parte dintre acestea prezintă interes nutriţional şi se numesc "fiziologic active", iar altă parte prezintă, mai ales interes terapeutic (in domeniul fitoterapiei) - substanţe "farmacologic active"(1).

Sucul de grapefruit (SGF) este consumat frecvent pentru gustul său plăcut, pentru valoarea nutritivă, dar şi pentru aportul de substanţe bioactive (flavone, furanocumarine, vitamine). Tradiţional, sucul de grapefruit este consumat pentru acţiuni multiple: antioxidant, antinitrozaminic, antiseptic, cardiotonic, detoxifiant, hipocolesterolemiant, sedativ, stomahic (2,3). Studii experimentale

(4,5) au sugerat că sucul de grapefruit reduce formarea plăcilor aterosclerotice şi inhibă proliferarea unor celule canceroase (cancer mamar, pulmonar, de colon). Recent au fost publicate numeroase date care confirmă acţiunea hipocolesterolemiantă a componentelor bioactive din sucul de grapefruit (6,7).

Existenţa interacţiunii între sucul de grapefruit şi unele medicamente blocante ale canalelor de calciu (felodipina şi nifedipina) a fost evidenţiată din întâmplare în anul 1991, în urma unui studiu al interacţiunii etanol-medicament în care sucul de grapefruit a fost utilizat ca vehicul pentru alcoolul folosit în studiu (8). De atunci au fost publicate rezultatele a numeroase studii privind interacţiunea sucului de grapefruit cu diferite medicamente şi importanţa clinică a acestora, mecanismul interacţiunii, componentele bioactive din produsul alimentar responsabile de producerea interacţiunii (2).

Medicamentele care interacţionează cu sucul de grapefruit sunt supuse în organism unui metabolism oxidativ, sub acţiunea citocromului P450, în peretele intestinal sau în ficat. Sucul de grapefruit conţine flavonoide care afectează sistemul citocrom P450 (CYP), în special izoenzimele CYP1A2 şi CYP3A4, prin ataşare la izoenzimă, ca substrat, şi astfel este afectată prima etapă a metabolismului prin inactivare directă sau prin inhibarea enzimei. Efectul major asupra enzimelor CYP constă într-o inhibare selectivă a CYP3A4 din intestinul subţire (9). Intensitatea interacţiunii dintre sucul de grapefruit şi medicamente din clase terapeutice diferite, cu structuri chimice variate, este influenţată de modul de preparare al sucului (pulpa, pulpă şi albena, fruct integral) şi de varietatea de fruct (3,10,11) utilizată (grapefruit alb, roz sau roşu).

În prezent este confirmat faptul că şi alte componente bioactive din produse de origine vegetală (legume, fructe, plante medicinale), pot interacţiona cu unele medicamente. Astfel, Banfield et al. (12) a evidenţiat modificarea marcantă a parametrilor farmacocinetici (aria de sub curbă, concentraţia maximă, timp de înjumătăţire) la administrarea simultană la subiecţi umani de fexofenadină şi suc de mere. Concluzia care de desprinde din aceste rezultate este aceea că se impune o nouă abordare privind interacţiunile dintre medicamente şi sucurile din produse vegetale.

Cercetările experimentale prezente au ca obiectiv studiul comparativ al conţinutului total în flavonoide, respectiv în naringină pentru diferite sucuri de fructe : citrice (grapefruit alb, roz şi roşu, portocale, mandarine), mere, pere - preparate industrial sau în laborator.

MATERIAL ŞI METODĂ

Probe de analizat

Probele supuse analizei (tab. I) au fost sucuri de grapefruit (alb, roz şi roşu), de portocale, de mandarine, de pere şi de mere - preparate industrial (din comerţ) sau în laborator, utilizând storcătorul de fructe. Sucurile de citrice preparate în momentul utilizării (în laborator) s-au realizat în trei variante : suc din pulpa fructului (I), din pulpa fructului şi albena (II) şi din fructul integral (III). Sucurile preparate industrial au fost achiziţionate din reţeaua comercială a oraşului Iaşi.

Studiul cromatografic

Identificarea flavonoidelor din sucurile de fructe s-a realizat prin cromatografie pe strat subţire pe suport de silicagel, în sistem ascendent (metoda standardului extern). Ca substanţe de referinţă s-au utilizat rutozida şi naringina.

Determinarea cantitativă a flavonoidelor

Determinarea conţinutul total în flavonoide exprimat în naringină s-a realizat prin tehnica prezentată în Farmacopeea Română, ediţia a X-a, monografia *Cynarae folium* (13). Calculul conţinutului în flavonoide al

probelor de suc, exprimat în mg naringină/ 100 mL s-a realizat cu ajutorul curbei de calibrare trasate în prealabil, pentru domeniul de concentraţii 0-50 μg. Separarea flavonoidelor din probele de sucuri de fructe în vederea determinării spectrofotometrice s-a realizat prin tratare cu metanol anhidru (1 : 1, v/v) şi centrifugare timp de 15 minute la 3000 RTM. Cotă parte din lichidul supernatant a fost prelucrat în modul indicat la trasarea curbei de etalonare.

Determinarea conţinutului în naringină

Pentru probele de suc de fructe luate în studiu s-a determinat conţinutul în naringină prin metoda aplicată la determinarea flavonoidelor totale după separarea acesteia prin cromatografie preparativă pe strat subţire (standard extern), pe suport de poliamidă, cu dublă developare în sistemul de solvenţi metanol – nitrometan (2 : 5). Revelarea cromatoplăcilor s-a realizat cu soluţie de triclorură de aluminiu 1% în alcool etilic şi expunere la lumină Wood. Banda corespunzătoare naringinei a fost raclată de pe placa cromatografică, adusă într-o eprubetă uscată şi extrasă cu 1,5 – 2 ml amestec metanol - etilenglicol - apă - hidroxid de sodiu 4N (25 : 22,4 : 2,6 : 1). Calculul conţinutului în naringină al probelor de sucuri

analizate s-a realizat cu ajutorul curbei de calibrare trasate în prealabil, pentru intervalul de concentraţii 0 – 50 μg.

REZULTATE ŞI DISCUŢII

Tabloul cromatografic pentru identificarea prezenţei flavonoidelor în probele de sucuri de fructe este prezentat în fig. 1.

Spoturile corespunzătoare naringinei sunt suficient de delimitate şi au permis o bună separare a benzilor corespunzătoare acestei componente.

Curba de calibrare pentru determinarea flavonoidelor totale exprimate în naringină este prezentată în fig. 2.

Coeficientul de corelaţie R^2 obţinut are o valoare de 0,99899 care permite calculul conţinutului în naringină, respectiv în flavonoide totale al probelor analizate.

Conţinutul în flavonoide şi în naringină pentru probele de suc de grapefruit preparate în laborator este prezentat în fig. 3.

Se constată valori mai crescute ale flavonoidelor totale pentru sucul de grapefruit roşu preparat din fructul integral – 143,86 mg/100 mL; în sucurile preparate din pulpa fructului, concentraţiile variază de la 65,76 mg/100 ml pentru SGF alb la 108,23 mg/100 mL pentru SGF roz. Aceste valori sunt în concordanţă cu cele raportate de alţi autori (3,14,15) care au determinat în 9 sorturi diferite de suc concentraţii de flavonoide cuprinse între 19,44 şi 84,28 mg/100 mL.

Pentru sucurile de grapefruit preparate industrial (fig. 4) concentraţiile în flavonoide totale sunt cuprinse între 96,21 şi 102,54 mg/100 mL. Aceste valori sunt apropiate de cele determinate de alţi autori în sucuri preparate din fructul integral (14). Nectarul de grapefruit preparat industrial (proba 13) conţine 83,12 mg flavonoide la 100 mL produs.

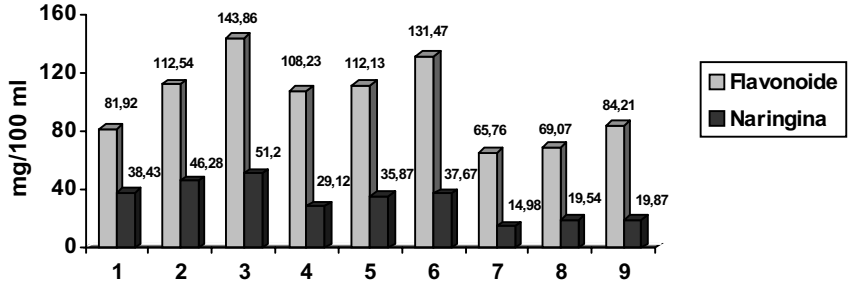

Fig. 3. Concentraţiile flavonoidelor totale şi ale naringinei în probele de suc de grapefruit preparate în laborator (probele 1-9)

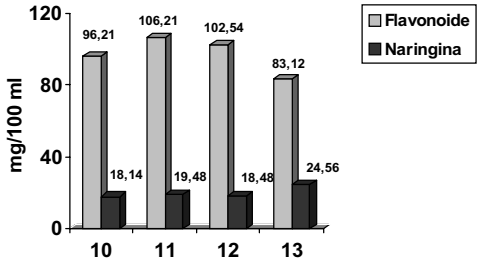

Fig. 4. Concentraţiile flavonoidelor totale şi ale naringinei în probele de suc de grapefruit preparate industrial (probele 10-13)

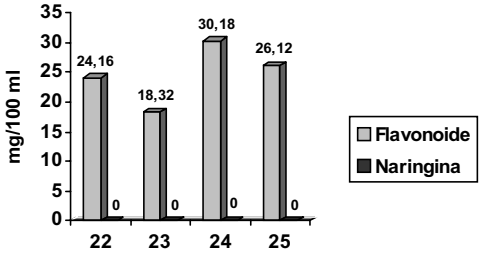

Fig. 6. Concentraţiile flavonoidelor totale în probele de suc de mere şi de pere (probele 22-25)

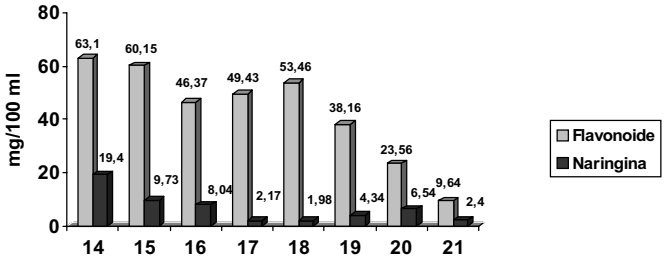

Fig. 5. Concentraţiile flavonoidelor totale şi ale naringinei în probele de suc de portocale şi de mandarine (probele 14-21)

În fig. 5 sunt prezentate concentraţiile flavonoidelor în sucurile de portocale şi de mandarine preparate în laborator sau procurate din comerţ. Pentru sucurile de portocale (probele 14-17) valorile concentraţiilor flavonoidelor variază între 46,37 mg/100 mL (suc de portocale preparat din pulpa fructului) şi 63,18 mg/100 mL (suc preparat din fructul integral). Pentru sucurile de mandarine (probele 18-22) valorile sunt ceva mai mici şi variază de la 9,64 mg/100 mL la sucul preparat industrial la 53,46 mg/100 mL la sucul preparat în laborator din fructul integral.

Pentru sucurile de pere şi de mere (fig. 6) s-au determinat concentraţii ale flavonoidelor totale cuprinse între 18,32 mg/100 mL şi 30,18 mg/100 mL produs.

Concentraţiile în naringină determinate în paralel cu conţinutul total în flavonoide (fig. 3-6) variază între 14,98 mg/100 mL pentru SGF alb preparat din pulpa fructului şi 51,20 mg/100 mL pentru SGF preparat din grapefruitul roşu, fructul integral. Sucurile de grapefruit preparate industrial (din fruct integral) conţin între 24,56 mg şi 29,48 mg naringină pentru 100 mL produs. Valorile conţinutului în naringină pentru probele de suc obţinute din portocale şi mandarine variază de la 1,98 mg/100 mL pentru sucul de mandarine preparat numai din pulpa fructului la 21,17 mg/100 mL pentru nectarul de portocale cu pulpă. În probele de sucuri de mere şi de pere nu a fost determinată naringina. Cromatografia pe strat subţire indică absenţa acestui compus din compoziţia sucurilor menţionate, rezultat în concordanţă cu datele din literatura de specialitate (16).

CONCLUZII

Determinarea conţinutului în flavonoide totale în sucuri de fructe (citrice, mere, pere) preparate industrial sau în laborator a evidenţiat valori diferite atât în funcţie de natura fructului, cât şi în funcţie de modul

de preparare al sucului. Sucul preparat din fructul integral este mai bogat în flavonoide, respectiv în naringină, comparativ cu sucul preparat din pulpa fructului.

Sucurile preparate industrial, din fruct integral, prezintă valori ale conţinutului în flavonoide apropiate de cele preparate în laborator. Diferenţele constatate între concentraţiile în componentele bioactive ale sucurilor de fructe explică intensitatea diferită a interacţiunilor farmacocinetice care se manifestă la administrarea simultană cu medicamente din clase terapeutice diferite.

2. Disciplina de Medicina Muncii

SOME ASPECTS REGARDING OCCUPATIONAL HEALTH IN SMALL AND MIDDLE ENTERPRISES (Abstract): The objective of the study was to assess occupational health services in small and medium enterprises (SME's) in Bacău, between 2007 and 2008, in order to increase the quality of services' management. **Material and method**: Five hundred seventy nine SME's with 21,815 employees have been studied, with a number of employees varying from ten to 250 per enterprise. About 4478 employees, out of which 587 with different occupational exposures, have no occupational health services provided on a contract basis. **Results**: The high number of occupational diseases and work related accidents in SME's show a low level of concern for occupational health and safety matters, compared to big enterprises. The employees' opinions showed that the role of occupational health is not known, there is no concern for the medical adaptation of new employees or old employees rehired after a long break, the employees do not consult occupational health services on their own accord. The occupational services do not fully satisfy the need. The study offers useful data to physicians and SME's management in order to improve the occupational health management. **Key words**: OCCUPATIONAL HEALTH SERVICES, SMALL AND MIDDLE ENTERPRISES, INTERVENTION RESEARCH

Din 1989 toate statele Uniunii Europene au avut ca obligaţie, pe măsura aderării, transpunerea în legislaţia naţională a Directivei Consiliului 89/391/CEE din 12 iunie 1989 privind punerea în aplicare de măsuri pentru promovarea îmbunătăţirii securităţii şi sănătăţii lucrătorilor la locul de muncă (1,2). Angajatorul are doar obligaţia de a asigura protecţia stării de sănătate a angajaţilor în condiţiile existente la locul de muncă.

Activităţile de medicina muncii sunt organizate în raport de consideraţiile economice şi pot fi practicate de asistenţi medicali specializaţi, medici de medicină generală sau specialişti de medicina muncii (3,4,5).

MATERIAL ŞI METODE

În studiu s-au inclus informaţiile privind numărul întreprinderilor şi al angajaţilor acestora, tipurile şi nivelurile riscurilor pentru sănătate, situaţia bolilor profesionale şi accidentelor de muncă, şi opiniile angajaţilor privind riscurile şi natura îngrijirilor pentru sănătate. De asemenea, Direcţia Generală a Finanţelor Publice, Bacău a furnizat datele privind asigurarea cu servicii de medicina muncii pe bază de contract.

Evidenţele Direcţiei de Sănătate Publică

Bacău şi ale Compartimentului Accidente de Muncă şi Boli Profesionale din cadrul Inspectoratului Teritorial de Muncă Bacău, au permis realizarea unor aprecieri privind situaţia existentă în IMM-uri, în raport de particularităţile grupurilor de angajaţi (6).

REZULTATE ŞI DISCUŢII

Particularităţi ale structurilor incluse în studiu. În anii 2007 şi 2008, au fost în activitate 579 IMM cu 21815 angajaţi, dintre care 451 întreprinderi mici cu 9079 angajaţi, şi 128 întreprinderi mijlocii cu 12736 angajaţi, cu variate profiluri de activitate şi de asistenţă pentru sănătate (tab. I).

Serviciile de medicina muncii. Din total angajaţi în IMM-uri, 20,5% nu beneficiază de asistenţa medicului de medicina muncii,

situaţie întâlnită îndeosebi în sectoarele de comerţ, construcţii şi servicii (fig. 1).

Asigurarea cu servicii de medicina muncii rămâne, în continuare, pentru angajatorul român, doar o obligaţie legală (Legea nr. 319 din 14 iulie 2006, a securităţii şi sănătăţii în muncă) (7).

Dacă toţi cei 12 medici care îşi desfăşurau activitatea în teritoriul la care ne referim, ar fi încheiat contracte cu IMM-urile cu peste 10 angajaţi, fiecăruia i-ar fi revenit 1855 de angajaţi.

Riscurile ocupaţionale pentru sănătate au făcut obiectul unui alt studiu, din care rezultă că prezenţa factorilor de risc a fost constatată la 22% din angajaţii întreprinderilor mici şi la 31% din angajaţii celor mijlocii. Pe primele 3 locuri s-au situat suprasolicitarea vizuală, musculo-osteo-articulară şi expunerea la pulberi textile.

Măsurătorile de noxe au arătat că LMA sunt depăşite în proporţie de 35%, îndeosebi pentru pulberile cu SiO_2 şi de lemn, precum şi pentru zgomot şi solvenţii organici. Deşi s-a constatat că 10,1% din angajaţii expuşi la noxe nu sunt supravegheaţi medical, în relaţie cu riscurile ocupaţionale, s-a evidenţiat implicarea angajatorilor în supravegherea lucrătorilor expuşi la noxe (tab. II).

Percepţia negativă asupra condiţiilor de muncă a fost exprimată în medie de 14,35% dintre angajaţi, cu proporţii diferite, în funcţie de profilul muncii (1,75-85%).

Evaluări pentru perioada 2005-2007. În cei 3 ani luaţi în studiu, au fost declarate 23 cazuri de boli profesionale, reprezentând 79,31% din totalul de 29 declarate în toate întreprinderile din municipiu. În proporţie de 90% acestea provin din industria metalurgică, secţia de turnătorie (silicoză, hipoacuzie / surditate şi iritaţii ale căilor aeriene superioare). Au fost înregistrate şi cazuri de astm bronşic (confecţii, panifi-

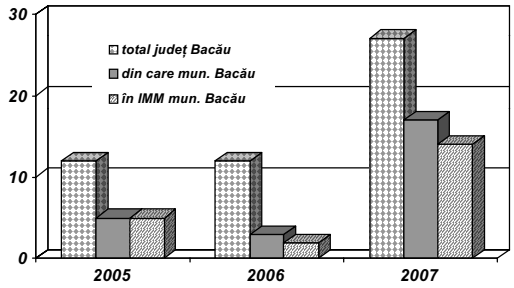

Fig. 2. Repartiţia numărului de cazuri de boli profesionale declarate în perioada 2005-2007

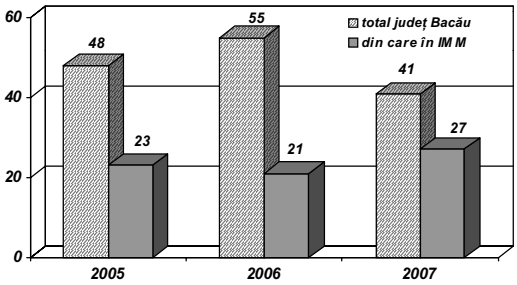

Fig. 3. Numărul accidentelor de muncă declarate în perioada 2005-2007

caţie), boli musculo-osteo-articulare (silvicultură, industria chimică), şi iritaţii ale căilor aeriene superioare (construcţii, prelucrare petrol) (fig. 2).

În aceeaşi perioadă (2005-2007), în IMM au fost înregistrate 71 accidente de muncă, reprezentând 49,3% din totalul de 144 pentru toate întreprinderile din municipiu (fig. 3).

S-a remarcat faptul că, în întreprinderile mijlocii, numărul accidentelor este de 3 ori mai mare decât în cele mici, ele reprezentând 2/3 din totalul accidentelor din municipiu. Situaţia se explică prin numărul mare de întreprinderi de construcţii, în care riscul de accidentare este crescut.

Numărul mai mare al cazurilor de boli profesionale şi accidente de muncă în IMM faţă de cel din întreprinderile mari reflectă nivelul scăzut al organizării şi preocupărilor de promovare a sănătăţii şi securităţii în muncă.

Oferta de servicii de medicina muncii. În municipiul Bacău, în anii 2007 şi 2008, asistenţa de medicina muncii era asigurată de trei tipuri de unităţi: 4 cabinete medicale individuale, 4 clinici particulare, şi cabinetul de medicina muncii din ambulatoriul spitalului judeţean. În aceste unităţi, erau încadraţi 12 medici de medicina muncii care asigurau servicii pentru salariaţii întregului judeţ. La aceştia se adăugau 20 medici de alte specialităţi care şi-au câştigat dreptul de a practica medicina de întreprindere prin cursuri speciale. Se apreciază că oferta de servicii de medicina muncii pentru angajaţii din IMM, cât şi pentru celelalte întreprinderi, nu corespunde cerinţelor. Legislaţia din România nu prevede un număr maxim de salariaţi, care poate fi asistat de medicul de medicina muncii. Studiul nostru oferă medicilor, angajatorilor şi legiuitorilor, o bază de date în scopul creşterii, în viitor, a volumului şi calităţii managementului sănătăţii ocupaţionale în IMM.

CONCLUZII

Studiile privind nevoile şi oferta de servicii de medicina muncii pentru angajaţii din IMM sunt încă în număr redus. Datele pe această temă din ţările Uniunii Europene pot fi utile, impunându-se şi studiul particularităţilor din România. Oferta şi calitatea serviciilor de medicina muncii se cere a fi reconsiderată şi adaptată nevoilor care apar, în concordanţă cu transformările socio-economice ale IMM, care prezintă mare mobilitate şi instabilitate. Prin destrămarea marilor întreprinderi şi absorbţia forţei de muncă de IMM-uri, municipiul Bacău poate fi luat ca exemplu din acest punct de vedere. În aceste condiţii, o cerinţă de prim ordin pentru Direcţia de Sănătate Publică este de a asigura oferta de servicii de medicina muncii tuturor angajaţilor din IMM, pe bază de contract. Tabloul polimorf al activităţilor din IMM, al riscurilor pentru sănătate şi producerea unor boli, impune organizarea de structuri diversificate de medicina mun-

cii, care să satisfacă nevoile de sănătate ocupaţională ale angajaţilor.

Cazurile de boli ocupaţionale şi accidentele de muncă, semnificativ mai numeroase în IMM decât în întreprinderile mari, ca şi existenţa unor riscuri reale pentru sănătate, sunt consecinţa minimalizării preocupării angajatorilor pentru sănătatea şi securitatea în muncă. În acelaşi timp, angajaţii nu sunt educaţi pentru a înţelege importanţa măsurilor prevenţionale şi de asistenţă prin medicina muncii, la care apelează doar în caz de îmbolnăvire, iar cei cu boli cronice solicită rar ajutorul medicului de medicina muncii, putând evidenţia relaţia dintre unele aspecte ale muncii şi anumite stări patologice.

În prezent, se impun măsuri care să amelioreze interrelaţiile medicilor de medicina muncii şi de alte specialităţi, în rezolvarea problemelor complexe pe care le ridică promovarea sănătăţii ocupaţionale.

MANAGEMENT AND PREVENTION OF ORAL MANIFESTATIONS FOR BLOOD DYSCRASIA AND VIRAL PATHOLOGY (Abstract): The study outlines the dentist's attitude in dealing with two of the many serious diseases throughout the body, HIV infection and acute leukemia. Many systemic diseases have oral manifestations which may appear at the beginning of any developed pathology, thus early detection can occasionally occur at the dental clinic. Gingival lesions are the most common oral phenomenon known for leukemia and HIV infection. In this case an early detection of pathology at the dental clinic was based on an uncommon and single presenting sign of massive spontaneous gingival bleeding. The objectives are demonstrate this unusual sign of blood dyscrasia and HIV infection in oral cavity and establishing management and prevention of oral manifestations for blood dyscrasia and pathology with viral etiology. **Material and method**: We investigated 225 cases had pathology with viral etiology. The patients entered the study HIV / AIDS in Botoşani, Suceava, Neamţ during 2004-2008. All patients had a detailed medical history and examination as well as a thorough oral examination, which were all done without prior knowledge of the patient's HIV serostatus. **Results**: Oral disease is frequently associated with HIV. While nearly all oral disorders associated with HIV infection also occur in other conditions characterized by immunosuppression, no other condition is associated with as wide and significant a spectrum of oral disease as is HIV infection. Many HIV associated oral disorders occur early in HIV infection, not infrequently as the presenting sign or symptom. Thus, early detection of associated oral disease should, in many cases, result in earlier diagnosis of HIV infection. Likewise, awareness of the variety of oral disorders which can develop throughout the course of HIV infection, and coordination of health care services between physician and dentist, should improve overall health and comfort of the patient. This paper reviews the clinical, diagnostic and therapeutic aspects of HIV associated oral disorders. **Conclusions**: Diseases with a particular viral etiology infectiousness have a special resurgence. For the dentist, their recognition has a particularly importance for the quick and accurate determination of the diagnose and for the establishing, together with the infectious disease physician, of the appropriate treatment. Working with the department of epidemiology is useful to define the preventive measures among the community. **Key words**: ORAL MANIFESTATION, HIV INFECTION, BEHAVIORAL STRATEGIES, PREVENTION, ACUTE LEUKEMIA

POLYMERIC MATERIALS AS NANOFIBERS USED IN THE TREATMENT OF BURNS

POLYMERIC MATERIALS AS NANOFIBERS USED IN THE TREATMENT OF BURNS (Abstract): This paper deals with a short review on the state-of-the-art of the use of nanofibers as wound dressing materials. Nanofibers have potential for use in a wide range of applications due to their biodegradability, low cost and high efficiency. Given the complexity of burn therapy, there is an increasing need for investigating the therapeutic options of wound healing process. The use of nanofibrous materials for burn care is preferable due to their structural similarity whit that of native extracellular matrix. The preparation methods of nanofibers have been extensively studied and some techniques have been reported to produce materials for different applications. Special attention was focused on the preparation of micro- and nanofibrous materials with antibacterial and antifungal activity. **Keywords:** BURN THERAPY, WOUND HEALING, POLYMERS, NANOFIBERS, ELECTRO-SPINNING.

Wound healing is one of the most complex biological events, as a result of the interaction of different tissue structures with a large number of infiltrating cell types as leukocyte subsets (neutrophils, macrophages). The normal healing response begins when the tissue is injured and continues with tissue repair process which involves re-epithelialization, formation of granulation tissue and contraction of underlying wound connective tissues (1). During the healing process, collagen production is essential for epithelial migration and proliferation in the first days after injury (2). Given the complexity of burn therapy and the high incidence of burn injuries and burn-related deaths (approximately 322.000/year) (3), there is an important need for experimental studies on the therapeutic options of wound healing and tissue regeneration.

In the field of wound care, wound dressings have brought the attention of researchers, so far. The treatment of burns requires a material that will restore the epidermal function and will promote the

healing process (2). The ideal wound dressing must have properties that allow the absorption of exudates, inhibition of the growth of microorganisms (4) and also must have high porosity for respiration. Traditional dressings such as natural or synthetic bandages have been extensively used, but they have limited swelling capacity and moisture vapor permeability. In this context, the use of nanofibrous materials is preferable due to their structural similarity to that of native extracellular matrix (5).

On the other hand, nowadays polymeric materials play an important role in many applications, starting from daily needs to biomedical applications.

TECHNIQUES USED TO OBTAIN NANOFIBRES

Nanofibers have been extensively studied and some techniques for producing this type of materials for biomedical applications have been reported. Of these, electrospinning is the most studied technique as it seems to generate the most promising results for biomedical applications (fig. 1).

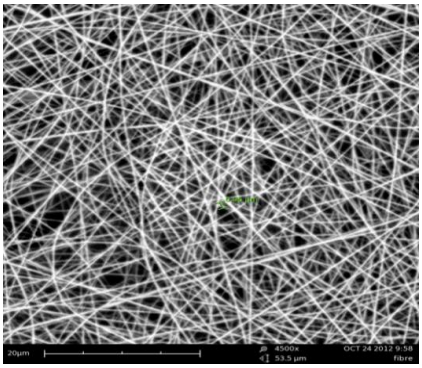

Fig. 1. SEM images of Chitosan nanofibers

The Force-spinning method has been successful used to obtain nanofibers of poly-ethylene oxide, poly-lactic acid, polypropylene, acrylonitrile-butadiene-styrene, polyvinyl pyrrolidone and polystyrene (6). This method uses centrifugal force and parameters such as rotational speed of spinneret, collection system and temperature to control the morphology of the obtained nanofibers.

Template synthesis uses a nanoporous membrane as a template to make nanofibers. The disadvantage of this method is that the process takes a relatively long time to transfer the solid polymer into the nanoporous foam (7).

Mechanical treatments such as cryocrushing (8), grinding (9) and high-pressure homogenizing (10) could be also applied for getting nanofibers.

Chemical treatments such as *acid hydrolysis* provide preparation methods of stable nanofibers. Acid hydrolysis of the biomass involves the use of mineral acids like sulphuric acid, hydrochloric acid and phosphoric acid and produces micro- and nanofibers with a high degree of crystallinity by removing the amorphous regions of the material (11).

Biological treatments, such as enzyme assisted hydrolysis, may decrease the processing cost by lowering the number of passes through the homogenizer and has main advantages from environmental point of view as compared with chemical methods (12).

Electrospinning method. Starting with 1930, electrospinning has been used as a particularly important technique applied to generate fibrous materials used in a variety of applications, such as: filters, skin masks, semipermeable membrane, clothing and medical materials such as dressings, vascular grafts, controlled drug delivery systems, absorbable sutures (13).

In the electrospinning process, fibers can be produced by applying an electric

potential which provides a charge to the polymeric solution. The charged jet forms nanofibers that can be collected on a stationary or rotating metallic collector (13). (fig. 2).

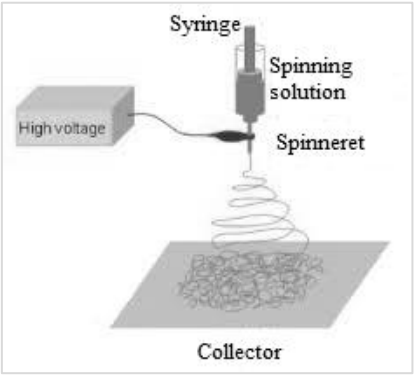

Fig. 2. Electrospinning system

However, this technique attained a considerable recognition since the 90's, when the term electrospinning was invented (14). Polymer solution properties like viscosity, surface tension or conductivity, determine the nanofiber diameter and decrease the risk of bead formation. The nanofibers obtained using this method have gained a particular attention due to their specific properties such as high surface area resulting from the nano- to micro-size, high porosity and good mechanical strength (15). More than this, nanofibers have a high capacity for loading drugs or active materials such as gold (16) or silver nanoparticles (17).

Since bacterial contamination of wounds is a serious problem and a great concern, the selection of a proper antimicrobial agent is essential to inhibit a wide range of pathogens (18). Due to the local interruption of blood flow in burns, systemic infection prevention has low effect, so the use of topical treatment is very important. In the 17th century, silver nitrate was the first silver salt used in the treatment of wounds and ulcers (19). In the prevention process of wound contamination, the use of antimicrobial dressings can help to promote normal wound healing. Lately, a special attention has been given to the preparation of micro- and nanofibrous materials with antibacterial and antifungal activity, as it is the case of antimicrobial nanofibers containing metronidazole (20) or electrospun polycaprolactone containing ampicillin (21).

NATURAL POLYMERS FOR WOUND DRESSINGS

Natural polymers such as collagen, chitosan, elastin, fibrinogen are biocompatible substrates similar to macromolecules recognized by the human body and are involved in the repair of damaged tissues and skin regeneration (22). Also, polymers such as pullulan, dextran, starch, cellulose are used for obtaining electrospun materials with application in the tissue engineering (23).

Pullulan is a linear α-glucane, constituted from three glucose units (fig. 3), being an extracellular microbial polysaccharide produced by the fungus-like yeast *Aureobasidium pullulans*. Several types of nanofibers containing pullulan were prepared using electrospinning technique (24).

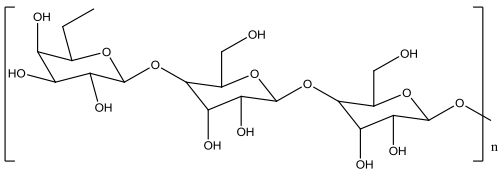

Fig. 3. Structure of *Pullulan*

Dextran is a polysaccharide (fig. 4) with high biocompatibility and biodegradability. It is a proper polymer for development of antimicrobial nanofibers, by up-

loading antimicrobial agents such as moxifloxacin (25).

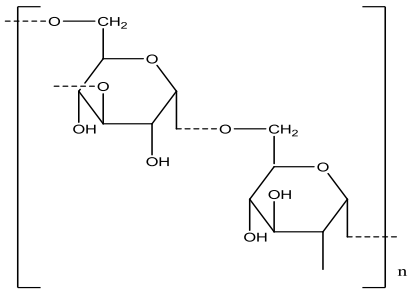

Fig. 4. Structure of *Dextran*

Cellulose (fig. 5) is widely used because of its availability, biocompatibility, degradability and sustainability. It has a large number of applications, from cigarette filters to fibers or films for biomedical fields. It is used especially as healing scaffold for wound dressing (26).

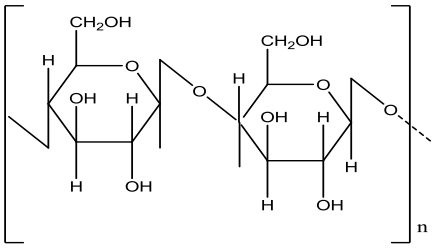

Fig. 5. Structure of *Cellulose*

Chitosan is a naturally derived cationic polysaccharide comprising of N-acetyl glucosamine and D-glucosamine units (fig. 6). Its low toxicity with versatile biological activities such as antimicrobial, low immunogenicity and wound-healing have provided ample opportunities for further development of biomaterials for wound dressing applications (27).

Due to its polycationic nature, chitosan inhibits the growth of a wide variety of bacteria and fungi, showing broad spectra of antibacterial activity, high killing rate and low toxicity (28).

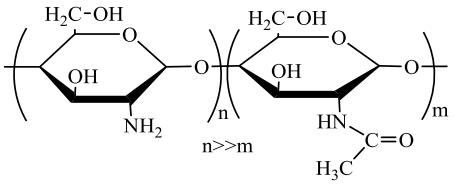

Fig. 6. Structure of *Chitosan*

Carrageenan (fig. 7) is a generic name for a family of polysaccharides, obtained by extraction from some species of red seaweeds (*Rhodophyta*). Carrageenans are widely utilized due to their excellent physical properties such as thickening, gelling and stabilizing abilities (29). Over time, carrageenan was formulated in the form of wound dressings for successful wound healing (30).

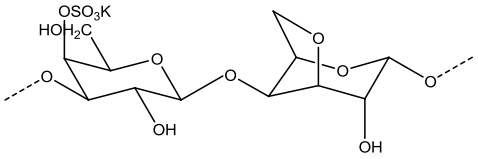

Fig. 7. Structure of *Carrageenan*

SYNTHETIC POLYMERS FOR WOUND DRESSINGS

Nanofibers based on synthetic polymers are prepared by several techniques, especially by electrospinning. Synthetic electrospun scaffolds containing materials such as *poly-caprolactone* (PCL) were found to have good mechanical properties and good biodegradability (31). In addition, other polymers such as *lauric acid*, *polyethyleneglycol*, *polyvinylidene fluoride* have been obtained *via* electrospinning process and the resulting fibers were found to have good mechanical strength and high thermal stability (32).

Poly-(lactic-co-glycolic acid) (PLGA) (fig. 8) is an excellent material for tissue engineering scaffolds because the high surface area allows a high degree of cellular attachment, as well as multiple focal adhesion points on nano-sized fibers (33).

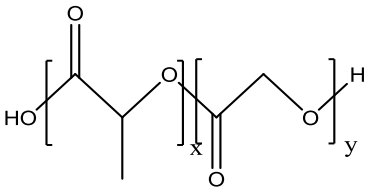

Fig. 8. Structure of *Poly-(lactic-co-glycolic acid)*

Poly-(ethylene-oxid) (PEO) (fig. 9) is a synthetic polymer easy to spin, and has been used for different applications such as drug delivery. Over time, various studies on electrospun PEO/water solutions were aimed at determining the effects of electrospinning process (34).

Fig. 9. Structure of *Poly-(ethylene-oxid)*

Poly-(vinyl alcohol) (PVA) (fig. 10) is a water soluble polymer, nontoxic, biocompatible, biodegradable which has been widely used in biomedical, plastics and textile fields. In the medical field, PVA nanofibrous matrix has been also used for biomimetic wound dressings (35).

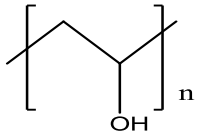

Fig. 10. Structure of *Poly-(vinyl alcohol)*

INFLUENCE OF SOLVENTS ON THE FORMATION OF NANOFIBERS

Solvents used in making polymer solutions are selected on the basis of polymer solubility. Even in these conditions, the solvent with the highest solubility is not always preferable for the electrospinning process. Fluid parameters, like solution surface tension, viscosity, density, conductivity, dielectric constant, are affecting the size and morphology of the electrospun fibers (36).

Some experiments for testing the effect of solvents on the morphology of electrospun polymers have been made. Thus, solvents like acetone, chloroform, dichloromethane, tetrahydrofuran, toluene, hexafluoro-2-propanol, trifluoroethanol have been used to obtain clear polymer solutions to be then processed in nanofibers form (37). The low boiling points of solvents such as of dichloromethane (40^0C) or chloroform (62^0C) determine fast solvent evaporation which leads to porous appearance (fig. 11)

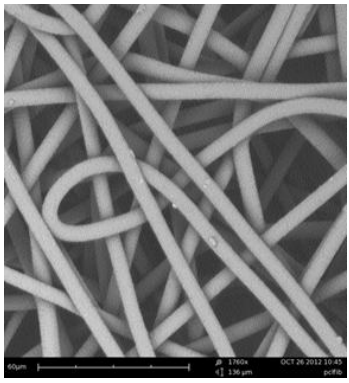

Fig. 11. PCL nanofibers from chloroform

CONCLUSIONS

Based on the complexity of wound healing process it is essential to have an ideal membrane which can combine all the above

mentioned features into one single design, to address the different aspects of a dynamic wound dressing biomaterial. In this context, the use of three-dimensional polymeric scaffolds plays an important role in the treatment of wounds. The attention of researchers, focused on the study of biocompatible and biodegradable natural or synthetic polymers has produced new types of dressings to be used in regenerative medicine. However, for the treatment of burns the most favorable materials are based on natural polymers such as chitosan, dextran or cellulose.

ANTIOXIDANT AND PHYTOBIOLOGICAL STUDIES ON TWO *ALLIUM CEPA* L. EXTRACTS (Abstract). **Aim:** To investigate the antioxidant potential of two *Allium cepa* L. extracts. **Material and methods:** The antioxidant activity of the two extracts (encoded EC1 and EC2) was assessed using two methods: DPPH (2,2-diphenyl-1-picrylhydrazyl) scavenging capacity and determination of their reducing power; phytobiological studies were performed using grains of *Triticum aestivum* L., *Falmura* variety**. Results and discussions:** EC1 and EC2 extracts had a particular affinity for binding DPPH radicals. At equivalent concentrations, the reducing power of EC1extract was about 2 times higher compared to EC2, increasing with the concentration of the analyzed sample. The phytobiological study demonstrated that the investigated extracts had no cytotoxic and genotoxic potential. **Keywords:** ANTIOXIDANT ACTIVITY, *ALLIUM CEPA*, PHYTOBIOLOGICAL

Onion (*Allium cepa* L.) is widely used around the world as a food product, but also for its medicinal applications. Onion contains many active sulfur compounds, mainly cysteine derivatives, as S-alkyl cysteine sulfoxides, which decompose into a variety of thiosulfinates and polysulfides under the action of the enzyme alliinase (1). They possess antidiabetic, antibiotic, hypocholesterolemic, fibrinolytic and other various biological actions. Approximately 90% of the soluble organic bound sulfur is present as γ-glutamylcysteine peptides, which are not substrates for alliinase (2, 3).

Flavonols are present in onion tissues in the form of free quercetin and kaempferol and as the glycosides of those compounds. The main sapogenins from onion are: sitosterol, oleanolic acid, diosgenin, β-chlorogenin and cepagenin (4).

Over time, onion has received a special attention from researchers, who observed its traditional therapeutic uses. Numerous studies have revealed a multitude of biological actions: antibiotic activity (antibacterial and antifungal), action on the cardiovascular system (antiplatelet, lipid lowering), on the respiratory system, antidiabetic, anticancer, antiinflammatory activities (5, 6).

MATERIAL AND METHODS

Extract preparation: Onion extracts

were prepared using fresh bulbs of *Allium cepa* L. (*Wolska* variety) purchased from a local market. The onion bulbs were peeled, cut into small pieces and allowed to stand for 18 h. Then, the product was soaked in absolute ethanol for 10 days at room temperature, with intermittent shaking. The extractive solution was concentrated using a rotary evaporator (under reduced pressure) at 40 °C. The extract encoded EC1 was obtained with a DER (drug extract ratio) of 5:2.

In order to obtain the extract encoded EC2, the onion bulbs were peeled and homogenized in cold water in a blender. The homogenized mixture was filtered through cheesecloth, the filtrate was centrifuged and the clear supernatant was diluted to 100 ml with cold distilled water. The EC2 extract had a DER of 1:2. The aqueous extract was stored at -20°C until use.

DPPH scavenging activity: The scavenging activity was carried out using 2,2-diphenyl-1-picrylhydrazyl (DPPH) free radicals. When a solution of DPPH is mixed with an extract that can donate a hydrogen atom, the reduced form of the DPPH radical is generated, leading to the reduction of the violet color (7). Briefly, 50 µL of sample (EC1 and EC2) was mixed with 2.95 mL DPPH solution (4 mg %). After 5 minutes, the absorbance was recorded at 517 nm using a V-550 Jasco spectrophotometer. Quercetine was used as positive control. The radical scavenging activity was expressed as percentage of inhibition and was calculated as follows:

Scavenging effect (%) = (Absorbance of control-Absorbance of test)/Absorbance of control) X100

Reducing power: The reduction potential of EC1 and EC2 extracts was determined taking into account the fact that substances which act like reducing agents can react with potassium ferricyanide (Fe^{3+}) to form potassium ferrocyanide (Fe^{2+}), which then reacts with ferric chloride to form ferric ferrous complex, that has a maximum of absorption at 700 nm (8). Ascorbic acid was used as positive control.

Phytobiological studies: During our research on EC1 and EC2 extracts, phytobiological studies using grains of *Triticum aestivum* L., *Falmura* variety were performed (9). Three experimental samples (encoded V1, V2 and V3) were used for each set of tests, these representing different concentrations of extract (tab. I).

TABLE I
Experimental samples for phytobiological studies

Treatment	EC1 (mL%)	EC2 (mL%)
Control sample (M)	-	-
V1	1	1
V2	2.5	2.5
V3	5	5

The studied aspects were the influence of EC1 and EC2 extracts on plantlet germination, elongation and biomass accumulation and the impact of the extracts on mitosis in root tissues.

Groups of 200 wheat grains were used for both the control and each dilution; these were soaked for 24 hours in 50 mL of each experimental sample and in the same volume of distilled water for the control. 150 wheat seeds were washed and placed uniformly upon a system made of sieves, with plastic vessels filled with water placed below. The cultivation was performed in an air-conditioned chamber at an average air temperature of 22±2ºC and constant light of 2.500 lux. After 7 days, the germination was stopped, the seed germination rate was

calculated and the shoot and root length was measured. Seedlings having less than 50 mm in length (both root and stem) were excluded from the experiment. Dry weight of roots and shoots for each treatment version was determined, after oven drying at 40 ºC for 24 h.

On day 10 the roots and shoots of the wheat seedlings were detached and weighed. After the determination of their fresh weight (FW) the seedlings were maintained in an oven at 105 ^{0}C for 24 h and weighed again in order to obtain the dry weight (DW). Their average fresh and dry mass was calculated for each experimental sample and also for the control. But, in order to objectively assess to what extent the biostimulatory or bioinhibitory effect was real, the ratio DW/FW x 100 was calculated.

The remaining 50 pre-imbibed grains were placed in 10 cm diameter Petri dishes, on filter paper wet with distilled water. After 72 h, the primary roots were cut off and a squash preparation stained with Schiff reagent was made. Both normal ana- and telophases and those with different types of aberrations (bridges, fragments, fragments and bridges, tri- and tetrapolar anaphases, chromosomes in ring) were counted.

RESULTS AND DISCUSSION

Considering the mechanisms that express the antioxidant activity, the ability to give up a hydrogen atom (or an electron) of the investigated EC1 and EC2 extracts was lower compared to that of 5 mM quercetine, used as control.

Qualitative and quantitative differences concerning the active ingredients with antioxidant potential (flavones, polyphenolic acids, sulfur compounds) present in EC1/EC2 extracts (10) explained why the DPPH scavenger activity was higher for EC1 extract compared to EC2 (fig. 1).

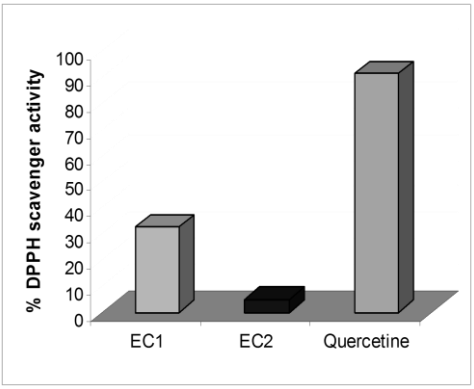

Fig. 1. DPPH scavenging activity of EC1 and EC2 extracts

The increase in absorbance was directly correlated with the reducing power, parameter that can serve as a significant indicator of the antioxidant potential. Data analysis suggested that at the same concentration the investigated extracts had different reducing abilities: at the concentration of 500 mg/mL EC1 extract had a reducing potential equal to that of 6.7 mmol/L ascorbic acid, while the EC2 reducing potential corresponded to that of 3.76 mmol/L ascorbic acid (fig.2).

The experimental data showed a low percentage of inhibition of *Triticum* seed germination for the investigated extracts. The influence of the treatment with onion extracts on the growth of *Triticum aestivum* plantlets was studied by length measurement of roots and shoots (tab. II).

As to the increase in root length, this parameter was generally positively influenced, except for sample V1 for EC1 and EC2 extracts.

The influence of EC1 and EC2 extracts on biomass accumulation is shown in table III.

In the case of EC1 extract, sample V2 caused a slight increase in root biomass accumulation, in both fresh and dried

plants. Fresh and dry shoot biomass accumulation was similar but lower than in the control (fig. 3, 4).

According to the results presented in figs. 3 and 4, it can be stated that the treatment of the caryopses with EC1 and EC2 extracts did not significantly influence the biomass accumulation in the wheat plantlets.

The cytogenetic analysis showed that the frequency of chromosomal aberrations did not exceed 4% for all treatment samples, this value being considered normal for chromosomal aberrations during *in vivo* phytotoxicity testing (fig. 5).

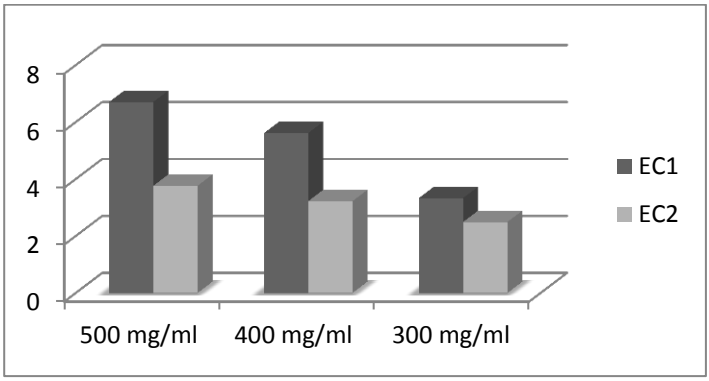

Fig. 2. Reducing power of the investigated extracts

TABLE II

Effect of EC1 and EC2 extracts on germination rate and root and shoot length

Treatment	Sample of treatment	Germination rate %	Root length (mm) ± SD	Shoot length (mm) ± SD
Water	M	93	119.97 ±12.40	149.34 ±12.17
EC1	V1	92	108.55±11.13	144.28 ±14.44
	V2	91	134.07±13.66	146.93±15.28
	V3	85	139.8 ±17.44	148.8 ±15.08
EC2	V1	87	114.76±13.19	146.5 ±14.06
	V2	90	138.8 ±15.19	143.80±16.86
	V3	68	128.2 ±13.82	144.36±12.35

TABLE III

Influence of EC1 and EC2 extracts on biomass accumulation

Treatment	Sample of treatment	Root		Shoot	
		FW (g)	DW (g)	FW (g)	DW (g)
water	M	7.74	0.74	10.62	1.62

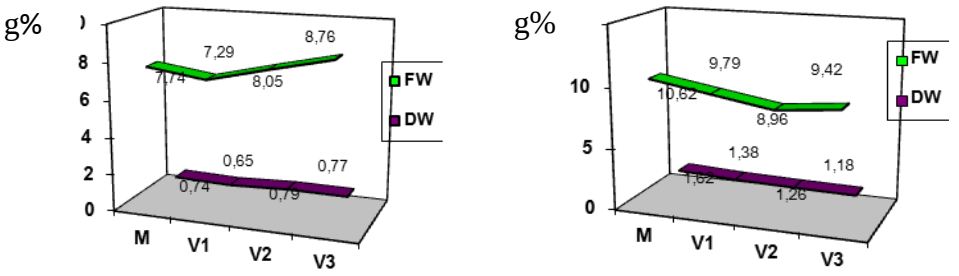
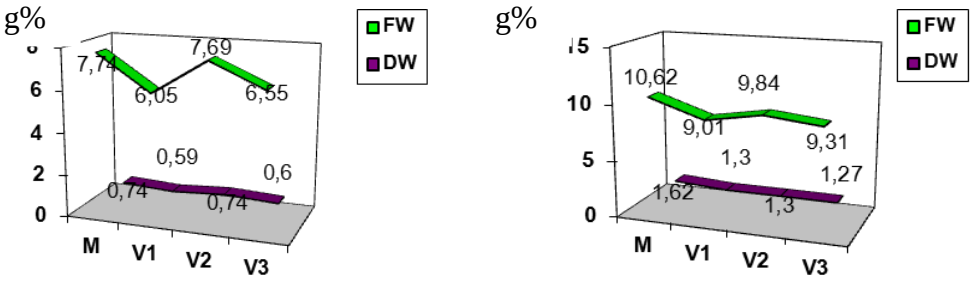
	V2	8.05	0.79	8.96	1.26
	V3	8.76	0.77	9.42	1.18
EC2	V1	6.05	0.59	9.01	1.30
	V2	7.69	0.74	9.84	1.30
	V3	6.55	0.60	9.31	1.27

FW=fresh weight; DW=dried weight



a b

Fig. 3. Fresh and dry biomass accumulation in *Triticum* roots (a) and shoots (b) under EC1 treatment



a b

Fig. 4. Fresh and dry biomass accumulation in *Triticum* roots (a) and shoots (b) under EC2 treatment

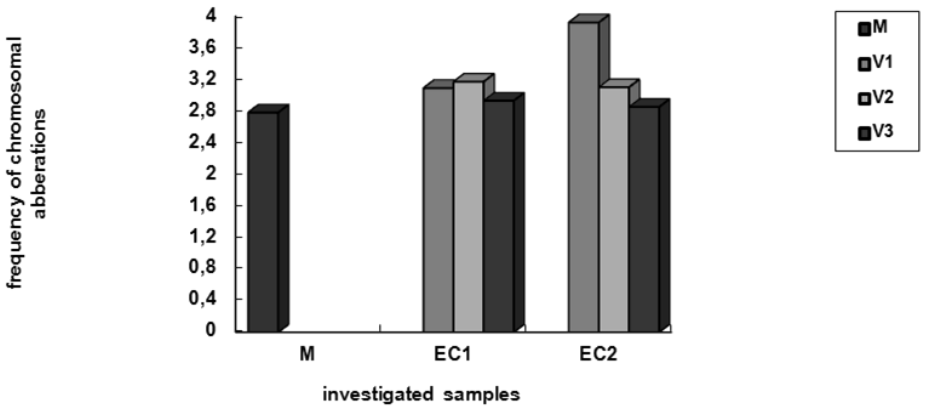


Fig. 5. Frequency of chromosomal aberrations in *Triticum aestivum* root meristem induced by treatment with EC1 and EC2 extracts

CONCLUSIONS

The results revealed that EC1 and EC2 extracts possess an interesting antioxidant activity.

According to the phytobiological studies, the biostimulatory or bioinhibitory

effects of the investigated extracts were not significant compared with the blank.

The results indicated that the extracts were well tolerated by plant cells, revealing the lack of cytotoxicity and mutagenicity.

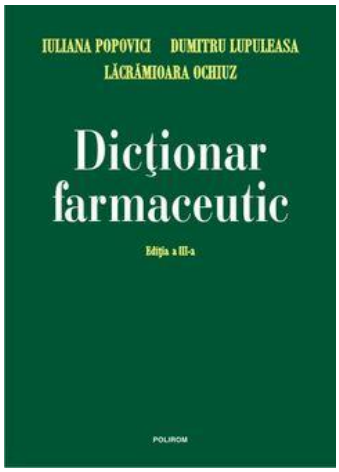
BOOK REVIEW



PHARMACEUTICAL DICTIONARY, Third Edition, 2014

Authors: Iuliana POPOVICI, Dumitru LUPULEASA, Lacramioara OCHIUZ

Preface: Prof. Dr. Medic Valeriu RUSU, member of the Romanian Academy of Medical Science

Publisher: Polirom, Iaşi, BIOS Collection

Description:

The Pharmaceutical Dictionary is a complex work that contains a multi-, inter-, and cross-disciplinary approach that has the purpose of forming and improving the scientific vocabulary of the new generation of pharmacists according to the latest standards of the field. The dictionary contains the latest and most up to date pharmaceutical and medical terminology. Its target audience consists of primarily the students of the Pharmacy and Medicine faculties, but also of pharmacists, physicians, MA graduates, resident physicians, PhD students, scientists working in the cosmetic and pharmaceutical industries, academic personals, researchers on drug development and other professionals working or studying in fields akin to those of medicine and pharmacy.

The third edition of the Pharmaceutical Dictionary has been updated thoroughly and contains eight sections: Introduction; The Evolution of Medical and Pharmaceutical Terminology; Abbreviations; Synonyms and Symbols; Etymologic Guide; Index Terms; Index of Patronyms; Annexes and Bibliography.

The *Dictionary* in Numbers and Figures:

- authors: 3;
- devised with the combined contributions of 45 experts;
- six Universities of Medicine and Pharmacy are represented (Iaşi, Bucureşti, Târgu–Mureş, Timişoara, Arad and Chişinău – Republic of Moldova), as well as pharmaceutic companies;
- it contains:
  - over 18,000 terms;
  - short biographies of over 390 important people in this field;
  - 134 annexes;
  - 126 bibliographic sources;
  - 943 pages.

Contents:

The Pharmaceutical Dictionary contains essential terminology belonging to the fields of analytic chemistry, anatomy, anorganic chemistry, bio-chemistry, bio-pharmacy, bio-informatics, biology, clinical pharmacy, cosmetology, dermopharmacy, environmental and food hygienics, ergonomy, genetics, homeopathy, immunopharmacology, immunology, informatics, inframicrobiology, law,

mathematics, mathematical analysis, medicine, medicine analysis, microbiology, organic chemistry, pathology, parasitology, pharmaceutic bio-technology, pharmaceutical chemistry, pharmaceutical deontology, pharmaceutical marketing and management, pharmaceutical practice, pharmaceutical propaedeutics, pharmaceutical technology, pharmacodynamics, pharmacogenomics, pharmacognosis, pharmacokinetics, pharmacology, physiology, physiopathology, psychology, physics, social pharmacy and patient communication, spectroscopy, statistics, dental medicine, therapy, toxicology, virusology and so on.

Relevant new additions:

- The presentation of the evolution of medical and pharmaceutical terminology;
- The introduction of an etymological guide that explains the origin and composition of each term;
- An explanation of the abbreviations, synonyms and symbols that are frequently encountered in foreign scientific texts;
- The dictionary contains pharmaceutical and medical terms as well as a number of modern words and concepts that are frequently used in other languages; these terms are translated into Romanian and presented in alphabetical order, including their etymology, synonyms, abbreviations and definitions;
- An alphabetical list of patronyms – the most important and influent people in the history of medical and pharmaceutical sciences since antiquity to this day;
- An impressive number of annexes, grouped into eight sections, in tables containing exact or suggestive data, towards ensuring clear and accurate explanations for any pharmacist;
- The most recent and relevant bibliography and sources.

As noted by Prof. Dr. Valeriu Rusu in the preface of the *Pharmaceutical Dictionary*, the current context of international cooperation, built on the constant change of information and the continuous advancement of knowledge, urges any professional who strongly desires a career in the vast field of medicine to always be kept updated with the most recent developments in his or her field of practice. This makes the *Dictionary* a most important asset in the formation of any such professional.

PROTECTIVE EFFECT OF GRAPE SEED EXTRACT IN EXPERIMENTAL MENOPAUSAL SYNDROME

PROTECTIVE EFFECT OF GRAPE SEED EXTRACT IN EXPERIMENTAL MENOPAUSAL SYNDROME (Abstract) Grape seed extract (GSE) is a natural product obtained from *Vitis vinifera* seeds; it has been used as adjuvant therapy in wide range of pathological conditions. **Aim:** In the present study, we investigated the ability of GSE to improve the mental status on ovariectomized rats. **Material and methods**: GSE (10 mg/kg/day, 60 days long) was administrated orally on ovariectomized adult female rats; then the animals were investigated in open field. Additionally, were measured the hematological parameters, the plasma biochemistry, and the oxidative stress markers. **Results and discussion**: Treatment of GSE improved the loco motor activity in the open field, the number of crossings were almost twice in GSE treated rats (22.25±8.75) compared to placebo group (13.00±2.62) ($p<0.05$). Lipid peroxides were reduced up to 51.57% ($p<0.05$), while hematology and plasma biochemistry remained almost unchanged. **Conclusion:** GSE improve the mental status and reduced the level of oxidative stress in rats subject to experimental ovariectomy. **Keywords:** POLYPHENOLS, OXIDATIVE STRESS, OVARIECTOMY, OPEN FIELD

Menopause is the cessation of spontaneous menstrual cycling; the average age of menopause in women is approximately 50 years, resulting a post reproductive period for one third of their lives. A number of other physiological systems are also affected by the sudden withdrawal of hormonal support associated with menopause, including bone density, cardiovascular health, cognition and possibly some cancers. Finding an appropriate model is a debated subject, but the use of rodent models is manifold, because they have a relatively low life span, ovarian function is well characterized and homogenous laboratory strains allowed controlled experiments (1). This experimental model is widely used to prove the efficiency of various plant compounds against menopause associated pathology; polyphenols from green tea proved to have a protective effect against bone loss in on ovariectomized female rats in non dose dependent manner, the same osteprotective effect was provided by phytoestrogens like coumestrol and zearalanol (2); on the other hand, soy isoflavone prevent oxidative changes in hepatocytes (3) and flavones from *Radix puerariae* reduce the hepatic

accumulation of triglycerides (4).

Grape seed extract (GSE) is a natural product obtained from *Vitis vinifera* seeds; and they are a byproduct of wine. Nowadays, the interest for GSE is fully justified, they contain polyphenols, mainly flavonoids, proanthocyanidins, galic acid, cathechins etc. The most important constituents are the polyphenoles, which act not only as effective free radical scavenges, but they modulate de activity of antioxidant enzymes, block hormone receptors, and reduced the activity of various mutagens. Experimental and clinical studies show that polyphenols protect the blood vessel, prevent the platelet aggregation, and lower the LDL-cholesterol.

MATERIAL AND METHODS

Nutritive supplement. Grape seed extract (GSE) was a commercial capsulated product 100 mg / capsule, a generous gift of TC Alsifcom Ltd. The hydro soluble premix (extracted with hydro alcoholic solutions), was manufactured by Eurochem Feinchemie GmbH (batch number 4001103K001). The analysis bulletin was performed by high performance liquid chromatography (HPLC); its composition was as follow catechins 2-3%, epicatechins 2-3 %, proanthocyanidin oligomers (bi- and trimetric) 6-9%, proanthocyanidin (polymers) 89 %, total of proanthocyanidin oligomers were over 92%. The product was within acceptable range of microbiological contamination and residues. The animals in study received 10 mg/kg/day, dissolved in water, immediately before administration, for all experiment long.

Animals. Experiments and animals welfare were according to the *Guide for the Care and Use of Laboratory Animals* (Department of Health Education, and Welfare, National Institute of Health, 1996), and followed the guidelines of European Communities Council Directive (86/609/1986) and Ordinance No. 37 of the Romanian Government from 2nd February 2002. The animal tests and experiments were allowed by the Bioethical Board of the Faculty of Veterinary Medicine Cluj-Napoca. The animals were caged in polycarbonate cages, at controlled temperature of 21-22ºC, humidity (40-60%) and 12/12h light/dark cycle. Standard lab chow, soy free (to avoid any source of estrogens), provided by National Institute for Research and Development Cantacuzino Bucharest, and water were freely available.

Experimental protocol. Experiment was carried out on 24 albino Wistar female rats, 232.75±8.52 g body weight, divided into tree equal groups, of 8 animals each. Groups I was the sham operated group, it represents the control. Groups II and III were subject to ovariectomy, and, additionally, 5 days after surgery, group 3 received GSE therapies orally, by using a lubricated catheter, daily, for 60 days long, until the end of the study. The other two groups received isotonic saline solution as placebo. In the end, the animals were subject to open field test; blood samples were drawn under deep narcosis and, than, euthanasia was made. Immediate latter, the animals were subject to gross examination and uterus weight was determined.

Surgical procedure. The surgery was performed under isoflurane narcosis, supplemented by neuroleptanalgesia by xylazine 0.2% (Narcoxyl) 0.2 ml/kg and ketamin 10% 0.3 ml/kg injected intramuscularly. A longitudinal incision was made along vetromedian area, between umbilical region and pubis; the ovaries were exteriorized, and excised. Abdominal muscles and skin were sutured with Dexon and polyacrilate respectively. The sham operated

animals were subject to laparotomy, but whiteout removal of the ovaries. The subjects were allowed 5 days to recover from surgery before starting the experiments.

Open Field Test. Open field test was run within in a box measuring 60x40x50 cm, whose floor was divided by lines into 12 equal squares. Animals were placed facing the rear left corner of the arena and observed for 3 min. Number of squares crossed with the four paws from one square to another was indicative of motor activity. Measuring score included defecation, urination and ambulations.

Laboratory analysis. Blood hematology was investigated immediately, using EDTA anticoagulated blood, with Abacus Junior Vet, automatic analyzer Diatron Messtechnik, Budapest, Hungary. For biochemical analysis, the blood drawn in clot activator vacutainers, was centrifuged at 2000 rpm for 10 min to separate the serum, immediately after separation serum samples were frozen at – 20 ºC. Blood chemistry (cholesterol, triglyceride, alkaline phosphatase etc.) was measured using screen point semiautomatic analyzer, STAT – FAX 1904 Plus, Global Medical Instrumentation, Inc. 6511 Bunker Lake Blvd. Ramsey Minnesota, 55303 USA, by using special determination kits.

Lipid peroxides were determined, by measuring the production of tiobarbituric reactive substances according to the method of Burge and Aust, protein carbonyl were evaluated by using guanidine chloride. Ravin method (parafenildiamin dichloride) was the choice for measuring the plasma ceruloplasmin, while Hatano (diphenyl picrichydroxil) method was preferred for measuring hydrogen donor ability.

Statistics. All data are reported as the mean ± SEM. The Gaussian distribution was checked by Shapiro-Wilk normality test. One-way analysis of variance ANOVA, followed by post hoc Dunnett's range test procedure was done Statistical significance was at $p<0.05$ (95% confidence interval). Statistical values were obtained using GraphPad Prism version 5.0 for Windows, GraphPad Software, San Diego California USA.

RESULTS AND DISCUSSION

The mean body mass increased significantly in both ovariectomized groups (II and III) compared to group I ($p<0.05$), body weight gain was associated with high amount of abdominal fat. Increasing in body weight and abdominal fat accumulation is a widely accepted side effect of ovariectomy as a consequence of sudden drop in estrogen level (4). Expectedly, the uteri of rats from groups II and III revealed severe atrophy, highly significant as compared to group I ($p<0.001$). GSE therapy has no influence the body weight or the degree of uterus involution, therefore GSE does not seem to exert any estrogenic effect on the genital organs or other body areas (tab. I).

TABLE I

Variation of body weight and uterus weight

	b.w. initial (g)	*b.w. final (g)*	*dif b.w..*	*Uterus*	*% of b.w..*
Control	215.20±18.09	225.00±28.78	09.80 ±27.10	0.700±0.200	0.310±0.080
Ovariectomy	248.75±05.30	286.50±17.67	37.75*±12.37	0.195±0.007**	0.068±0.006*
Ovariectomy +GSE	177.33+11.45	222.83+13.24	45.50+21.54	0.180+0.070	0.081+0.033

Result expressed as mean ± SD, b.w. = body .weight. GSE = Grape seed extract

* and ** = statistically significant as compared to Control group at $p<0.05$ and $p<0.001$

Oxidative stress markers were increased following ovariectomy, but significant results we found only for malonildialdehyde ($p<0.05$). The therapy was effective, the values in group III were significant lower than in group II ($p<0.05$), and they were similar to group I rats. In menopausal women, is already proved a clear relationship between the plasma levels of malonildialdehyde and the logarithm of the plasma estradiol concentrations, which was best demonstrated with a quadratic regression (5), estrogens having a well known antioxidant protective effect. The antioxidant protective effect of GSE is not surprising; it was already proved on various experimental models (tab. II).

TABLE II

Variation of oxidative stress markers

	Malonildialdehyde (nmol/ml)	Protein carbonyl (nmol/ml)	Hydrogen donors ability (%)
Control	5.8±1.74	1.54±0.76	31.06±6.95
Ovariectomy	11.13±2.95*	1.20±0.35	34.66±10.13
Ovariectomy +GSE	5.74±1.29†	0.80±0.15	28.24±8.66

Result expressed as mean ± SD, GSE = grape seed extract

* = statistically significant as compared to Control group at $p<0.05$

† = statistically significant as compared to Ovariectomy group at $p<0.05$

Plasma biochemistry showed increase serum alkaline phosphatase (AP) activity in both groups II and III (184.7±73.5 u/l, and 164.7±53.3 u/l, respectively) as compared to I (137.8±37.2 u/l,) ($p<0.05$). The relation between the loss of bone density and elevated activity for AP is widely accepted; so, antiosteoporotic therapy also down regulates the AP activity (2). Similar values of PA between groups II and III suggest that GSE failed to prevent the bone destruction. Other blood enzymes (GGT, ASAT and ALAT) reveal no difference among groups in study, so were the other biochemical compounds (triglycerides, cholesterol, urea, creatinine, glucose, total bilirubin, total protein, and calcium). Hematology was also, within normal limits for all groups. In female Guinea pigs, subject of ovariectomy and a high cholesterol diet, the GSE supplementation reduced the plasma triglycerides. Even that cholesterol levels remained high, the VLDL cholesterol was diminished, and, by down regulation of cholesterol acyle transferase, GSE prevents the cholesterol accumulation into the aortic walls (6). Furthermore, GSE proanthocyanidins prevent the posprandial peroxidation of lipids, and peroxidation of LDL (7). Clinical studies also confirm the protective effect of GSE against menopausal associated dyslipidemia; it reduced the plasma triglycerides and LDL, by diminishing the systemic inflammatory status and oxidative stress (8). In our findings, the ovariectomy was not associated with any obvious impairment of excretory, liver or metabolic function, probably because the animals received a balanced diet, whiteout atherogenic compounds, which unrevealed a possible protective effect of GSE on lipid metabolism. Our findings correlated to literature data, suggest once again that, in addition to hormonal imbalance, dyslipidemia associated with menopausal syndrome have an important alimentary etiology.

TABLE III
Results of the *Open field* test

	N. of rearing	No.of defecations	No.of crossings
Control	7.75±2.92	3.13±1.13	27.00±7.45
Ovariectomy	2.87±1.55††	0.75±0.89††	13.00±2.62††
Ovariectomy +GSE	5.00±4.30	6.25±2.65** †	22.25±8.75*

Result expressed as mean ± SD, GSE = grape seed extract
* and ** = statistically significant as compared to *Ovariectomy* group at $p<0.05$ and $p<0.01$
† and †† = statistically significant as compared to *Control* group at $p<0.05$ and $p<0.01$

Ovariectomy was responsible for reducing the motility, reflected in number of rears, in squares crossings and also the emotive expressed in defecations ($p<0.01$). It not a widely accepted opinion that ovariectomy is able to induce the decreasing of motility, Monteiro, *et al*. (9) assumed that ovariectomy did not affect the number of crossings, but other studies, relate the response to open field test to number hormonal status (10). However, the GSE proved a significant ameliorative effect, the number of defecations and crossings were improved in a significant manner ($p<0.05$), and distinctly significant manner ($p<0.01$) respectively.

Even various plant compounds have antidepressant properties; relatively few studies on GSE were done. Therefore, the mechanism remain obscure, but is rational to suppose that this improvement in mental status is subsidiary to general tonic effect provided by the plant compounds, because clinical evaluation revealed a much better condition in treated animals as compared to other groups, including sham operated animals.

In post menopausal women, the impairment of cognitive functions is not only induced by the estrogenic withdrawal, but also with degenerative phenomena inherent to aging process, many related to increased oxidative damage. Diminished efficiency of brain antioxidant systems in elderly rats leads to an intense formation of lipids peroxides (11, 12), carbonyl proteins, reduction of total donor hydrogen ability (11), functional impairment of cholinergic system (12), and consequently, loss of memory (11). GSE prevents, to some extent, these side effects of aging, not as a simple antioxidant only, but as an inductor of the antioxidant enzymes CAT and SOD (12). The inductor mechanism of GSE was further proved on gene expression of antioxidant enzymes *in vitro*, on HepG2 hepatocarcinoma cell line (13).

CONCLUSIONS

On rat ovariectomy model, GSE prevented the plasma lipid peroxidation and improved the cognitive functions, but it did not affect the level of uterine involution and the body weight gain. These findings recommend it as possible alternative remedy against menopausal associated pathology.

ANTIOXIDANT ACTIVITIES AND PHENOLIC CONTENTS OF EXTRACTS FROM *GLINUS OPPOSITIFOLIUS* AERIAL PARTS (Abstract): In Malian traditional medicine, aerial parts of *Glinus oppositifolius* are used in the treatment of many disorders, particularly inflammations and joint pains. **Aim**: The present study was initiated to investigate the antioxidant potential of *Glinus oppositifolius*. **Material and methods**: Aqueous and ethanol extracts were prepared from the dried aerial parts. Both extracts were examined for the phenolic content and antioxidant activity. Total phenolic content was quantified by Folin-Ciocalteu method. Antioxidant activity was studied *in vitro* by evaluating the ability to scavenge different free radicals (ABTS, superoxide and hydroxyl radicals, nitric oxide) and to chelate ferrous ions. **Results**: Aqueous extract was found to contain a higher level of total phenols than ethanol extract (1.27±0.04 *vs.* 0.94±0.05 g GAE/100 g extract). Both extracts lacked the ability to scavenge superoxide anion radical but scavenged ABTS and hydroxyl radicals, nitric oxide and chelated ferrous ions in a concentration-dependent manner. According to the EC_{50} values, aqueous extract showed stronger antioxidant effects than ethanol extract (174.32±1.49 *vs.* 276.76±1.52 µg/mL in ABTS radical cation scavenging assay, 119.91±1.70 *vs.* 240.57±0.97 µg/mL in nitric oxide scavenging assay, 1.99±0.01 *vs.* 6.54±0.08 mg/mL in ferrous ion chelating assay). In hydroxyl radical scavenging assay, aqueous extract had an EC_{50} value of 0.86±0.00 mg/mL while the EC_{50} value of ethanol extract was higher than the highest concentration that was tested (3.75 mg/mL). **Conclusions**: Our results clearly indicate the antioxidant potential of *Glinus oppositifolius* aerial parts and suggest that the anti-inflammatory activity might be partly related to the antioxidant potential. **Keywords**: *Glinus oppositifolius*, INFLAMMATION, OXIDATIVE STRESS, FREE RADICAL SCAVENGING ACTIVITY, FERROUS ION CHELATING ACTIVITY

Glinus oppositifolius (L.) Aug. DC. (*Aizoaceae*) is native to tropical and subtropical regions of the world, its leaves and aerial parts being used either as food or medicine in different ailments. In Malian traditional medicine the plant has been used in the treatment of joint pains, inflammations, fever, skin disorders, wounds, urinary

infections, abdominal pains, diarrhoea, intestinal parasitosis, malaria. In an attempt to valorize Malian traditional medicines, researchers from School of Pharmacy, University of Oslo and Department of Traditional Medicine, Bamako, Mali carried out chemical and biological studies on the aerial parts of the species. Triterpenoid saponins and pectic polysaccharides have been isolated and characterized. Pectic polysaccharides showed immuno-modulating activity by fixing the complement system components and increasing the chemotaxis of macrophages, NK cells and T cells (1-3).

Glinus oppositifolius is one of the herbs Malian traditional healers use in the treatment of inflammations and joint pains. In addition to an enhanced immune response, inflammation is characterized by an increased oxidative stress (4, 5). The aim of the present study was to evaluate a possible antioxidant activity involved in the anti-inflammatory potential of *Glinus oppositifolius*. In this respect, the antioxidant activity of aqueous and ethanol extracts was studied by evaluating their ability to scavenge free radicals and to chelate ferrous ions. The total phenolic content was also determined.

MATERIAL AND METHODS

Chemicals.

Tris(hydroxymethyl)aminomethane (Tris), ferrous chloride, sodium nitroprusside were purchased from Merck (Darmstadt, Germany). 2, 2'-Azinobis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt (ABTS), ethylenediaminetetraacetic acid (EDTA), 3-(2-pyridyl)-5,6-diphenyl-1,2,4-triazine-4',4''-disulphonic acid monosodium salt (ferrozine), glutathione, pyrogallol, Folin-Ciocalteu's phenol reagent were supplied by Fluka (Steinheim, Germany). Iron (II) sulfate heptahydrate, hydrogen peroxide, L-ascorbic acid, N-(1-naphtyl) ethylenediamine dihydrochloride, sodium salicylate, sulfanilamide, were obtained from Sigma-Aldrich Chemie GmbH (Steinheim, Germany). Gallic acid monohydrate and potassium persulphate were purchased from Riedel-de Haën (Seelze, Germany).

Plant material. Aerial parts of *Glinus oppositifolius* (L.) Aug. DC. were supplied by the Department of Traditional Medicine, Bamako, Mali where a voucher specimen is deposited.

Extraction. Dried and powdered aerial parts (100 g) were refluxed with 2 × 2 L ultrapure water at 50°C, each time for 4 h or extracted by stirring with 2 × 2 L ethanol at room temperature, each time for 72 h. The combined aqueous and ethanol extracts were concentrated under reduced pressure at 50°C (Büchi R-210 rotary evaporator, Büchi V-850 vacuum controller, Büchi V-700 vacuum pump, Büchi B-490 heating bath) and then freeze-dried (Unicryo TFD 5505 freeze-dryer).

Total phenolic content. Total phenolic content was estimated by Folin-Ciocalteu method (6). The results were expressed as g gallic acid equivalents (GAE)/100 g extract.

ABTS radical cation scavenging assay. ABTS assay was performed according to the method developed by Re *et al*. (7). Glutathione was the positive control.

Superoxide anion radical scavenging assay. The assay was performed as described by Wang and Luo (8). Glutathione was used as positive control.

Hydroxyl radical scavenging assay. The assay was done according to the method described by Jeong *et al.* (9). L-Ascorbic

acid was used as positive control.

Nitric oxide scavenging assay. The assay was performed as reported by Tsai *et al.* with minor changes (10). L-Ascorbic acid was the positive control.

Ferrous ion chelating ability assay. The assay was done according to Dinis *et al.* (11). EDTA was used as positive control.

Statistical analysis. All experiments were performed in triplicate. The results were expressed as means±standard deviations. The EC_{50} values were calculated by linear interpolation between values above and below 50% activity.

RESULTS

Extraction. After removing the solvents, 40 g aqueous extract (GA) and 23.7 g ethanol extract (GE) were obtained.

Total phenolic content. The total phenolic contents of GA and GE were found to be 1.27±0.04 and 0.94±0.05 g GAE/100 g, respectively.

ABTS radical cation scavenging assay. Both extracts scavenged ABTS radical cation in a concentration dependent-manner. At 100 µg/mL, GA and GE showed scavenging effects of 35.42±0.47 and 27.37±0.66%, respectively. At 400 µg/mL, the scavenging activity of GA and GE increased significantly to 73.75±0.15 and 65.12±1.01%, respectively. Within the same concentration range (100-400 µg/mL), glutathione completely scavenged the radical (99.47±0.29-99.68±0.02%) (fig. 1). According to the EC_{50} values, the abilities to scavenge ABTS radical cation varied as follows: glutathione > GA > GE (tab. I).

Superoxide anion radical scavenging assay. Within this assay, GA and GE showed no scavenging effects on superoxide anion radical.

Hydroxyl radical scavenging assay. GA showed a higher hydroxyl radical scavenging activity than GE. At the highest concentration tested (3.75 mg/mL), GA scavenged the radical in a percentage of 91.69±0.09% while GE showed only 31.33±0.74% scavenging activity. GA was less active than the positive control, L-ascorbic acid; at concentrations of 0.47-3.75 mg/mL, the latter exhibited 100% scavenging activity (fig. 2). With regard to the EC_{50} values, the hydroxyl radical scavenging activity decreased as follows: L-ascorbic acid > GA > GE (tab. I).

Nitric oxide scavenging assay. Both extracts showed dose-dependent nitric oxide scavenging effects. The scavenging activity of GA increased significantly from 42.10±0.57% at 83.33 µg/mL to 83.47±0.17% at 1333.36 µg/mL. At the same concentrations, GE exhibited scavenging effects of 22.37±0.70 and 86.59±0.46%, respectively. The effects of L-ascorbic acid were superior to those of GA and GE at all concentrations tested (fig. 3). According to the EC_{50} values, the nitric oxide scavenging effects decreased in the following order: L-ascorbic acid > GA > GE (tab. I).

Ferrous ion chelating ability assay. Ferrous ion chelating abilities of both extracts increased with concentration. At all concentrations tested, the chelating ability of GA was greater than that of GE but lower than that of EDTA. At the highest concentration tested (6.62 mg/mL), the chelating effects of GA and GE were 76.53±0.48 and 50.40±0.75%, respectively; at the same concentration, EDTA completely chelated the ferrous ions (fig. 4). The ferrous ion chelating ability decreased as follows: EDTA > GA > GE (tab. I).

DISCUSSION

Numerous studies have reported the involvement of reactive oxygen species in inflammation. After infiltration to the inflammatory site, polymorphonuclear leukocytes and macrophages release high levels of superoxide anion radical and hydrogen peroxide (respiratory burst). Superoxide anion radical is able to release iron from ferritin as ferrous ions. Ferrous ions promote the generation of hydroxyl radical *via* Fenton reaction. Hydroxyl radical is the most aggressive reactive oxygen species being responsible for protein, lipid and DNA damage (4, 5, 12). In inflammation, inducible nitric oxide synthase (iNOS) generates high levels of nitric oxide. Nitric oxide enhances the production of pro-inflammatory cytokines such as tumor necrosis factor alpha (TNFα), interleukin-1β (IL-1β), but also of collagenases thus promoting the progression of inflammation (12). Nitric oxide in excess generates enhanced levels of reactive nitrogen species which target cellular macromolecules causing additional tissue damage (10).

This study indicated that *Glinus oppositifolius* extracts have antioxidant activity. GA and GE scavenged free radicals such as hydroxyl radical and nitric oxide and chelated ferrous ions. GA was found to be more active than GE. The stronger antioxidant activity of GA cannot be justified solely by its higher phenolic content; other

phytochemicals may also contribute to the antioxidant potential of GA. GA scavenged hydroxyl radicals and chelated ferrous ions with EC_{50} values of 0.86±0.00 and 1.99±0.01 mg/mL, respectively; in the same assays, GE showed weaker effects (EC_{50} > 3.75 mg/mL, EC_{50} = 6.54±0.08 mg/mL). In nitric oxide scavenging assay, GA (EC_{50} = 119.91±1.70 µg/mL) was only 2.6 times less active than L-ascorbic acid (EC_{50} = 45.46±0.45 µg/mL). As L-ascorbic acid is a strong nitric oxide scavenger (13), it is obvious that GA exhibited a very good scavenging activity. The high scavenging activity against nitric oxide, the ability to eliminate hydroxyl radicals and chelate ferrous ions make GA a good candidate for *in vivo* studies. Neither GA nor GE scavenged superoxide anion radicals. The lack of superoxide scavenging effects is surprising given that both extracts scavenged other free radicals. It is possible that certain phytochemicals in extracts act as prooxidants under the conditions of this assay thus masking the superoxide scavenging activity. It is worthy to note that there have already been reported prooxidant effects for certain flavonoids, alpha-tocopherol, coenzyme Q10, clove essential oil and butylated hydroxytoluene when tested in this assay (14, 15).

CONCLUSIONS

It can be concluded that the anti-inflammatory potential of *Glinus oppositifolius* is partly related to its antioxidant properties.

Further studies are needed to evaluate the *in vivo* significance of the antioxidant activity and its role in the regression of inflammation.

NEWS

CEREBROPROTECTIVE EFFECTS OF IBUPROFEN ON DIABETIC ENCEPHALOPATHY IN RATS

A group of researchers from Xuzhou Medical College and Nanjing General Hospital of Nanjing Military Command, Jiangsu, China investigated the effects of ibuprofen on diabetic encephalopathy and the potential mechanisms. Diabetes was induced through a single intraperitoneal injection of streptozotocin (60 mg/kg). The diabetic rats were randomly divided into two groups: the control and the treated groups. The treatment was initiated 7 days after induction of diabetes and consisted in oral administration of ibuprofen (40 mg/kg) for 8 weeks. Cognitive performances were evaluated using Morris water maze. The temporal cortex and hippocampus were obtained to evaluate the levels of advanced glycation endproducts (AGEs) and their receptor (RAGE), the activity, protein expression, and mRNA levels of β-amyloid precursor protein cleaving enzyme 1 (BACE1), the protein and mRNA expression of peroxisome proliferator-activated receptor γ (PPARγ), and the protein expression of cyclooxygenase 2 (COX-2) and inducible nitric oxide synthase (iNOS). Blood was obtained for the evaluation of interleukin 1β level. The research revealed that chronic ibuprofen treatment reduced the mean escape latency of diabetic animals and significantly prevented the decline in learning and memory ability of diabetic rats. Ibuprofen treatment recovered the enzymatic activity of BACE1 to the control level in the temporal cortex, while markedly reduced enzymatic activity in the hippocampus of diabetic rats. Moreover, ibuprofen treatment reduced the activity, protein, and mRNA levels of AGE level, protein expression of RAGE, COX-2, and iNOS in the brain, and interleukin 1β level in serum, while increasing the protein and mRNA expression of PPARγ in the brain of diabetic rats. The present study demonstrated that ibuprofen ameliorated diabetic encephalopathy caused by type 1-diabetes, as evidenced by the improvement of cognitive dysfunction and the loss of neurons in the hippocampus. Furthermore, the amelioration of diabetic encephalopathy by ibuprofen was achieved by the down-regulation of BACE1, the suppression of the AGE/RAGE axis and inflammation in the brains of diabetic rats. (Liu Y-W, Zhu X, Zhang L, Lua Q, Zhang F, Guoa H, Yin X-X, Cerebroprotective effects of ibuprofen on diabetic encephalopathy in rats. *Pharmacol Biochem Behav* 2014; 117: 128-136)

FUNCTIONAL ANATOMY OF THE TEMPORO-MANDIBULAR JOINT (II) (Abstract): Jaw movement is analyzed as an action between two rigid components jointed together in a particular way, the movable mandible against the stabilized cranium. Opening and closing movements are symmetrical; that is, both sides of the cranio-mandibular articulation are making the same movements. Protrusive and retrusive movements may also be symmetrical. The mandibular muscles determine all the complicated postures and movements of the jaw. Their behavior can be greatly clarified by restating certain fundamentals crucial to purposive muscular activity. The joint derives its arterial supply from the superficial temporal artery and the maxillary artery. Branches of the auriculo-temporal and masseteric nerves and post-ganglionic sympathetic nerves supply the tissues associated with the capsular ligament and the looser posterior bilaminar extension of the disc. **Keywords**: TEMPORO-MANDIBULAR JOINT, JAW MUSCLES, POSTURES, MOVEMENTS, MANDIBLE.

Physicists point out that the most general type of motion a body can undergo is a combination of translation and rotation (1). Translation is defined as a motion in which all points of a rigid body move in the same direction with the same velocity, at any given instant, relative to the same point outside the body. Rotation is a motion in which some points of a rigid body move in one direction while other points move in the opposite direction, at any given instant.

Now it can be readily seen that a partially lowered mandible can translate, that is, more forward or backward over the articular eminence with all points of the jaw moving in the same direction at the same rate, at any given instant. Thus in simple lowering and rising of the mandible, the definitive statement must be that the condyle rotates relative to the disc while the disc is rotating relative to the articular eminence with concurrent translation of the mandible relative to the temporal articular faces. It is simply a problem of relative motion, and mandibular movements are completely consistent with the general observations in the physics of motion (2).

MOVEMENTS

Opening and closing movements are symmetrical; that is, both sides of the cranio-mandibular articulation are making the same movements. Protrusive and retrusive movements may also be symmetrical. In this case disc and condyles of both sides slide downward and forward and backward

and upward, respectively, with condyles and discs always, as in all joints of the body, in firm contact with their opposing articular surfaces. Movements may also be executed asymmetrically, which then produces a lateral movement, a swinging of the jaw to one side. In this case one disc, accompanied by its condyle, slides downward, forward, and medially on to the preglenoid and medial glenoid planes.

The disc and condyle on the side to which the jaw is moving (left condyle for left lateral movement) do not travel far from their starting positions on the posterior slope of the eminence. Here the condyle orbits very slightly downward then outward in a small arc around a vertical axis somewhere behind the condyle. This imparts a transverse component to the excursion and thus produces a direct lateral shift of the entire mandible to the chewing side. This has been called the Bennett movement, or Bennett shift, and although it may be slight (probably never more than 1.5 mm) it has been considered significant in certain cases of restorative and prosthetic dentistry (2).

The lower joints of both sides work together as a common hinge joint. The two discs are the sockets, or „hooks", of the hinges, and each condyle forms the bar in the eye of the hinge on which the jaws swings open and closed. Because of the notable obliquity of the condyles to the frontal plane - the condylar axes converge posteriorly - the hinge movement of the mandible must be accompanied by adjusting movements between condyles and discs. The hinge movement occurs around a horizontal axe that runs approximately through the centers of the two condyles. Thus, during opening, the lateral pole of each condyle, situated in front of the hinge axis, must move slightly downward and backward. Concomitantly, the medial poles, situated behind the hinge axis, must move slightly upward and forward.

This information is highly significant clinically in radiographic interpretation. Ignorance of these anatomic facts has resulted in the belief that condyle and eminence does lose contact (separate) during normal jaw movements, since a dense lateral pole is seen radiographically to move away from the eminence. But, as pointed out previously, areas of articular contact are constantly shifting during movement in all joints of the body; thus contact is shifting toward the medial pole in simple opening. This prevents concentration of pressure at any point for any length of time (3). The broad areas of the close-packed position are adapted to withstand the peak of functional pressure.

Under normal conditions, sliding in the upper joints and rotating in the lower joints are probably always combined, but the magnitude of one or the other at a given time varies considerably. Both mandibular joints, always working together as a functional unit, can be classified as a hinge joint with a sliding socket (4). This definition clarifies the proper role or functional significance of the articular discs; they comprise the movable sockets of the hinge joint between the condyles and discs. The combination of two joints on the each side of the jaw gives a certain freedom of movement to the mandible in all planes of the space. But the fact that the articulating components always work in close contact obviously imposes some limitation of movement because of the two-sided articulation. Furthermore, the magnitude of these movements in not great, since they are effective limited by all the various fibers of the temporo-mandibular ligaments of each

side in the opened positions, to which is added the contact of the tooth plates in terminal closing positions.

RANGE OF MOVEMENTS

Beginning with the condyles retruded to the extreme hinge position, the mandible can perform a theoretically pure hinge rotation about a fixed axis passing through the approximate centers of both condyles. In opening, the interdental point swings down in an even arc of about 20 to 25 mm in length. Further opening requires a downward and forward excursion of condyles and discs along the articular eminences, with continued rotation of the condyles within the lower joint compartments. This activity within the joint abruptly changes the course of the incisal point. It then proceeds in an arc of greater curvature directed more anteriorly, in which the lower termination marks the limit of greatest jaw opening.

From this point closing proceeds directly upward and forward with the mandible strained forward in maximal protrusion during its entire path of movement. The interdental point now describes an arc of the least curvature in the sequence. Its upper termination is brought about by contact of the posterior teeth, since the lower anteriors reach forward beyond the upper anteriors with the jaw in its most protruted position. In making this movement, the condyles rotate backward in the lower compartments, and both condyles and discs move slightly posteriorly. From this point the circuit of extreme movement is completed by retrusion to the original point of departure at the most retruded hinge position of the jaw. The path is necessarily uneven because of the shifting contacts of the teeth. Proceeding form the most protruded contact position, where the lower incisors are anterior to the uppers, the path of the incisal point dips to the edge-to-edge contact of the incisors, rises to the position of complete occlusal interdigitation, then dips again as cusps are cleared to reach back to the terminal hinge position.

Movements in the transverse, or horizontal, plane can be similarly traced. Again beginning with the mandible in its most retruded (terminal hinge) position, the jaw is rotated to one side as far it will go with teeth just touching. In doing so it turns around a vertical axis somewhere behind the condyle on the side of the movement. If this is the left condyle it moves little, orbiting laterally in a small arc with a short radius of curvature. The condyle of the controlateral side, however, orbits in a long flat arc, since its radius of curvature is much longer. Thus the right condyle slides downward, forward, and inward to the anterior limit of the articular plane. This movement of the jaw carries the incisal point laterally and forward in a mild curve to the right. From this position the jaw is swung toward the midline in full protrusion. Thus the right condyle now slides downward, forward and inward to the interior limit of its articular plane. This movement carries the incisal point forward and medially in a mild curve to the same point of greatest protrusion visualized in the sagittal view (5).

The reverse action is now carried out by moving the jaw to the extreme of the left lateral excursion, the left lateral condyle thus moves up and back toward the most retruded position. Finally, the right condyle follows till mandible is returned to the original point of departure in the most retruded hinge position. The outline traced by the incisal point in this total excursion is

diamond-shaped, and it defines the marginal movements of the jaw in the horizontal (occlusal) plane. When these lateral movements are made with the jaw at increasing levels of opening, the diamonds become smaller and smaller until they disappear at the point of maximal opening identical with that visualized in sagittal view.

MUSCLES AND THE MOVEMENTS IN THE TEMPORO-MANDIBULAR JOINT

The mandibular muscles determine all the complicated postures and movements of the jaw. Their behavior can be greatly clarified by restating certain fundamentals crucial to purposive muscular activity. In the first place, there are three distinct roles that a muscle can play when activated: it can contract isotonically and shorten to act as a mover of a part; it can contract (tense) isotonically yet lengthen to act as a balancer for a moving part; and it can contract isometrically, hence neither shorten not lengthen, to act as a stabilizer of a movable part. In the second place, surprisingly large groups of distant muscles must act in the seemingly simplest functional movements.

When a jaw muscle contracts in the absence of a restraint, the mandible is pulled in the direction of the shortening muscle. The muscles have therefore been classified as protruders (lateral and medial pterygoids); retractors (posterior fibers of temporalis assisted by digastric and geniohyoid); elevators (anterior and middle fibres of temporalis, superficial and deep fibers of masseter and medial pterygoid); depressors (lateral pterygoids aided by digatric, geniohyoid and mylohyoid); lateral movers (medial and lateral pterygoids of each side).

All these muscles are active in all mandibular movements - some as movers, some as balancers, and some as stabilizers - shifting their role in accord with the progress of the movement. In close coordination with the above actions, muscles of the neck steady the cranium and hyoid bone to establish stable bases from which opening and closing muscles can pull (6). Since precise movements of the tongue are an integral part of masticatory activity, the hyoid bone is seen to move in rhythm with the jaw in chewing. It shifts continuously with firm stability to differing positions of mechanical advantage both for jaw opening and bolus manipulation.

Movements are described beginning from the centric occlusal posture with all teeth in even contact. In this position the elevators of the jaw are under active contraction, whereas in the rest position these muscles are safe to be in tonic contraction. There are two major movement sequences of the mandible in which some teeth come into contact: a cutting movement, such as that used by incisors and canines to bite off a piece of food, and a grinding movement, such as that used by molars and premolars to comminute a piece of food.

Both masticatory movement complexes - cutting and grinding - can be analyzed in three phases. The first, the opening or preparatory, phase is a free movement of the jaw. The second phase begins with the beginning closing action and ends at the approach of contact. The third phase is a truly articulatory movement. It occurs with the contact of teeth. The first phase requires little force. Considerable force may be applied during the second and third phases as these phases fuse to produce the masticatory stroke. Furthermore, in actual chewing true contact of teeth probably occurs rarely before many masticatory strokes have been made, depending on the

resistance of the food.

VASCULAR SUPPLY

The joint derives its arterial supply from the superficial temporal artery laterally and the maxillary artery medially. Veins drain the anterior aspect of the joint and associated tissues into the plexus surrounding lateral pterygoid, and posteriorly they drain into the vascular region that separates the two laminae of the bilaminar region of the disc (1).

In sagittal sections, the disc appears to possess a thin intermediate zone and thickened anterior and posterior bands, and its upper surface appears concavo-convex where it fits against the convex articular eminence and the concavity of the articular fossa. Posteriorly the disc is attached to a region of loose vascular and nervous tissue, which splits in two laminae, the bilaminar region. The upper lamina, composed of fibroelastic tissue, is attached to the squamo-tympanic fissure, and the lower lamina, composed of fibrous non-elastic tissue, is attached to the back of the condyle. The bilaminar region contains a venous plexus (1, 6, 7). Lymphatic drain deeply to the upper cervical lymph nodes is surrounding the internal jugular vein.

INNERVATIONS

The articular tissues and the dense part of the articular disc have no nerve supply. Branches of the auriculo-temporal and masseteric nerves and postganglionic sympathetic nerves supply the tissues associated with the capsular ligament and the looser posterior bilaminar extension of the disc. The temporo-mandibular joint capsule, lateral ligament and retroarticular tissue contain mechanoreceptors and nociceptors.

SPECTROPHOTOMETRIC DETERMINATION OF ENALAPRIL THROUGH TERNARY COMPLEX FORMATION **(Abstract):** Enalapril is an angiotensin-converting enzyme inhibitor widely used in the treatment of hypertension and heart failure. **Aim**: To design and validate a simple and sensitive spectrophotometric method. This method is based on a ternary complex formation between enalapril, copper (II), and bromothymol blue, in a slightly alkaline environment, complex that is extractable in chloroform, with an absorption maximum at 426 nm. **Materials and methods**: To a volume of 1 milliliter of standard enalapril drug solution in concentration range 200 ÷ 500 μg/ml, two milliliters of Cu (II) chloride solution 0.2 % followed by 2 ml bromothymol blue solution 0.01 % and 0.5 ml of pH 8 buffer solution (Britton-Robinson) were added. The complex was two times extracted with 2 × 1.5 ml chloroform. Ten minutes after extraction, absorbance was measured at 426 nm against blank. **Results**: Our spectrophotometric method was validated by determining linearity, limit of detection and quantification, system and method precision, and method accuracy. The method showed a good linearity in the range 200 ÷ 500 μg/ml (correlation coefficient r = 0.9993). Limit of detection (LD) was 9.907 μg/ml and limit of quantification (LQ) 33.024 μg/ml. Precision showed an RSD = 1.83%, and accuracy with mean recovery is 102.6 % in the range 98.8÷ 103.9. **Conclusions**: The ternary complex formed under the above-mentioned condition and measured spectrophotometrically can be regarded as an ion-association complex between the metal-drug cation and bromothymol blue anion. The experimental results demonstrated a good sensitivity. **Key words**: ENALAPRIL MALEATE, SPECTROPHOTOMETRIC METHOD, VALIDATION

Angiotensin converting enzyme inhibitors constitute one of the major classes of compounds used in the treatment of essential and renovascular hypertension and congestive heart failure. Enalapril is an ethyl ester of a long-acting ACE inhibitor, enalaprilat. It is basically a pro-drug, which after oral administration undergoes hydrolysis to yield enalaprilat and is used as its maleate salt in therapeutic indications. The oral absorption of enalapril is superior to that of enalaprilat. The official drug enalapril maleate is (1-[N-[(S)-1-carboxy-3-phenylpropyl]-L-alanyl]-L-proline 1'-ethyl ester, maleate (1:1)) (1, 2).

Many analytical methods have been reported in the literature for the analysis of enalapril maleate. The techniques include

spectrophotometry (2), spectrofluorimetry (3), ^{1}H nuclear magnetic resonance (NMR) spectroscopy (4). A number of high performance liquid chromatography (HPLC) (5, 6, 7) and gas chromatography (GC) methods (8) have been reported for the determination of enalapril.

This article presents a method developed and fully validated for the determination of enalapril.

MATERIAL AND METHODS

Instrumentation

A UV-VIS Hewlett-Packard 8453 spectrophotometer with quartz cells (l=1 cm) was used. A vibration shaker IKA-Werke type VX2 and ultrasonic bath were also used.

Materials and reagents

- Stock solution of enalapril maleate 1 mg/ml: 0.1 g enalapril (99.9% Zhejiang Huahai Pharmaceutical co., LTD, China) was dissolved in 1 ml methanol by ultrasonic bath. After dissolution, it was brought quantitatively to 100 ml with distilled water. Standard solution in concentration range 200-500 μg/ml was prepared from stock solution.
- Bromothymol blue (BTB) (Merck KGaA) 0.01% (w/v) aqueous solution.
- Copper (II) chloride ($CuCl_2.2H_2O$, Sigma Aldrich) 0.2% (w/v) aqueous solution.
- Buffer solution pH 8 (Britton Robinson). Equal volumes of acetic acid 0.04 M, phosphoric acid 0.04 M, and boric acid 0.04 M were mixed. To 100 ml of this mixture 60 ml of sodium hydroxide 0.2 M was added.

General procedure

To 1 ml of the standard drug solution in concentration range 200-500 μg/ml enalapril were added 2 ml of Cu (II) chloride solution 0.2 % followed by 2 ml of BTB solution 0.01 % and 0.5 ml buffer solution pH 8. The complex was two times extracted with 2 × 1.5 ml chloroform. The solution was shaken for 2 min each time. Absorbance of combined chloroform solutions was measured 10 minutes after extraction. Absorbance of the resulting solution was determined at 426 nm against blank prepared in the same manner.

RESULTS AND DISCUSSION

Ternary complexes of general formula ($L_NM_XS_Y$) have been widely used in spectrophotometric analysis. The particularity of the ternary complexes in this study is that their main ligand L is a drug (enalapril maleate), the second ligand S is bromothymol blue, and M is copper (II) (fig. 1).

The experimental conditions were established by varying and observing the different parameters that affect the absorbance of the stained product. The optimum experimental conditions were found to be: 2 ml Cu (II) chloride 0.2%, BTB solution 0.01 %, and 0.5 ml pH 8 buffer solution (Britton-Robinson). Two extraction of 2-min duration were found to be necessary for the quantitative determination of the complex. The best solvent for extraction was chloroform. At a concentration of less than 250μg/ml, the complex is stable 10 to 15 minutes after extraction. At concentration greater than 400μg/ml, the complex is stable for 45 minutes.

A series of absorption spectra have been recorded for each component and their mixtures under the above mentioned experimental conditions. The spectra revealed that chloroform solution of bromothymol blue absorbs at λ_{max}=267 nm, while neither copper (II) chloride nor the drug have maximum absorbance in the UV-VIS region. Enalapril-bromothymol blue and copper (II) chloride - bromothymol blue mixtures have the same

maximum absorption as bromothymol blue at λ_{max}=267 nm, while enalapril-copper (II) chloride mixture do not have maximum absorption in UV-VIS region.

The formed complex had maximum absorption at 426 nm (fig. 2).

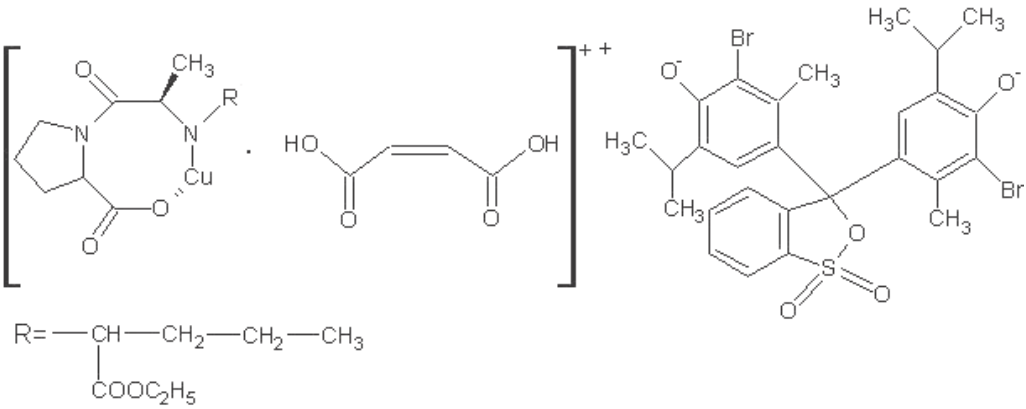

Fig. 1. Enalapril-Cu-bromothymol blue complex

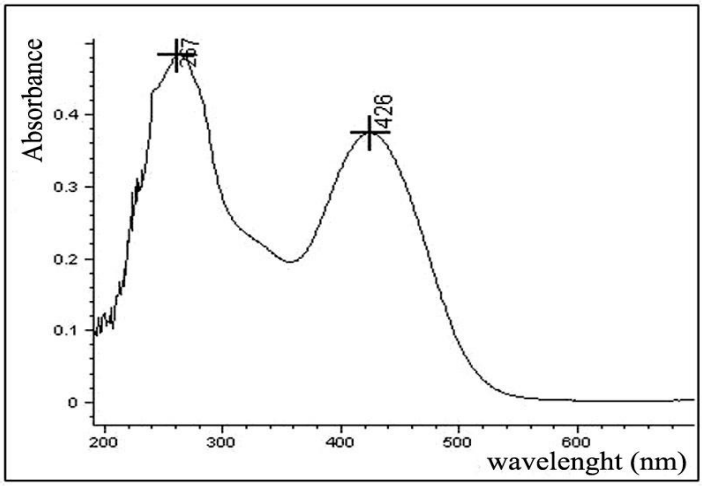

Fig. 2. Absorption spectrum of the ternary complex enalapril-Cu(II)-BTB

Calibration curves and validation

In order to validate the UV-VIS spectrophotometric method for enalapril assay, the following parameters have been studied: detection wavelength, linearity, detection and quantification limit, system and method precision, and the accuracy of the method (9).

For the stained compound, maximum absorption was at 426 nm.

A calibration curve for the formed complex was obtained by the standard procedure. A good linear relationship within the range 200-500 μg/ml was observed. For each concentration three determinations were made, and the mean absorbance was calculated and calibration curve drawn (fig. 3).

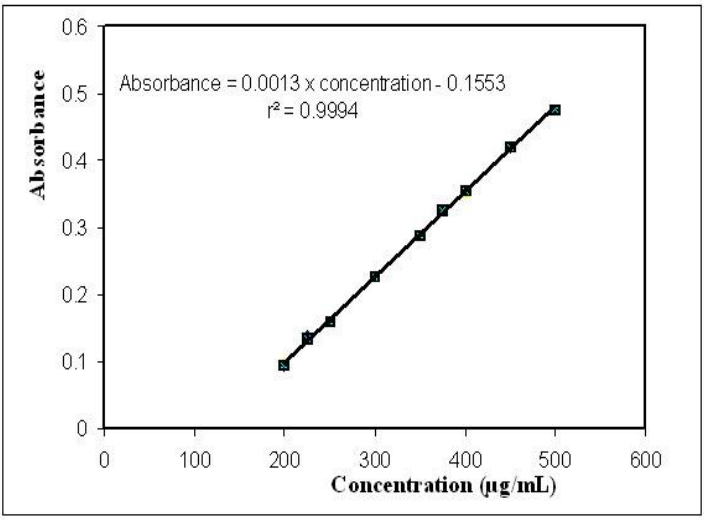

Fig. 3. Calibration curve

The analytical data, regression equation (Y = aX – b; a = slope and b = intercept), correlation coefficient (r), and regression coefficient (r^2) are summarized in tab. I.

To determine precision, system and method precision studies were performed.

In order to evaluate the precision of the system, ten determinations of the same sample (300 µg/ml) were done under the same experimental conditions, and then the relative standard deviation was calculated - RSD = 1.45, showing that the system is precise.

TABLE I

Linearity of the method and statistical data

Concentration (µg/ml)	Absorbance				Statistical data
	I	II	III	Average	
200	0.0902	0.0953	0.1008	0.0954	r = 0.9993 r^2 = 0.9994 SE = 0.0035 Intercept = - 0.1553 Slope = 0.0013 LQ = 33.024 µg/ml LD = 9.907 µg/ml
225	0.1394	0.1342	0.1319	0.1351	
250	0.1589	0.1596	0.1598	0.1594	
300	0.2297	0.2232	0.2295	0.2274	
350	0.2897	0.2895	0.2867	0.2886	
375	0.3245	0.3256	0.3244	0.3248	
400	0.3578	0.3542	0.3540	0.3553	
450	0.4187	0.4195	0.4202	0.4195	
500	0.4735	0.4785	0.4765	0.4762	

We have evaluated the precision of the method for a concentration range of ± 25% compared to the target value (300µg/ml). In order to validate the method (repeatability assessment) we analyzed two sets of samples, each on different day, with at least 9 determinations covering the specific concentration area (table II).

TABLE II

Precision of the method – first set and second set

Theoretical concentration (µg/ml)	Precision of the method First set			Precision of the method Second set		
	Absorbance (426 nm)	Calculated concentration (µg/ml)	Recovery (%)	Absorbance (426 nm)	Calculated concentration (µg/mL)	Recovery (%)
225	0.1377	225.4	100.2	0.1355	223.7	99.4
	0.1387	226.2	100.5	0.1398	227.0	100.9
	0.1329	221.7	98.5	0.1421	228.8	101.7
300	0.2457	308.5	102.8	0.2456	308.4	102.8
	0.2499	311.7	103.9	0.2502	311.9	104.0
	0.2468	309.3	103.1	0.2516	313.0	104.3
375	0.3459	385.5	102.8	0.3488	387.7	103.4
	0.3489	387.8	103.4	0.3512	389.6	103.9
	0.3497	388.4	103.6	0.3484	387.4	103.3
Statistical data		Mean	102.6		Mean	102.8
		SD	1.87		SD	1.64
		RSD	1.83		RSD	1.76

For the first set of determinations, we obtained RSD = 1.83, for the second set RSD = 1.76, values below 2%, but close to the precision of the system (RSD = 1.45). All these values confirm that the proposed method is precise.

In order to determine accuracy, we used the addition method at concentrations of: 225, 300 and 375µg/ml. Using the regression equation and the corresponding absorbance values, the concentration in µg/ml for each sample was calculated (table III).

TABLE III

The accuracy of the method

Theoretical concentration (µg/ml)	Absorbance (426 nm)	Calculated concentration (µg/ml)	Recovery (%)	Statistical data
225	0.1475	232.9	103.5	Mean = 103.2 Min = 101.4 Max = 104.9
	0.1514	235.9	104.9	
	0.1452	231.1	102.7

	0.3545	392.1	104.6	
	0.3547	392.3	104.6	

CONCLUSIONS

The ternary complex formed under the above mentioned conditions and measured spectrophotometrically can be regarded as an ion-association complex between the metal, drug cation and bromothymol-blue anion.

The proposed method is simple, fast and, highly sensitive); the detection limit was 9.907 µg/ml, and quantification limit 33.024 µg/ml.

The analysis method was validated at 426 nm optimum detection wavelength. We also studied the linearity of the method in the range of 200-500 µg/ml enalapril/ sample; the correlation coefficient was r^2 = 0.9994, precision of the system (RSD = 1.45), precision of the method (RSD = 1.83), and accuracy (mean recovery = 103.2 %).

The proposed method is simple, accurate, highly sensitive, with good precision and accuracy and is inexpensive.

PINI CEMBRAE CONI: HISTO-ANATOMICAL AND CHEMICAL STUDIES, ASSESSMENT OF ANTIOXIDANT ACTIVITY (Abstract): This study aimed to identify some histo-anatomical features, to evaluate the polyphenolic content and antioxidant activity of cembran pine female cones. **Material and methods**: The cross sections, obtained by usual techniques, were examined using a Novex microscope with a Canon A95 digital camera. For chemical and antioxidant assays dried cones were extracted with 80% aqueous methanol. The total phenolics, flavonoids and proanthocyanidins in cone extract were quantified by spectrophotometric methods. The antioxidant activity was investigated using different *in vitro* assays: ABTS radical cation scavenging assay, reducing power assay and ferrous ion chelating ability assay. **Results**: The histo-anatomical study of the seed-bearing scale revealed many secretory channels. The cone extract had low contents of total phenolics (48.03 ± 0.10 mg/g), flavonoids (8.11 ± 0.27 mg/g) and proanthocyanidins (1.63 ± 0.03 mg/g). The extract scavenged ABTS radical cation and reduced ferric ions to ferrous ions with EC_{50} values of 64.6 ± 0.8 and 118.60 ± 1.89 μg/ml, respectively being less active than the positive control, quercetin (EC_{50}=1.16 ± 0.05 and 2.58 ± 0.00 μg/ml, respectively). In ferrous ion chelating ability assay the extract showed a good activity (EC_{50}=1.2 ± 0.0 mg/ml) while quercetin was inactive. **Conclusions**: The ability of cone extract to chelate ferrous ions encourages further studies for identification of bioactive constituents and evaluation of their protective effects against ferrous ion-induced oxidative stress. **Key words**: *PINUS CEMBRA* L., POLYPHENOLS, ABTS, REDUCING POWER, FERROUS IONS CHELATION

Conurile de pin au fost considerate mult timp reziduuri forestiere şi, din acest motiv, compoziția chimică şi posibilele lor efecte biologice au fost puțin studiate.

În medicina tradițională japoneză, extractul apos din conurile speciei *Pinus parviflora* Sieb. et Zucc. era utilizat în tratamentul cancerului gastric (1).

Micales *et al.* au studiat compoziția chimică a conurilor de *Pinus contorta* Dougl., *Pinus jeffreyi* Grev. & Balf., *Pinus lambertiana* Dougl. şi *Pinus sylvestris* L.. În extractele eterice, au identificat, prin gaz-cromatografie, 16 acizi rezinici dintre care acizii dehidroabietic, isopimaric, abietic şi pimaric au predominat cantitativ.

Extractele au fost active faţă de unii fungi fitopatogeni (*Ceratocystis coerulescens*, *Trametes versicolor*) (1).

În conurile unor specii de *Pinus* au fost identificate antocianozide (3-glucozidele cianidolului, delfinidolului, petunidolului şi peonidolului) (2).

Studiul chimic al conurilor provenite de la specii de *Pinus* răspândite în Turcia (*Pinus halepensis* Mill., *Pinus pinea* L., *Pinus sylvestris* L., *Pinus nigra* L., *Pinus brutia* Ten.) a evidenţiat un conţinut polifenolic redus (0,06-1,70 mg/g) în extractele acetonice. În toate extractele a fost identificată catehina în concentraţii variabile de la 0,03 mg/g (în extractul din conuri de *Pinus sylvestris* L.) la 1,26 mg/g (în extractul din conuri de *Pinus halepensis* Mill.). Alţi compuşi identificaţi au fost: vanilina, acidul 3,4-dihidroxibenzoic, galocatehina, taxifolina şi izolaricirezinolul (3).

Până în prezent nu au fost efectuate studii privind histo-anatomia, compoziţia chimică şi posibilele efecte biologice ale conurilor femele de zâmbru (*Pinus cembra* L., *Pinaceae*). Obiectivele principale ale prezentului studiu au fost: stabilirea unor caractere histo-anatomice, determinarea conţinutului în polifenoli şi evaluarea potenţialului antioxidant al unui extract din conuri femele de zâmbru.

MATERIAL ŞI METODE

Materialul vegetal luat în studiu a fost constituit din conuri femele de zâmbru recoltate de la un exemplar matur în Parcul Naţional Călimani (aproximativ 1650 m altitudine) în luna iunie 2011. Materialul vegetal destinat studiilor histo-anatomice a fost fixat şi conservat în alcool etilic 70%. Pentru studiile chimice şi de evaluare a acţiunii antioxidante, conurile au fost uscate la temperatura camerei, ferite de lumină şi umiditate.

Secţiunile, realizate cu microtomul manual conform metodologiei uzuale (4), au fost colorate cu verde de iod şi roşu de ruteniu şi examinate la un microscop optic Novex prevăzut cu cameră foto digitală Canon A95.

20 g material vegetal, uscat şi pulverizat, au fost extrase cu 200 ml metanol 80% (v/v) sub agitare continuă, la temperatura camerei, timp de o oră. Extracţia a fost repetată de două ori; extractele au fost filtrate, reunite, concentrate sub presiune redusă la 40°C şi liofilizate obţinându-se 2,01 g extract (EC) (randament 10,05%).

Studiul chimic a presupus determinarea cantitativă a polifenolilor totali, flavonoidelor şi proantocianidolilor din extractul obţinut. *Conţinutul în polifenoli totali* a fost determinat prin metoda Folin-Ciocâlteu (5); rezultatul a fost exprimat în echivalenţi acid galic (mg acid galic/g extract). Pentru *determinarea cantitativă a flavonoidelor* s-a folosit o metodă spectrofotometrică bazată pe proprietatea acestora de a forma complecşi cu Al^{3+} (6); rezultatul a fost exprimat în echivalenţi (+)-catehină (mg (+)-catehină/g extract). *Conţinutul în proantocianidoli* a fost determinat prin metoda descrisă de Porter *et al.* (7); rezultatul a fost exprimat în echivalenţi cianidol (mg cianidol/g extract).

Acţiunea antioxidantă a extractului EC a fost evaluată prin determinarea capacităţii de scavenger faţă de radicalul cation ABTS, a capacităţii reducătoare şi a capacităţii de chelatare a ionilor feroşi. Ca martor pozitiv s-a utilizat cvercetolul dihidrat. CE_{50} (concentraţia căreia îi corespunde o activitate de 50%) a fost calculată prin interpolarea liniară a valorilor activităţilor imediat superioară şi imediat inferioară activităţii de 50%. În testul de evaluare a capacităţii reducătoare CE_{50} a reprezentat concentraţia corespunzătoare unei absor-

bante de 0,5.

Pentru determinarea *capacităţii de scavenger faţă de radicalul cation ABTS* (sarea de diamoniu a acidului 2,2'-azino-bis-3-etilbenzotiazolin-6-sulfonic) a fost utilizată metoda descrisă de Re *et al.* (8, 9). Activitatea de scavenger a fost exprimată procentual cu ajutorul formulei: % activitate de scavenger = 100 x ($A_{control}$ – $A_{probă}$)/ $A_{control}$, unde $A_{control}$ reprezintă absorbanţa controlului şi $A_{probă}$ reprezintă absorbanţa extractului/martorului pozitiv. Activitatea antioxidantă a fost exprimată şi prin valoarea TEAC (Trolox Equivalent Antioxidant Activity, activitate antioxidantă exprimată în echivalenţi Trolox) conform metodologiei descrise de Re *et al.* (8).

Capacitatea de a reduce ionii ferici la ioni feroşi a fost determinată prin metoda bazată pe formarea ferocianurii ferice (albastru de Prusia) (10).

Capacitatea de chelatare a ionilor feroşi (%), determinată prin metoda descrisă de Dinis *et al.*, a fost calculată folosind formula: 100 x ($A_{control}$ - $A_{probă}$)/$A_{control}$, unde $A_{control}$ reprezintă absorbanţa controlului şi $A_{probă}$ = absorbanţa extractului/martorului pozitiv (11).

Toate determinările chimice şi de evaluare a acţiunii antioxidante au fost efectuate în triplicat; rezultatele sunt prezentate ca media ± deviaţia standard.

REZULTATE ŞI DISCUŢII

Studiul histo-anatomic. Secţiunea transversală prin solzul carpelar are un contur aproximativ semieliptic. Ţesutul protector este reprezentat de o epidermă ale cărei celule de mărimi diferite sunt izodiametrice şi cu pereţii puternic îngroşaţi; peretele extern este acoperit de o cuticulă subţire, uşor ondulată. Din loc în loc, pe faţa externă a solzului carpelar se observă peri tectori. În poziţie hipodermică se află o zonă de celule parenchimatice foarte mici, de grosimi diferite. Sub aceasta se diferenţiază un parenchim format din două categorii de celule: unele mai mari, alungite perpendicular faţă de epidermă, cu peretele îngroşat şi lignificat şi altele mult mai mici, fără meaturi între ele, în partea centrală a solzului carpelar (fig. 1). În parenchimul fundamental se observă mai multe canale secretoare de diametre diferite; canalul colector este înconjurat de un strat de celule epiteliale mici (fig. 2). Ţesutul conducător nu formează fascicule libero-lemnoase tipice, colaterale, ci grupe de celule xilemice şi floemice cu orientare diferită, uneori cu floemul faţă în faţă.

Fig. 1. Secţiune transversală prin solzul carpelar imagine de ansamblu

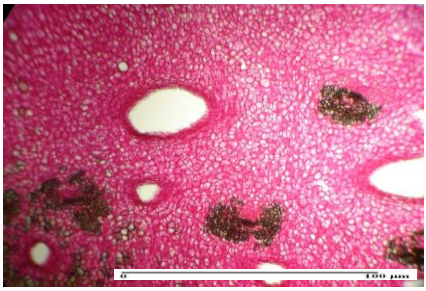

Fig. 2. Solzul carpelar – detaliu canale secretoare–

În secţiunea transversală de la nivelul ovulului tânăr se observă tegumentul care înconjoară nucela formată din celule poli-

gonale cu pereții foarte subțiri, fără meaturi între ele (fig. 3). Celulele sunt foarte tinere, cu caracter meristematic şi au nucleii mari. Pe seama unora dintre aceste celule, prin diviziuni succesive se va forma ulterior endospermul primar în care se vor edifica arhegoanele (fig. 4). Fiecare dintre acestea are partea bazală înconjurată de celule foarte mici; în arhegoane se vor forma gameții femeli.

Fig. 3. Secțiune transversală prin ovul – imagine de ansamblu

Fig. 4. Secțiune transversală prin ovul-începutul formării arhegoanelor

Studiul chimic. Studiul chimic cantitativ a evidențiat, pentru extractul EC, un conținut de 48,03 ± 0,10 mg polifenoli totali, 8,11 ± 0,27 mg flavonoide şi 1,63 ± 0,03 mg proantocianidoli/g extract. Rezultatele obținute sunt în concordanță cu date din literatura de specialitate conform cărora, în conurile speciilor de conifere, conținutul polifenolic este mai redus comparativ cu alte părți de plantă (scoarță, frunze) (3). Proantocianidolii, spre exemplu, se găsesc în cantități mari (până la 50%) în scoarțele de conifere (12).

Evaluarea acțiunii antioxidante. *Determinarea capacității de scavenger față de radicalul cation ABTS*. Rezultatele obținute sunt reprezentate grafic în figura 5. Extractul EC este mai puțin activ decât martorul pozitiv, cvercetolul. Astfel, extractul EC are o activitate de scavenger de 1,29 ± 0,09% la concentrația de 0,19 µg/ml; cvercetolul prezintă, la aceeaşi concentrație, o activitate de 9,64 ± 0,23%. La concentrația de 12,5 µg/ml cvercetolul inactivează complet radicalul în timp ce extractul EC are o activitate de numai 10,88 ± 0,39%. Această diferență de activitate este confirmată şi de valorile CE_{50} şi TEAC ale extractului EC şi cvercetolului (tab. I).

Determinarea capacității reducătoare. Valorile absorbanțelor obținute pentru extractul EC şi cvercetol în domeniul de concentrații 0,24 - 4 µg/ml sunt reprezentate grafic în fig. 6. Extractul EC prezintă o capacitate reducătoare mai mică decât martorul pozitiv, cvercetolul. Astfel, la o concentrație de 0,24 µg/ml, valoarea absorbanței amestecului de reacție, în cazul cvercetolului, este de 0,06 ± 0,00; la concentrația de 4 µg/ml valoarea absorbanței creşte la 0,71 ± 0,01. În acelaşi domeniu de concentrații, extractul EC este mai puțin activ. Astfel, la concentrația de 4 µg/ml, absorbanța amestecului de reacție este de numai 0,06 ± 0,00. În vederea calculării CE_{50} a extractului EC, au fost realizate diluții suplimentare (8,25 – 41,25 µg/ml). Capacitatea reducătoare scăzută a extractului EC este dovedită şi de valoarea CE_{50} a acestuia, mult mai mare decât cea a cvercetolului (118,60 ± 1,89 şi respectiv, 2,58 ± 0,00 µg/ml) (tab. I).

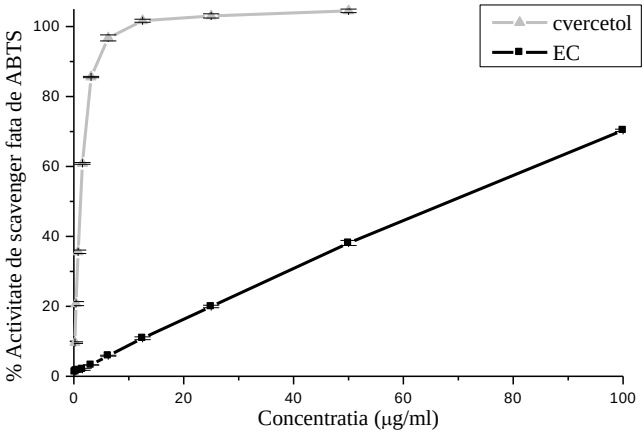

Fig. 5. Activitatea de scavenger faţă de radicalul cation ABTS (EC = extract din conuri de *Pinus cembra* L.)

Determinarea capacităţii reducătoare. Valorile absorbanţelor obţinute pentru extractul EC şi cvercetol în domeniul de concentraţii 0,24 - 4 μg/ml sunt reprezentate grafic în fig. 6. Extractul EC prezintă o capacitate reducătoare mai mică decât martorul pozitiv, cvercetolul. Astfel, la o concentraţie de 0,24 μg/ml, valoarea absorbanţei amestecului de reacţie, în cazul cvercetolului, este de 0,06 ± 0,00; la concentraţia de 4 μg/ml valoarea absorbanţei creşte la 0,71 ± 0,01. În acelaşi domeniu de concentraţii, extractul EC este mai puţin activ. Astfel, la concentraţia de 4 μg/ml, absorbanţa amestecului de reacţie este de numai 0,06 ± 0,00. În vederea calculării CE_{50} a extractului EC, au fost realizate diluţii suplimentare (8,25 – 41,25 μg/ml). Capacitatea reducătoare scăzută a extractului EC este dovedită şi de valoarea CE_{50} a acestuia, mult mai mare decât cea a cvercetolului (118,60 ± 1,89 şi respectiv, 2,58 ± 0,00 μg/ml) (tab. I).

Determinarea capacităţii de chelatare a ionilor feroşi. Rezultatele obţinute sunt reprezentate grafic în fig. 7. Deşi extractul EC este slab activ ca eliminator de radicali liberi şi agent reducător, acesta prezintă o bună activitate de chelatare a ionilor feroşi (CE_{50} =1,2 ± 0,0 mg/ml) (tab. I). La concentraţia de 0,5 mg/ml activitatea de chelatare a extractului EC este 6,27 ± 1,77%; la concentraţia de 4 mg/ml extractul EC chelatează ionii feroşi în proporţie de 98,07 ± 0,21%. În aceleaşi condiţii experimentale, cvercetolul este inactiv.

Ionii feroşi joacă un rol important în formarea de specii reactive ale oxigenului *in vivo*. Prin reducerea oxigenului molecular de către ionii feroşi ia naştere radicalul anion superoxid. În prezenţa ionilor feroşi peroxidul de hidrogen este convertit în radicali hidroxil (reacţia Fenton). Ionii feroşi se pot lega de oxigenul molecular cu formarea ionului perferil, deosebit de reactiv (13). În consecinţă, chelatarea ionilor feroşi reprezintă un mecanism important de reducere a stresului oxidativ. Având în vedere conţinutul polifenolic scăzut al extractului EC, este posibil ca, pe lângă polifenoli, şi alţi compuşi (oleorezine, saponine) să joace un rol important în activitatea de chelatare a ionilor feroşi.

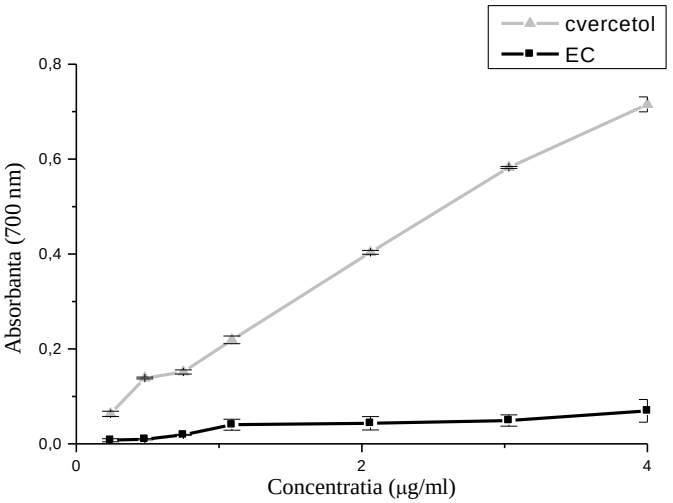

Fig. 6. Activitatea de reducere a ionilor ferici la ioni feroşi (EC = extract din conuri de *Pinus cembra* L.)

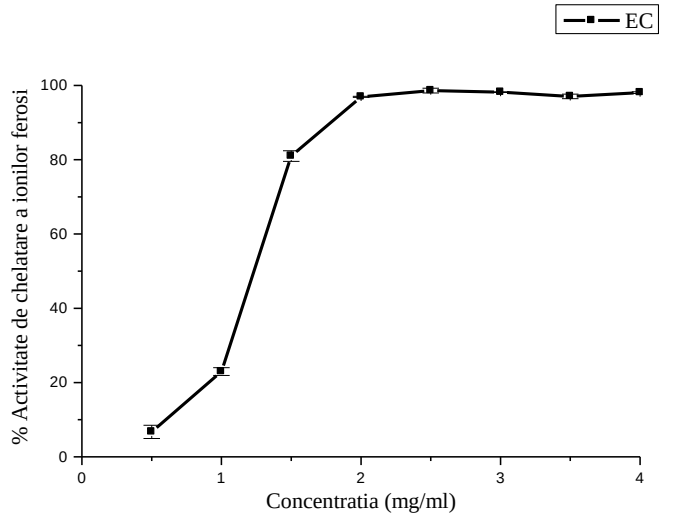

Fig. 7. Activitatea de chelatare a ionilor feroşi (EC = extract din conuri de *Pinus cembra* L.)

TABELUL I

Activitatea antioxidantă a extractului din conuri de *Pinus cembra* L.

Probă	Capacitatea de eliminare față de radicalul cation ABTS		Capacitatea reducătoare	Capacitatea de chelatare a ionilor feroşi
	CE_{50} [1]	TEAC [2]	CE_{50} [1]	CE_{50} [3]
Extract EC	64,6 ± 0,8	0,15 ± 0,00	118,60 ± 1,89	1,2 ± 0,0

[1]μg/ml; [2]μM Trolox echivalent la 1 μg/ml extract EC/cvercetol; [3]mg/ml

CONCLUZII

Studiul histo-anatomic la nivelul solzului carpelar a indicat prezența unui număr mare de canale secretoare, iar secțiunea transversală prin ovulul tânăr a permis observarea perioadei de început a dezvoltării arhegoanelor. Studiul chimic a evidențiat un conținut redus de polifenoli totali, flavonoide şi proantocianidoli în extractul din conuri. Studiul acțiunii antioxidante a extractului a indicat o activitate redusă ca eliminator de radicali liberi şi agent reducător. În schimb, extractul a fost activ în testul de chelatare a ionilor feroşi. Rezultatele obținute justifică continuarea cercetărilor pentru identificarea compuşilor activi şi evaluarea capacității protectoare față de stresul oxidativ indus de ionii feroşi.

Cristina Lungu Apetrei mulțumeşte Domnului Profesor Dr. Constantin Toma (Facultatea de Biologie, Universitatea "Al. I. Cuza"-Iaşi) şi personalului Administrației Parcului Național Călimani R. A. pentru sprijinul acordat în achiziționarea materialului vegetal.

FEATURES OF PUBERTAL MATURATION IN ADOLESCENTS FROM TIMIS COUNTY (Abstract): **Aim.** Puberty, by content and finality, mean all the events of somatic and mental maturation, with the transformation of the child into an adult. It is the period in which it is acquired the reproductive capacity. **Material and methods**. Pubertal maturation was studied on a sample of secondary school adolescents from Timis County, 800 students from schools and high schools in the urban area aged 11-14 years, with uniform distribution by sex and age. The pubertal evaluation was made with reference to Tanner stages. The result was an earlier and stronger pubertal maturation in girls compared with boys. **Results**. Pubertal maturation in adolescents from Timis County is higher compared to the national level (step 1999), and is less elevated compared with the local level of maturation (1998). **Conclusions**. The study contributes to maintain actual the health condition in adolescence.
Keywords: ADOLESCENCE, PUBERTY, AVERAGE PUBERTAL AGE

World Health Organization defines with the term adolescence the period of 10-19 years of the human life in which a person passes from the appearance of secondary sexual characteristics stage to the sexual maturity stage; psychological and identification characteristics ceases to be of the child and become of the adult, the transition is gradual, from the stage of total socio-economic dependence to relative independence stage.

Chronological ongoing of the maturation varies from one child to another, for genetic reasons and under the environment influence. Adolescence is characterized by the onset of some major events in terms of maturation: somatic growth leap and concomitant occurrence of secondary sexual characteristics, as well as the first menstruation and first ejaculation. Therefore, there is variability in the chronology of these events in the sense that an evaluation of growth based exclusively on chronological age may be inaccurate or wrong, particularly at the individual level (1,2).

Puberty, by content and finality, mean all the events of somatic and mental maturation, with the transformation of the child into an adult. Puberty is defined as the period in which it is acquired the reproductive capacity. Puberty is different than adolescence which means the entire period of growth from childhood to an adult and extends more than puberty, between 10-19 years (3-,4,5).

There is a wide range of normality in puberty. Normal puberty begins around 10

years, girls tending to start puberty a little earlier than boys. Physical manifestations of the puberty, especially occurrence of secondary sexual characteristics begin to appear at 11 years to 50% of girls and 11 ½ years to 50% of boys. Common manifestation at female puberty, breast enlargement, it is more visible than the first manifestations of male puberty, testicular growth. The increase in height during puberty occurs earlier in girls, while in boys installs later, with a two-year difference between the two genders in the sequence of events in time. Puberty lasts 3-4 years, with the passage from one stage to another, almost every year. Puberty varies widely and not only as matching in time but also in duration (6,7).

The study allows to maintain actual the health condition in adolescence at national level in Romania, started in 1950 with anthropometric measurements carried out every seven years to assess growth and development of children and adolescents between 0-18 years.

MATERIAL AND METHODS

The sample of secondary school students from Timis County totaled 800 students in schools and high schools from urban area. In the sample, the gender distribution was equal, 50% for boys and girls. Age of the students enrolled in the study was between 11-14 years, age and gender groups consisting of 100 adolescents each.

Pubertal evaluation was made with reference to Tanner stages (8, 9, 10).

Global score of pubertal development (Tanner J.M.) in boys:

- P1 - Prepuberty (absence of any development);

- P2 - Onset of puberty: rare pigmented hairs at the root of the penis or on the scrotum, which is slightly pigmented; testicular size between 2.5 - 3.2 cm (IVT slightly over 4 cm^3);

- P3 - Testicular development at 3.3 - 4 cm in the great axis, beginning of penis lengthening, development of pubic hair, possibly few axillary hairs;

- P4 - Progress of testicular development at 4.1 - 4.5 cm in the great axis, sharp increase in penis length and thickness, an adult type pubic pilosity without extending to the thighs or on the midline, body and axillary hair growth in progression; characteristic body odor, change of voice, acne, ejaculations;

- P5 - Adult testicular waist, over 4.5 cm in the great axis; adult type genitalia, pilosity that interest the midline and front of thighs roots, complete spermatogenesis.

Global score of pubertal development (Tanner J.M.) in girls:

- P1 - Prepuberty (absence of any development);

- P2 - Onset of puberty: subareolar breast, enlargement of the areolas, possibly some pigmented hairs on the outer labia or axillary;

- P3 - Development of palpable breast volume exceeding the areola contour, increased pubic and axillary pilosity; occurrence of characteristic body odor;

- P4 - The mammary gland continues to grow, taking pyriform aspect, adult type axillary and pubic pilosity, acne, imminent menarche;

- P5 - Adult-sized breasts, an adult-type pilosity that interest and the inner upper thigh root; menarche.

RESULTS AND DISCUSSIONS

1. The degree of pubertal maturation

Pubertal development of adolescents from the studied lot, by age and sex groups, have the following characteristics (table I).

TABLE I

Distribution of boys and girls of 11 - 14 years in the pubertal maturation stages

Age years	Sex	No.	Pubertal maturation stages									
			I		II		III		IV		V	
			No.	%	No.	%	No.	%	No.	%	No.	%

At 11 years predominates the adolescents from stage II, 66.0% (66) among boys and 38.0% (38) among girls. Boys are more numerous in stage I, 24.0% (24) than girls, 21.0% (21). In stage III, the representation is more important for girls, 25.0% (25) than boys, 10.0% (10). In stage IV and V are located only girls: 11.0% (11) and 5.0% (5). Representatives of the boys are missing in stages IV and V.

At 12 years, two thirds of the boys are in stages II and III, 37.0% (37) respectively 32.0% (32). Two thirds of the girls are in stages II, III and IV, with increasing percentages from 10.0% (10) to 21.0% (21) and 40.0% (40). The lowest percentages were recorded in stage I, 11.0% (11) for boys and 10.0% (10) for girls. Only girls have representatives in the stage V of puberty, 19.0% (19).

At 13 years we meet adolescents in all five stages of pubertal development. Three quarters among boys are classified in the stages III - 48.0% (48), IV - 26.0% (26) and V-3.0% (3). Over three quarters of the girls are in the last three stages, except that the percentages are increasing: in stage III - 17.0% (17), IV - 29.0% (29), V - 33.0% (33).

At age 14, boys are present in all five stages: lower rates of 5.0% (5) and 7.0% (7), in the first two; the highest in stage III - 49.0% (49) and IV - 32.0% (32); 7.0% (7) in the stage V. Girls are missing in the first stage and are poorly represented in the following two: 2.0% (2) in stage II and 5.0% (5) in stage III. One quarter of the girls are in stage IV, 25.0% (25), and two thirds in the stage V of puberty, 68.0% (68).

In the studied age range, between 11-12 years it is observed a progressive increase of subjects in higher stages of pubertal development, boys missing in stages IV and V. At 13-14 years, the distribution is in all 5 stages, with a significant decrease of the ones from the lower stages and increasing the proportion of pubescents.

Pubescent girls appear at 11 years, 5.0% (5), and the first pubescent boys, at 13, 3.0% (3).

2. The average pubertal age

Pubertal mean age (calculated as a weighted arithmetic average of ages of first menstruation in girls and first ejaculations in boys) is probably close to ideal maturation indicator: has a high level of validity, is easily appreciated and is comparable to the reference average. The only possible dilemma remains the possibility of questioning in some cultural contexts.

2. 1. The average pubertal age in girls

The first menstruation age to the 125 pubescent girls from the studied lot, ranged between 9-14 years with a peak frequency at 12 years (68). The pubertal mean age was 11 years and 9 months (11) (table II).

TABLE II

Distribution of girls aged 11-14 years according to the first menstruation

No. of cases	**Age of first menstruation (years)** / No. of cases						**Average pubertal age**
	9	**10**	**11**	**12**	**13**	**14**	
125	1	13	27	68	7	9	11years, 9 months
Romania, girls, urban area, 1999							12 years, 9 months
Banat Region, girls, urban area, 1998							11 years, 8 months

Compared with the average pubertal age to girls from Romania, urban area, 1999 (12), girls from Timis County had a mean pubertal less than 1 year.

Compared with the average pubertal age of girls from Banat Region, urban area, 1998 (13,14), the girls from Timis County had a mean pubertal age higher with one month.

2. 2. The average pubertal age in boys

First ejaculation age to the 10 pubescent boys in the investigated group, ranged between 13-14 years, the number of cases was 2.5 times higher in 14 years compared to 13 years. Pubertal mean age was 14 years (table III).

TABLE III

The distribution of boys aged 11-14 years according to the first ejaculation

No. of cases	**Age of first ejaculation /** No. of cases		**Average pubertal age**
	13	**14**	
10	3	7	14 years
Romania, boys, urban area, 1999			14 years, 4 months
Banat Region, boys, urban area, 1998			14 years, 2 months

Compared with the average pubertal age to boys from Romania, urban area, 1999, boys from Timis County have an average pubertal age of lower than 4 months. Compared with the average pubertal age in boys from Banat Region, urban area, 1998, the boys from Timis County have an average pubertal age lower than 2 months.

CONCLUSIONS

Pubertal maturation is earlier and more pronounced in girls than boys, and with age, the number of adolescents in Tanner stages is growing, and decreases in the lower stages. Boys prevail in Tanner stages I-III, with 2.2-15.5-17.8 % more than girls. Girls prevail in prepubertal stage IV with 6.7 % and pubescent stage V with 28.8 %. The first pubescent girls have 11 years and first pubescent boys have 13 years. At age 14, the ratio of pubescent girls / boys is 12.5 / 1.

The age of the first menstruation in girls is between 9-14 years, resulting a pubertal mean age of 11 years and 9 months. The age of the first ejaculation in boys is between 13-14 years and the pubertal mean age is 14 years. The average pubertal age is lower in girls compared with boys with 2 years and 3 months.

Pubertal maturation at the studied adolescents from Timis County, is higher than the national maturity level (stage 1999), and is less elevated than the regional level of maturity (1998).

AN INTERDISCIPLINARY APPROACH TO COMPLEX ORTHODONTIC-PERIODONTAL CLINICAL SITUATIONS IN ADULT PATIENTS (Abstract): Between orthodontics and periodontology there are many correlations, especially in the treatment of adults with already-damaged periodontal tissues and malocclusions. Aim of this paper was to emphasize that an interdisciplinary periodontal-orthodontic treatment could be beneficial even in a case that seemed hopelessly. A typical case of an adult patient with extensive bone loss due to periodontal disease, occlusal trauma caused by dental malpositions, spacing due to early loss of teeth in the lateral segments and pathologic tooth migration will be presented. The orthodontic treatment was initiated at 3 months after the stabilization of the periodontal therapy and was done with a fixed appliance. During the orthodontic stage periodontal maintenance visits continued at 2-month intervals. The therapy of “black triangles” occurred due to the loss of interdental gingiva was done by stripping followed by a space-closure procedure. A permanent retainer was applied. Benefits and problems of the comprehensive periodontal-orthodontic therapy and treatment protocols will be presented. In conclusion the interdisciplinary therapy of this patient, with a good compliance, was beneficial, improved esthetics, the periodontal status, the ability of the patient to clean the teeth and also led to best position of the abutments for optimal placement of prosthetic reconstructions. **Key words**: INTERDISCIPLINARY TREATMENT, ORTHODONTIC THERAPY, ADULT ORTHODONTICS, PERIODONTAL THERAPY, TREATMENT PROTOCOLS

Tratamentele ortodontice la pacienții adulți sunt parte a unei viziuni terapeutice globale, care presupune o abordare interdisciplinară ce implică o întregă echipă de specialişti în ortodonție, parodontologie, protetică, chirurgie orală şi maxilo-facială, echipă care să asigure astfel rezultate din ce în ce mai performante (1, 2).

Conform definiției lui Chester S. Handelman pacienții adulți care sunt susceptibili la boală parodontală şi au în antecedente pierderi avansate ale osului alveolar şi a unor unități dentare pot fi definiți ca şi pacienți ”compromişi parodontal”. Aceş-

tia constituie o categorie aparte deoarece: sunt mai predispuşi la pierderi osoase ulterioare, parodonţiul redus nu poate compensa pierderea în continuare de os alveolar existând riscul de a pierde dinţi, deseori prezintă şi o malocluzie dobândită iar parodonţiul redus obligă la un tratament ortodontic, o mecanică şi o contenţie specială (3).

Deseori adulţii prezintă anomalii dentomaxilare ”secundare” care nu au fost prezente odată cu erupţia dinţilor ci au apărut pe parcursul vieţii.

Tratamentul ortodontic la adulţii cu afecţiuni parodontale active este un dezastru deoarece deplasarea dentară poate accentua evoluţia bolii parodontale. De aceea se recomandă ca la aceşti pacienţi să se facă în primul rând terapia parodontală şi abia apoi, după ce se stabilizează statusul parodontal şi pacientul dovedeşte abilitatea de a menţine o igienă orală corectă se poate iniţia un tratament ortodontic.

Singura excepţie de la regula de a nu iniţia un tratament ortodontic în prezenţa inflamaţiei parodontale o constituie situaţiile clinice în care inflamaţia nu poate fi complet eliminată datorită malpoziţiilor dentare. În acest context situaţia poate fi îmbunătăţită prin terapie ortodontică (4).

Scopul acestei lucrări a fost de a evidenţia că o terapie interdisciplinară ortodontico-parodontală corect gândită şi aplicată poate fi benefică chiar şi în unele cazuri clinice ce par a fi iremediabil compromise.

PREZENTAREA CAZULUI

Pacientă prezentată este de sex feminin, cu vârsta de 32 de ani, compromisă parodontal, cu pierdere osoasă accentuată datorită bolii parodontale, traumă ocluzală cauzată de malpoziţiile dentare, spaţieri datorate pierderilor dentare precoce în zonele laterale cât şi datorită migrărilor dentare patologice (fig. 1).

Fig. 1. Status clinic intraoral înainte de iniţierea tratamentului ortodontic cu evidenţierea numeroaselor anomalii dento-maxilare, a edentaţiilor cât şi a retracţiilor gingivale datorate bolii parodontale.

Înainte de efectuarea terapiei parodontale pacienta prezenta adâncimi de sondaj mai mari de 5 mm, sângerarea gingiilor, retracţii gingivale cât şi mobilitate dentară. După etapa de terapie iniţială şi de conştientizare şi educare a pacientei în privinţa măsurilor de igienă orală s-a trecut la etapa de chirurgie parodontală pentru eliminarea pungilor parodontale şi reducerea inflamaţiei acute (fig. 2).

Fig. 2. Etapa de chirurgie parodontală

La 3 luni după stabilizarea tratamentului parodontal, în absența unei inflamații acute şi având în vedere existența atât a înghesuirilor dentare care îngreunează igienizarea optimă a interfeței dinte-gingie cât şi a spațierilor ce favorizează traumatizarea papilei interdentare s-a decis inițierea tratamentului ortodontic. Acesta s-a realizat cu aparat ortodontic fix, brackets metalici cu slot de 0,022. Pe parcursul tratamentului ortodontic fix care a durat 20 de luni, pacienta a fost odată la 2 luni la o evaluare parodontală de specialitate şi igienizare profesională. Pe tot parcursul tratamentului medicul ortodont a urmărit evoluția statusului parodontal pentru a semnala colegului parodontolog orice acutizare a afecțiunii parodontale. Pacienta a reuşit să mențină o igienă orală satisfăcătoare neexistând acutizări şi nefiind necesară întreruperea terapiei ortodontice.

Odată cu alinierea arcadelor dentare ambrazurile gingivale ajung la dimensiuni normale însă datorită papilelor interdentare reduse ca urmare a afecțiunii parodontale apare o entitate clinică inestetică cea a ”triunghiurilor negre” (black triangles, engl.). Terapia acestora se poate face fie prin augmentarea fiecărei papile interdentare fie printr-o ”mascare” a defectului. La acest caz datorită numeroaselor triunghiuri negre cât şi din dorința de a poziționa rădăcinile dentare cât mai în interiorul osului alveolar noi am ales a doua variantă prin care am redus proximal dinții implicați (stripping, engl.) şi apoi am închis spațiile. Prin aceasta ambrazurile gingivale s-au redus ca şi dimensiune, aria de contact a migrat spre gingival şi papila a fost ”comprimată” spre incizal ducând la camuflarea defectului (fig. 3).

Fig. 3. După realizarea stripping-ului am închis spațiile rezultate (săgeți) camuflând aspectul inestetic, caracteristic al ”triunghiurilor negre”.

La sfârşitul etapei de tratament ortodontic se observă o îmbunătățire considerabilă a esteticii dento-faciale, acesta fiind şi motivul principal pentru care pacienta s-a adresat medicilor dentişti (fig. 4).

Pentru menținerea alinierii arcadei dentare inferioare s-a aplicat o contenție fixă colată canin-canin. Pacienta a fost apoi îndrumată spre colegii parodontologi pentru inserarea implantelor dentare în zonele edentate şi refacerea ulterioară a continuității arcadelor dentare.

Fig. 4. Aspectul final după îndepărtarea aparatului ortodontic fix.

Pacienta a fost ulterior examinată periodic atât din punct de vedere parodontal cât şi din punct de vedere ortodontic constatându-se stabilitatea rezultatelor şi succesul terapiei interdisciplinare ortodontico-parodontale.

Din punct de vedere radiologic evoluția cazului a fost favorabilă cu menținerea nivelului osului alveolar şi obținerea unei topografii mai favorabile prin lărgirea septurilor interradiculare între dinții cu înghesuiri dento-alveolare ce au fost corectate (fig. 5).

Fig. 5. Evoluția radiologică a cazului, pe baza ortopantomografiilor, cu îmbunătățirea conturului osului alveolar

DISCUȚII

Existența unui protocol clar de colaborare în cadrul acestor echipe terapeutice interdisciplinare care să prevadă soluțiile la problemele ce pot apărea pe parcurs cât şi responsabilitățile fiecărui membru al echipei a dus la obținerea unor rezultate bune în situații care păreau compromise. Comunicarea permanentă între membrii echipei, facilitată şi de către tehnologia actuală digitală este esențială.

Din punct de vedere ortodontic terapia acestor pacienți adulți trebuie individualizată şi diferențiată de tratamentul ortodontic clasic. Datorită pierderii osoase generalizate implantarea dentară se reduce şi scade automat şi capacitatea de ancoraj. Astfel dinții au fost împărțiți în două categorii: cei care au o poziție relativ corectă (cei din zonele laterale) şi care au fost solidarizați pentru a constitui unități de ancoraj viabile şi dinții ce trebuiesc deplasați asupra cărora s-au aplicat forțe de intensitate redusă.

Având în vedere că prin deplasarea spre apical a centrului de rezistență al dinților (datorită reducerii înălțimii osului alveolar) tendința spre versie creşte am preferat să aplicăm brackets mai aplical (pentru a redu-

ce brațul forței și consecutiv și momentul) și am utilizat arcuri rectangulare de beta titanium ce permit un control mai eficient al deplasărilor dentare (5, 2). Arcurile de beta titanium au o combinație excelentă între rezistență și flexibilitate permițând o aplicare diferențiată a forțelor ortodontice cât și o individualizare a deplasărilor dentare.

CONCLUZII

Terapia interdisciplinară a acestei paciente, cu o bună complianță, a fost benefică îmbunătățind estetica, statusul parodontal, posibilitatea pacientei de a-și igieniza dinții și ducând la o amplasare optimă a unităților dentare în vederea unei reconstituiri protetice.

USE OF REAL TIME PCR FOR TESTING *STAPHYLOCOCCUS AUREUS* ISOLATES FROM THE IAŞI INFECTIOUS DISEASES HOSPITAL (Abstract): *S. aureus* is capable of producing a wide spectrum of diseases and can quickly develop resistance to antibiotics. These features require a careful monitoring of these organisms, by detection of resistance genes and virulence factors, such as Panton-Valentine leukocidin (PVL). **Aim:** To determine the presence of *mec*A and *pvl* genes in *S. aureus* isolates by a Real Time-PCR technique (RT-PCR) in order to shorten the detection time. **Materials and methods:** We tested 119 strains isolated from pus, using phenotypic methods for methicillin resistance characterization, according to CLSI 2008-2010 guidelines. Detection of *mec*A and *pvl* genes was done with hydrolysis probes. **Results:** The prevalence rate of methicilin resistant *S. aureus* (MRSA) was 40,33%, and *pvl* was detected in 52,08% of those strains. The results of the conventional methods for methicillin resistance detection were validated by those obtained by RT-PCR **Conclusions:** RT-PCR is useful in epidemiological surveillance of MRSA and PVL-producing strains and validation of test results for phenotypic resistance to oxacillin.
Key words: MRSA, *mec*A, PVL, PCR

Staphylococcus aureus este capabil să producă un spectru foarte larg de afecţiuni, de la infecţii minore, la infecţii cu potenţial letal. Apariţia tulpinilor rezistente la meticilină, care asociază frecvent rezistenţă multiplă la alte antibiotice, a dus la o creştere a mortalităţii şi a duratei de spitalizare. Cel mai frecvent, rezistenţa la meticilină este cauzată de achiziţia genei *mec*A, care codifică sinteza unei noi proteine de legare a penicilinei (PLP2a). Multă vreme, MRSA a fost asociat infecţiilor de spital, dar în ultimii ani a fost tot mai frecvent implicat în infecţii comunitare (*community aquired* MRSA: CA-MRSA), apărute la persoane tinere şi fără factori de risc cunoscuţi pentru infecţiile nosocomiale (1). Spectrul de boli cauzate de CA-MRSA variază de la

infecţii minore ale pielii şi ţesuturilor moi, la infecţii cu evoluţie severă rapidă şi adesea letale, precum: pneumonie necrozantă, osteomielită, abcese renale şi pulmonare, fasciită necrozantă, endocardită sau artrită septică. Virulenţa crescută a tulpinilor comunitare a fost asociată cu sinteza PVL, o exotoxină citolitică, prezentă în special la izolatele din leziuni dermonecrotice. Toxina este compusă din 2 proteine care acţionează sinergic, LukS PVL şi LukF-PVL, codificate de gene fagice şi are drept ţintă leucocitele polimorfonucleare, determinând formarea de pori la nivelul membranei citoplasmatice şi lizozomale, ceea ce duce la degranularea citoplasmei şi liză celulară (2). Prezenţa genelor care codifică PVL este considerată marker genetic stabil pentru infecţiile comunitare (1). Capacitatea tulpinilor CA-MRSA de a se răspândi rapid nu doar în comunitate, ci şi în mediul de spital, face necesară depistarea lor corectă, în timp scurt, în vederea instituirii măsurilor de prevenţie nespecifică. Metodele convenţionale de testare a sensibilităţii la antibiotice nu reuşesc sa evidenţieze întotdeauna meticilino-rezistenţa, în cazul tulpinilor heterorezistente şi, prin obligativitatea izolării bacteriei în cultură pură, presupun un timp mai indelungat pentru obţinerea profilului de sensibilitate la antibiotice. Tehnicile moleculare de detecţie a genei *mec*A sunt folosite, împreună cu metodele de evidenţiere a PLP2a, drept teste standard de confirmare pentru MRSA în cazul infecţiilor stafilococice severe (3). În acest studiu ne-am propus aplicarea tehnicii RT-PCR, utilizând infrastructura existentă în cadrul Disciplinei de Microbiologie a Facultăţii de Medicină a UMF „Gr. T. Popa” Iaşi, unde a fost pusă la punct relativ recent această metodă pentru detecţia genelor *mec*A şi *pvl* la izolate clinice de *S. aureus* din Spitalul Clinic de Boli Infecţioase „Sf. Parascheva” Iaşi.

MATERIAL ŞI METODĂ

Au fost testate 119 tulpini de *S.aureus* izolate din exsudate purulente, de la pacienţi internaţi în Spitalul Clinic de Boli Infecţioase „Sf. Parascheva” Iaşi, în perioada ianuarie 2008-decembrie 2010. Depistarea MRSA s-a făcut prin metoda difuzimetrică cu disc de 30 µg cefoxitin şi determinarea CMI a oxacilinei cu benzi E-test (bioMerieux, Franţa). Rezultatele testării fenotipice au fost verificate prin *singleplex* RT-PCR pentru amplificarea genei *mec*A. Depistarea tulpinilor producătoare de PVL s-a făcut prin *singleplex* RT-PCR pentru detecţia genelor *pvl*. În paralel, au fost testate tulpinile de referinţă *S. aureus* ATCC 25923 şi 49775 (*pvl* prezent, *mec*A absent) şi *S. aureus* ATCC 33592 (*mec*A prezent, *pvl* absent), drept martori pozitivi şi negativi. Pentru extracţia ADN stafilococic am folosit kitul *GenEluteTM Bacterial Genomic* DNA, lizostafin şi lizozim (Sigma Aldrich, Germania). Amplificarea şi detecţia cu sonde de hidroliză TaqMan a genelor *mec*A şi *pvl* s-a făcut utilizând instrumentul Stratagene Mx3005P, *Brilliant II QPCR Master Mix* (Agilent Technologies, SUA), primeri şi sonde de hidroliză mecA şi pvl (Biosearch Technologies, Inc., SUA) (tab. I).

Protocolul de lucru este descris în tab. II - V. Am realizat fiecare reacţie în triplicat, pentru verificarea reproductibilităţii rezultatelor.

REZULTATE

Prezenţa genelor amplificate a fost indicată prin creşterea fluorescenţei fluorocromului cu care a fost marcată sonda de detectare. Canalele de fluorescenţă utilizate au fost FAM şi Cy5, pentru detectarea sondelor marcate cu FAM şi respectiv Quasar 670, Gena *mec*A a fost detectată la 48 de izolate, reprezentând 40,33% din totalul tulpinilor testate. Numărul tulpinilor *pvl* pozitive a fost de 37, respectiv 31,09% din total şi 52,08% din tulpinile MRSA (tab. VI). Rezultatele testărilor fenotipice au fost interpretate conform standardelor CLSI (*Clinical Laboratory Standards Institute*) 2008–2010 şi s-au corelat cu detectarea meticilino-rezistenţei prin biologie moleculară. Curbele de amplificare a genelor *mec*A şi *pvl* sunt prezentate în fig. 1 şi 2.

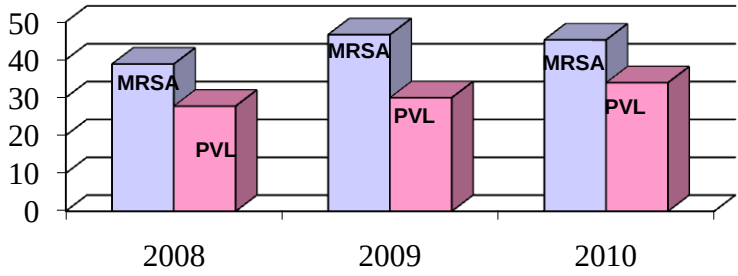

Fig. 3. Prevalenţa tulpinilor MRSA şi a tulpinilor PVL+

DISCUŢII

Detecţia genei *mec*A prin RT-PCR s-a corelat cu determinarea meticilino-rezistenţei prin metode fenotipice. Rezultatele noastre sunt similare cu cele publicate de Anand *et al*. (2009) şi Pottumarthya *et al*. (2005), care raportează o sensibilitate a testării cu discul de 30 µg cefoxitin de 100% şi respectiv 99% (5,6). Rata infecţiilor cu tulpini MRSA şi PVL pozitive a variat nesemnificativ pe parcursul celor 3 ani ($p > 0,05$) (fig. 3). Prevalenţa MRSA remarcată în cursul studiului (40,33%) este în acord cu date publicate anterior de Dorneanu *et al* (8) în 2006 (47%) şi cu raportările *European Antimicrobial Resistance Surveillance Network* (EARS-Net), care plasează România pe unul dintre primele locuri privind incidenţa MRSA izolat din infecţii invazive (35.6%) (9). Menţinerea prevalenţei MRSA la un nivel redus presupune un program riguros de prevenţie, prin *screening*-ul la internare al pacienţilor cu risc înalt de a fi colonizaţi. Folosirea RT-PCR oferă în perspectivă posibilitatea depistării MRSA direct în probă şi instituirea rapidă a măsurilor de prevenţie a răspândirii acestor tulpini în spital, ceea ce reprezintă un avantaj evident al folosirii tehnicilor de biologie moleculară (3, 4). Conform datelor din literatură, MRSA poartă mai frecvent, comparativ cu tulpinile sensibile la meticilină, gene care codifică sinteza unor toxine (85,5% versus 53,8%)(10), iar unele tulpini comunitare sunt mai virulente decât cele de spital (2). Expresia PVL este puternic asociată cu CA-MRSA, 96% dintre izolatele PVL pozitive fiind CA-MRSA (11). Studiul nostru a evidenţiat o rată crescută a infecţiilor cu tulpini MRSA, PVL pozitive (21%). Procentul de tulpini PVL pozitive raportat în literatură variază considerabil de la un autor la altul (între 2-66%), probabil datorită circulaţiei diferite a acestor tulpini în anumite regiuni. Într-un studiu realizat de Fang *et al.* (2008) dintre 104 tulpini CA-MRSA izolate în Stockholm în perioada 2000-2005, 56 % au prezentat genele *pvl* (12). Berglund *et al* (2011) a detectat genele *pvl* la 66% dintre tulpinile CA-MRSA (13), în timp ce Holmes *et al* (2005) a remarcat un procent redus de izolate de *S. aureus* purtătoare ale acestor gene (1,6%) (14). S-a observat asocierea tulpinilor producătoare de PVL cu o severitate crescută a leziunilor localizate şi un răspuns inflamator sistemic accentuat (15). Unii autori remarcă o infiltrare a tulpinilor comunitare în mediul de spital şi prezic înlocuirea tulpinilor clasice de spital de către tulpinile CA-MRSA, dotate cu proprietăţi deosebite de colonizare (16).

CONCLUZII

Creşterea fenomenului de rezistenţă la antibiotice impune o strictă monitorizare a tulpinilor de *S. aureus* circulante, cu identificarea izolatelor purtătoare ale genelor de rezistenţă. Dezvoltarea tehnicilor moleculare, mai rapide, specifice şi sensibile comparativ cu cele clasice reprezintă o perspectivă atrăgătoare. Detectarea genei *mec*A în cadrul laboratorului nostru a permis confirmarea rezultatelor testării fenotipice pentru rezistenţa la oxacilină, scurtând timpul de detecţie. În pofida unor costuri mai mari, tehnica face posibilă instituirea precoce a măsurilor preventive, cu economisirea fondurilor aferente diagnosticării şi tratării cazuilor secundare răspândiri acestor utilpini în comunitate.

În cadrul acestui studiu a fost evaluată pentru prima dată prevalenţa tulpinilor de *S. aureus* producătoare de PVL pentru izolate clinice din exsudate purulente din Spitalul Clinic de Boli Infecţioase „Sf. Parascheva” Iaşi. Prevalenţa crescută a tulpinilor de *S. aureus* producătoare de PVL (31,09%) şi

implicaţia lor în patologia infecţioasă face necesară detectarea acestora, datele putând fi utilizate, în asociere cu tehnicile de tipare, pentru identificarea tulpinilor CA-MRSA şi supravegherea epidemiologică a circulaţiei lor.

MULŢUMIRI

Cercetările descrise în acest studiu au fost posibile cu finanţare CNCSIS – UEFISCSU, prin proiectul PNII – IDEI cod ID_1586/2008.

DERMOID CYST OF THE PAROTID GLAND (Abstract): Dermoid cyst of the parotid gland is a rare clinical entity. Definitive clinical diagnosis is often difficult to determine preoperatively because of the lack of pathognomonic features. The most frequent location of a parotid dermoid cyst is a triangular area lying above the pinna. Imaging studies do not definitely diagnose a parotid dermoid cyst. Although parotid dermoid cyst is (generally) well-encapsulated, complete removal of the cyst wall is not sufficient to cure it, so it is mandatory to perform careful excision of the cyst by parotidectomy, in terms of preserving facial nerve integrity. Histopathology of the parotid gland tumor removed by parotidectomy makes a diagnosis of certainty, by revealing a cyst wall with keratinization of the squamous epithelium and the presence of skin annexes (hair follicles, sweat glands, sebaceous glands). We present a rare case of parotid dermoid cyst in a 21-year-old male patient with symptoms and imaging rather suggestive of arch I branchial cyst and a brief review of data in the medical literature of the last 20 years. **Key words:** DERMOID CYST, PAROTID GLAND, TRUE HAMARTOMAS

Chistul dermoid este o formă de teratom cu diferenţiere ectodermică, fiind rezultatul incluziei unor celule epiteliale de-a lungul liniilor de sutură embrionare (1,2). La nivelul segmentelor capului şi gâtului, această entitate clinică este mai puţin întâlnită, reprezentând aproximativ 7% dintre toate chisturile dermoide ale corpului (3, 4). În aria cap-gât, chisturile dermoide sunt decelate predominant la nivelul regiunilor: orbitară, orală şi nazală (peste 80%), cu următoarele frecvenţe raportate: 49,5% (pentru orbite), 12,6% (nas), 23,3% (regiunile submentală şi submandibulară) şi respectiv 14,6% - alte regiuni (occipitală, frontală, labială, cervicală, văl palatin) (4). Pentru teritoriul oro-maxilo-facial, cele mai multe cazuri de chisturi dermoide descrise în literatura medicală internaţională sunt cele localizate în planşeul bucal, situarea parotidiană a unui chist dermoid fiind considerată foarte rară, atât la adulţi cât şi la copii (1,2,5,6).

Dintre toate leziunile glandei parotide,

cele chistice reprezintă 2-5% şi pot fi: chisturi parotidiene congenitale sau chisturi parotidiene dobândite (obstrucţie, tumori, calculi, traumatisme, paraziţi) (4). Leziunile chistice congenitale ale glandelor parotide sunt clasificate în: chisturi dermoide, chisturi de arc branhial, chisturi de diverticul branhial, chisturi ductale. Un chist parotidian se poate dezvolta în orice porţiune a glandei, diagnosticul clinic preoperator fiind dificil de stabilit, în special în cazurile localizărilor profunde faţă de nervul facial. Explorările imagistice precum: tomografia computerizată, imagistica prin rezonanţă magnetică sau ultrasonografia nu pot furniza un diagnostic decisiv preoperator (6). În multe situaţii, diagnosticul definitiv se stabileşte după excizia leziunii.

Prezentăm un caz clinic de chist dermoid parotidian, la care suspiciunea diagnostică iniţială (preoperator şi chiar intraoperator) a fost de chist de arc I branhial cu localizare parotidiană, motivată de: vârsta pacientului, localizarea formaţiunii tumorale, evoluţia clinică cu numeroase episoade inflamatorii locale, aspectul imagistic, consistenţa lichidiană precum şi de recunoaşterea statistică a frecvenţei mai crescute a chisturilor branhiale între tumorile chistice parotidiene.

PREZENTAREA CAZULUI

În Clinica de Chirurgie Orală şi Maxilo-Facială Iaşi, s-a prezentat în mai 2010 un pacient de sex masculin, în vârstă de 21 ani, cu domiciliul în judeţul Bacău, motivul internării fiind deformarea regiunii parotidiene stângi (anterior şi inferior de lobulul urechii) printr-o formaţiune tumorală rotundă, de aproximativ 4 cm în diametru, renitent-elastică, nedureroasă, mobilă odată cu glanda parotidă, evoluţia clinică declarată fiind de un an (fig. 1 şi 2). S-a remarcat totodată că tegumentul acoperitor corespondent formaţiunii prezenta uşoară congestie şi era relativ aderent la tumora subiacentă.

Fig. 1. Tumoră parotida stângă (aspect faţă preoperator)

Fig. 2. Tumoră parotida stângă (aspect semiprofil stâng preoperator)

Antecedentele personale şi heredo-colaterale ale pacientului erau nesemnificative. Examenul clinic obiectiv pe aparate şi sisteme nu a decelat alte elemente patologice.

S-a efectuat o *tomografie computerizată*

pentru segmentul „cap”, evidențiindu-se prin explorare nativă la nivelul porțiunii posterioare a glandei parotide stângi *o imagine cu densitate lichidiană de 42 mm/48 mm, bine delimitată*, care nu infiltrează țesuturile adiacente, se insinuează posterior de ramul ascendent al mandibulei şi are efect de masă asupra venei retromandibulare pe care o deplasează medial (fig. 3).

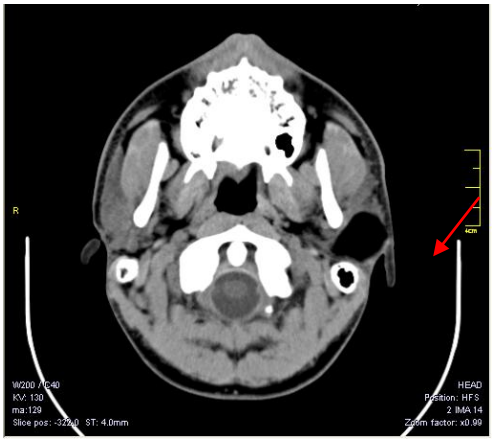

Fig. 3. Aspect computertomografic al formațiunii tumorale parotidiene stângi

Intraoperator, după expunerea glandei parotide stângi, s-a constatat la nivelul lobului superficial o *formațiune chistică*, cu un perete inegal, relativ aderentă la țesutul glandular adiacent. S-a efectuat *extirparea tumorii chistice parotidiene* respective prin *parotidectomie superficială stângă cu conservarea nervului facial* (fig. 4). În timpul manevrelor de disecție a lobului superficial parotidian, s-a întrerupt accidental continuitatea peretelui formațiunii chistice, eliberându-se un *conținut lichidian cu cristale de colesterină*. Intervenția chirurgicală a mai notat o particularitate, şi anume: *extinderea peretelui chistic până la nivelul conductului auditiv extern stâng*, aderența moderată stabilită între cele două elemente îngreunând disecția propriu-zisă. Toate aceste aspecte intraoperatorii au motivat orientarea de moment către diagnosticul de *chist congenital de arc I branhial*. Datorită împrăştierii conținutului chistului către țesuturile şi structurile anatomice vecine, după extirparea formațiunii menționate odată cu țesutul parotidian „gazdă” s-a procedat la toaletarea plăgii operatorii cu soluție de betadină 1%, pentru a evita o eventuală reacție de corp străin sau o potențială complicație infecțioasă.

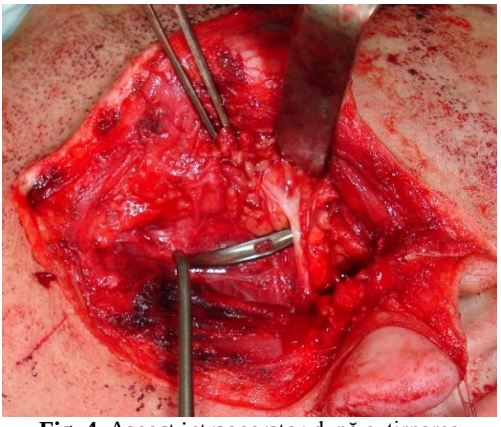

Fig. 4. Aspect intraoperator după extirparea tumorii prin parotidectomie superficială stângă cu conservarea nervului facial

Examenul histopatologic definitiv al piesei operatorii (A.P. nr. 78286/07.05.2010) a descris: formațiune *chistică*, cu perete sclerohialin gros, ce îngloba în unele zone numeroase *fire de păr*; s-au mai remarcat numeroase *chisturi lipidice* şi aspecte de *lipogranulomatoză*, cu evidențierea fragmentelor parotidiene pe versantul extern al chistului. Concluzia examenului morfopatologic al specimenului operator fixat a fost: *chist dermoid cu remaniere şi organizare conjunctivă* (fig. 5,6,7 şi 8).

Evoluția postoperatorie a fost obişnuită, favorabilă, cu cicatrizare corectă a plăgii şi fără semne ale paraliziei de nerv facial stâng (fig. 9 şi 10).

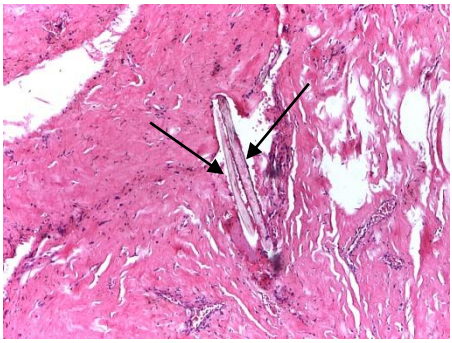

Fig. 5. Aspect microscopic al piesei operatorii (colorația hematoxilină-eozină, mărire obiectiv x4) cu evidențierea firelor de păr secționate longitudinal, la nivelul peretelui chistic sclerohialin: chist dermoid

DISCUȚII

Chisturile dermoide ale capului şi gâtului sunt relativ rare, constituind doar 7% din totalul chisturilor dermoide ale corpului. Frecvența chisturilor dermoide este şi mai mică pentru regiunea parotidiană, aceste cazuri fiind sporadic decelate şi raportate (5). În Clinica de Chirurgie Orală şi Maxilo-Facială Iaşi, în perioada 2006-2010, au fost diagnosticate şi tratate 4 cazuri de chisturi dermoide cu localizare parotidiană, unul dintre acestea fiind cel prezentat mai sus.

Termenul de „chist dermoid" este utilizat actualmente pentru a descrie formațiuni care pot fi: chist epidermoid, chist dermoid sau chist teratoid (7). Din punct de vedere histologic, chisturile dermoide adevărate sunt căptuşite de epiderm şi prezintă anexe ale pielii precum: glande sudoripare, glande de sebacee, peri şi foliculi piloşi. Dacă aceste anexe lipsesc din alcătuirea peretelui chistului, termenul folosit este de „chist epidermoid". Dacă peretele chistic prezintă structuri derivate din toate cele trei straturi germinale (ectoderm, mezoderm şi endoderm), entitatea respectivă se defineşte ca fiind un „teratom" sau „chist teratoid" (8). Conținutul chistului dermoid poate fi reprezentat de: cheratină, cazeum, sebum, puroi, peri, unghii, celule adipoase, cristale de colesterină, cartilaj. Prin prisma acestor mențiuni histopatologice, cazul raportat de noi s-a dovedit a fi un chist dermoid adevărat, cu localizare în glanda parotidă, cu toate că lichidul intrachistic observat intraoperator avea un aspect mai sugestiv pentru chistul branhial.

Chisturile dermoide sunt leziuni congenitale rare, derivate din celule pluripotente. Cea mai credibilă teorie embriologică privind dezvoltarea acestor formațiuni este cea care susține incluzia eronată a unor celule pluripotente, în timpul primelor săptămâni de viață intrauterină, care conduce la dezvoltarea ulterioară a structurilor din unul sau din toate cele trei straturi germinale: ectoderm, mezoderm, endoderm (9). Diferențierea acestor straturi germinale produce: anexe ale pielii (păr, glande sebacee şi sudoripare), muşchi, oase, cartilaj, dinți, membrane mucoase. Cauzele acestor modificări pot fi: traumatisme, infecții sau creşteri autonome spontane. Astfel se explică cele trei varietăți de chisturi descrise anterior, clasificate după caracteristicile histologice: chistul epidermoid este căptuşit de un epiteliu scuamos stratificat şi este alcătuit dintr-un singur strat germinal (ectoderm); chistul dermoid este căptuşit de un epiteliu stratificat, prezentând şi anexe ale pielii (origine ectodermică şi mezodermică); chistul teratoid este alcătuit din structuri cu triplă origine: ectodermică, mezodermică şi endodermică.

Chisturile dermoide sunt frecvent situate în regiunile unde se produc fuziuni între mugurii embrionari. Majoritatea cazurilor raportate sunt pe linia mediană a corpului. Pentru teritoriul oro-maxilo-facial sunt descrise următoarele localizări: linia mediană a planşeului bucal (sublingual sau submental), palatul (dur sau moale), limba, regiunile geniene, glandele parotide, maxilarele şi mandibula (10,11). Chisturile dermoide parotidiene prezentate în literatura medicală de specialitate interesează toate vârstele, inclusiv copiii (1,2,3,4,5). Cazul nostru aparține unui adult tânăr, încadrându-se de altfel în cea mai frecventă categorie de vârstă afectată de această patologie.

Diagnosticul clinic definitiv de chist dermoid parotidian este dificil de stabilit. Examenul fizic nu poate decela elemente caracteristice acestei leziuni parotidiene. Diagnosticul diferențial al unei tumori chistice parotidiene aduce în discuție (în

afara chistului dermoid): chistul branhial, chistul unui diverticul branhial, chistul ductal congenital sau un chist dobândit al glandei parotide. Consistența predominant lichidiană a conținutului chistului parotidian descris de noi a motivat orientarea intraoperatorie mai curând către un chist branhial şi nu către un chist dermoid, acesta din urmă având adesea o consistență mai păstoasă (asemănătoare „grişului cu lapte") şi o culoare alb-gălbuie. Mai mult, în cazul relatat, localizarea profundă, intraparenchimatoasă, sub nivelul lobului urechii ar fi pledat de asemenea pentru un chist cu originea în arcul I branhial.

Sialografia poate releva un sistem ductal parotidian normal sau o uşoară compresiune la nivelul său. Explorările imagistice mai performante precum ecografia, examenul prin tomografie computerizată sau imagistica prin rezonanță magnetică nucleară sunt utile pentru stabilirea densității şi extinderilor tumorale dar nu pot concluziona definitiv existența unui chist dermoid parotidian. În cazul nostru, explorarea prin tomografie computerizată a fost orientativă, evidențiind o densitate lichidiană pentru tumora parotidiană. De menționat că, au fost raportate în literatură confuzii preoperatorii ale unor chisturi dermoide parotidiene cu lipoamele parotidiene (3,4, 6). Studiul imagistic prin rezonanță magnetică nucleară are însă o acuratețe mai mare în evaluarea diseminărilor picăturilor grăsoase într-un chist dermoid, acestea fiind caracteristice pentru diagnosticul unui chist dermoid cervical.

Evaluarea completă a unui chist dermoid parotidian ar trebui să includă şi examenul citologic prin puncția-aspirație cu ac fin, după examenul fizic minuțios şi investigația imagistică. Această explorare poate pune în evidență resturi de epiteliu scuamos cu sau fără nuclei precum şi resturi de keratină, trăsături considerate sugestive pentru un chist dermoid. Aspirația cu ac fin este o metodă care poate îmbunătăți în mod real diagnosticul preoperator de chist dermoid parotidian (5,12).

Examenul histopatologic al unui chist dermoid parotidian relevă un perete chistic cu cheratinizarea epiteliului scuamos precum şi prezența anexelor pielii (foliculi piloşi, glande sudoripare, glande sebacee) (4, 13). Diagnosticul definitiv în cazul descris mai sus s-a stabilit în urma detaliilor caracteristice oferite de studiul de microscopie optică al piesei operatorii.

Un chist dermoid al glandei parotide este, în general, relativ bine încapsulat, astfel încât extirparea sa este oarecum mai facilă față de chisturile dermoide cu localizare în regiunile orbitară sau nazală. Dar simpla excizie a chistului poate conduce la persistența unor resturi microscopice de țesut, astfel încât leziunea va recidiva mai târziu. Pentru vindecarea completă a unui chist dermoid parotidian este obligatorie extirparea sa împreună cu țesutul parotidian în care s-a dezvoltat (parotidectomie). În cazul relatat în prezentul material, decizia extirpării tumorii parotidiene prin parotidectomie superficială s-a luat preoperator şi din considerentul evoluției profunde, intraparenchimatoase a leziunii. Evoluția postoperatorie a fost favorabilă, fără a se consemna recidivă după un an de la intervenția chirurgicală. Un chist dermoid al glandei parotide este, în general, relativ bine încapsulat, astfel încât extirparea sa este oarecum mai facilă față de chisturile dermoide cu localizare în regiunile orbitară sau nazală. Dar simpla excizie a chistului poate conduce la persistența unor resturi microscopice de țesut, astfel încât leziunea va recidiva mai târziu. Pentru vindecarea com-

pletă a unui chist dermoid parotidian este obligatorie extirparea sa împreună cu țesutul parotidian în care s-a dezvoltat (parotidectomie). În cazul relatat în prezentul material, decizia extirpării tumorii parotidiene prin parotidectomie superficială s-a luat preoperator şi din considerentul evoluției profunde, intraparenchimatoase a leziunii. Evoluția postoperatorie a fost favorabilă, fără a se consemna recidivă după un an de la intervenția chirurgicală.

CONCLUZII

Deşi chistul dermoid al glandei parotide este o entitate clinică rar întâlnită şi nu prezintă aspecte clinice sau imagistice patognomonice trebuie luat în discuție în diagnosticul diferențial al formațiunilor chistice parotidiene.

Particularitatea chistului dermoid parotidian raportat de noi o constituie consistența neobişnuită, lichidiană a conținutului acestuia.

CORRELATIVE ASPECTS INVOLVING HEMATOGENOUS OSTEOMYELITIS AT CHILDREN AND ADULTS (Abstract) : Osteomyelitis is an inflammation of the bone caused by an infecting organism. The infection may be limited to a single portion of the bone or may involve a number of regions such as the marrow, cortex, periostium and even the surrounding soft tissue. Material and method : This retrospective study included a number of 256 cases made by 152 children (56%) and 115 adults (44%). Results : Hematogenous osteomyelitis apears at any age, most frequently in growth period, 85% cases until 16 years. This study relieve a high frequency of subacute (40,1%) and acute (31,1%) hematogenous osteomyelitis compare with chronic form (28,8%). Regarding the distribution of cases by sex, there are no differences beetwen man and woman in chronic osteomyelitis, but subacute form is most frequently at men. The analysis of the cases distribution by location and sex relieve that at womans metaphysis and diaphysis are most interested (70,09%) but only 53,7% at men. Regarding the treatment, the distribution of cases relieve that chronic osteomyelitis generally cannot be eradicated without surgical treatment(sequestrectomy and resection followed by reconstruction with material. Those others forms, acute and subacute hematogenous osteomyelitis, were resolved with medical and surgical treatment, equaly. Conclusion : Prompt diagnosis and early treatment are required to prevent further destruction and growth disturbance. Generally, a multidisciplinary approach is requred, involving an orthopaedic surgeon, an infectious disease specialist and a plastic surgeon in complex cases with soft tissue loss. **Key words** : HEMATOGENOUS OSTEOMYELITIS, EARLY DIAGNOSIS, TREATMENT

Înainte de a defini osteomielita, trebuie să precizăm că datorită polimorfismului acestei afecţiuni este greu de sintetizat într-o singură frază tabloul clinic şi anatomo-patologic, motiv pentru care au existat de-a lungul timpului dificultăţi în elaborarea unei definiţii care să redea cât mai exact această maladie. Actualmente osteomielita acută este definită ca o infecţie acută hematogenă a osului, frecvent consecinţa unei septicemii stafilococice ; afectează cel mai adesea metafizele oaselor lungi şi se întâlneşte cu maximum de incidenţă în perioada de creştere a organismului, începând cu sugarii mici până la 14-15 ani, utilizându-se mai frecvent denumirea de "*osteomielita acută a perioadei de creştere*".

Osteomielita acută a reprezentat la copil una dintre bolile cele mai grave, până la utilizarea în practica medicală a antibioticelor mortalitatea ajungând de la 14% la 34% (Congresul Francez de Ortopedie-1932). Odată cu introducerea pe scară largă a antibioticelor s-a înregistrat o scădere reduta-

TABELUL I

bilă a mortalităţii, pentru o scurtă perioada de timp, deoarece apariţia rezistenţei la antibiotice a stafilococului auriu în special a dus progresiv la creşterea numărului de cazuri de osteomielită.

Osteomielita hematogenă (OH) are sediul preponderent în metafizele fertile ale oaselor şi din această cauză în literatură se menţionează faptul că în 75% din cazuri este interesată o metafiză „aproape de genunchi" şi în 12% de cazuri „departe de cot". Restul localizărilor se împart între extremitatea femurală superioară, extremitatea inferioară a tibiei, bazin, rar oasele scurte şi plate (1-2%). Vertebrele pot fi afectate la adult. Studii recente menţionează faptul că traumatismul este întâlnit la o treime din cazuri în istoricul bolii.

Depistarea precoce a osteomielitei hematogene duce la eliminarea erorilor de diagnostic şi tratament ce pot determina progresarea procesului patologic local la bolnavi şi asocierea complicaţiilor locale şi generale osoase, viscerale.

Deseori se constată faptul că o mare parte a copiilor s-au adresat la 2-4 zile de la debut (conform datelor de anamneză) şi au urmat tratament ambulatoriu sau staţionar la domiciliu cu diagnosticul de viroze, fracturi, entorse, artrite etc., fiind internaţi ulterior în stare extrem de gravă.

MATERIAL ŞI METODĂ

Datele de anamneză au pus în evidenţă preexistenţa frecventă a unui traumatism, pacienţii fiind trataţi ambulatoriu şi internaţi la 7–10 zile de la debut cu stare septică, leziuni osoase multiple, diseminări pulmo-

TABELUL III

nare şi cardiace. În alte cazuri s-au constatat leziuni stafilococice cutanate netratate, focare cronice de infecţie (carie dentară, amigdalită cronică etc.), care au şi fost puncte de plecare cu determinări osoase.

Debutul bolii la toţi bolnavii a fost brusc, cu stare febrilă, agitaţie, inapetenţă etc. Concomitent copiii prezentau dureri, instalate brusc, progresante cu localizare metafizară iniţial (100% cazuri), ulterior cu răspândire în regiunile învecinate, dereglarea funcţiei membrului afectat.

La momentul internării în Clinica Chirurgie Pediatrică pacienţii prezentau dureri violente continui exacerbate de mişcări neînsemnate, poziţie antalgică a membrului afectat – membrul afectat semiflectat în articulaţia de şold şi/sau genunchi în abducţie, mişcările active în articulaţiile învecinate erau reduse sau lipseau, mişcările pasive produceau dureri insuportabile. Semnele acestea au fost prezente la toţi pacienţii.

Semnele clinice locale: în primele 3–4 zile de la debut segmentul afectat a fost moderat edematiat, în următoarele zile - edem, tumefacţie circumferenţială progresantă cu răspândire în regiunile învecinate cu nuanţări de la caz la caz, cu circulaţia venoasă evidentă. La toţi pacienţii s-a probat mobilitatea membrului afectat iar palparea şi percuţia pe os produceau durere insuportabilă în 100% din cazuri.

Analiza rezultatelor examenelor de laborator a relevat, în toate cazurile, următoa-

rele schimbări : anemie de diverse grade, leucocitoză 15.000–25.000 mm^3 cu devierea formulei leucocitare spre stânga şi accelerarea VSH (30–75 mm/oră).

O parte din copiii au fost supuşi examenului radiologic. Radiografia segmentului afectat în 2 incidenţe s-a efectuat la internare la toţi bolnavii : Examenul radiologic în perioada iniţială a permis excluderea leziunilor traumatice şi diferenţierea de diverse procese patologice, iar la etapele de tratament – evoluarea procesului osteomielitic. Examenul sonografic a confirmat diagnosticul de artrită a articulaţiei învecinate segmentului osos afectat. Scintigrafia osoasă a evidenţiat modificări vasculare majore a segmentului osos afectat în toate cazurile.

Astfel, diagnosticul pozitiv s-a bazat pe : analiza detailată a datelor de anamneză, examenul clinic amănunţit al fiecărui pacient, investigaţiile de laborator şi imagistice.

Studul efectuat a evidenţiat că toţi pacienţii au fost supuşi unui tratament complex intensiv, care a constat în :

- tratament medical complex (antibiotice sub controlul antibiogramei, tratament intensiv de detoxicare cu utilizarea metodelor extracorporale de detoxicare şi reechilibrare volemică, terapie simptomatică, desensibilizantă) ;
- tratament chirurgical – intervenţie chirurgicală de urgenţă ;

TABELUL VII
Repartiţia cazurilor în funcţie de forma clinică a OS şi aspectele radiologice în lotul de studiu

	Aspect radiologic					
Forma clinică	Osteoliza metafizară	Abces subperiostic	Osteo-periostita	Abces Brodie	Sechestru osos	**Total**
Osteomelita acuta hematogena	49	20	12	0	2	**83**

- ortopedic.

Explorarea intraoperatorie a confirmat diagnosticul de OH în toate cazurile – decolarea periostului de la corticală, eliminări sub presiune din canalul osos medular, din ţesuturile moi.

Tehnica chirurgicală utilizată pentru rezolvarea procesului local a inclus paralel cu deschiderea flegmonului subperiostic, perforaţia osului, după indicaţii – puncţii a articulaţiilor învecinate (articulaţia de şold 1 –3 puncţii, genunchi 1 –2, deschiderea şi drenarea recesurilor superioare.

S-a atras mare atenţie la poziţionarea membrului afectat – poziţia fiziologică: în cazurile afectării segmentului superior – abducţie a membrului. La bolnavii cu implicarea în proces a articulaţiei de şold şi / sau a genunchiului – extensie cutanată a membrului.

Ca rezultat al aplicării tratamentului complex combinat medical, chirurgical şi ortopedic s-au obţinut rezultate favorabile cu însănătoşirea bolnavilor.

REZULTATE

Osteomielita hematogenă se întâlneşte la orice vârsta dar are maximum de frecvenţă in perioadele de creştere intensa a organismului. Acest fapt explică de ce în literatură se prezintă faptul că 85% din îmbolnăviri apar până la 16 ani (un vârf de frecvenţă sub 2 ani si al doilea intre 8 si 12 ani). Este remarcat faptul că afecţiunea prezintă o frecvenţă mai mare în rândul copiilor cu vârste până în 16 ani (56,9%) comparativ cu frecvenţă la adulţi (43,07%).

Repartiţia cazurilor din lotul de studiu în funcţie de vârstă şi forma clinică de osteomielită hematogenă

În lotul de studiu s-a remarcat frecvenţa ridicată a osteomielitei subacute hematogene (40.1%) şi a osteomielitei acute (31,1%). Aşa cum era de aşteptat, o frecvenţă mai scăzută a fost întâlnită pentru osteomielita cronică (28,8%).

În cazul osteomielitei cronice hematogene ponderea sexului masculin este comparabilă cu cea a sexului feminin, însă diferenţe semnificative apar pentru osteomielită subacută hematogenă situaţie în care cel mai frecvent este intâlnit sexul masculin (72.9%).

Distribuţia cazurilor cu osteomielită hematogenă funcţie de mediul de provenienţă şi forma clinică

Distribuţia cazurilor în funcţie de forma clinică şi mediul de provenienţă al pacienţilor cu osteomielită hematogenă evidenţiază frecvenţa diferită a cazurilor cu osteomielită hematogenă acută şi osteomielită hematogenă cronică. În aceste grupe de

pacienţi este semnificativ mai mare frecvenţa cazurilor din mediul rural (73,5% respectiv 67,5%). Pentru pacienţii cu osteomielită subacută hematogenă nu se constată o diferenţa semnificativă între numărul cazurilor din mediul urban faţă de cele din mediul rural.

Distribuţia în funcţie de forma clinică a osteomielitei hematogene şi de localizarea la nivelul osului (epifizar, diafizar, metafizar)

Pentru evidenţierea asocierii dintre forma clinică şi localizarea osteomielitei hematogene s-a realizat tabelul de contingenţă al celor două aspecte studiate (tab. IV).

Rezultatele studiului sunt elocvente evidenţiindu-se în mod clar diferenţele între localizările osteomielitei hematogene în funcţie se forma clinică a acesteia. În cazul osteomielitei acute hematogene localizarea la nivelul epifizei este foarte rar întâlnită (6,02% din cazuri), epifizar cel mai des se întâlneşte osteomielita subacută hematogenă (80,37% din cazuri). Osteomielita cronică şi cea acută se întâlnesc cel mai frecvent la nivelul diafizei sau metafizei (80,5% respectiv 93,98%).

Distribuţia în funcţie de sexul pacienţilor cu osteomielită hematogene şi de localizarea la nivelul osului (epifizar, diafizar, metafizar)

Studiul comparativ al localizării în funcţie de sexul pacienţilor cu osteomielită hematogenă a fost posibil prin realizare tabelului de contingenţă.

Analiza distribuţiei cazurilor în funcţie de localizare şi sexul pacienţilor evidenţiază prezenţa localizării pe diafiză sau metafază mai frecventă la sexul feminin 70,09% în timp ce la pacienţii de sex masculin această localizare este regăsită la 53,7% din cazuri.

Studiul formelor clinice raportate la localizarea osteomielitei hematogene la nivelul scheletului impune ca referinţă numărul total de cazuri pentru fiecare din părţile afectate ale scheletului. În acest fel s-a putut aprecia obiectiv prezenţa formelor clinice la nivelul fiecărui tip de os. Concluzia studiului constă în faptul că la nivelul oaselor lungi se regăsesc cel mai frecvent formele subacute (41,1%) în timp ce la nivelul oaselor scurte se regăsesc formele cronice (48,28%).

Rezultatele analizei indică ponderea mare a cazurilor cu osteomielită acută hematogenă localizată la nivelul humerusului (62,5%) sau cubitus/radius (60%). La nivelul tibiei cel mai frecvent a fost întâlnită forma de osteomielită hematogenă subacută (45%) în timp ce la nivelul femurului forma acută a avut o pondere asemănătoare de 44,93%.

Osteomielita cronică cel mai frecvent apare la nivelul tibiei (28,75%), la femur regăsindu-de într-o proporţie de 15,9%. Nu au fost înregistrate cazuri cu osteomielită cronică la nivelul cubitus/radius, iar pentru humerus prevalenţa a fost foarte mică de 6,25%.

Un studiu similar celui efectuat pentru oasele lungi ale scheletului a fost realizat şi la nivelul oaselor scurte, rezultatele demonstrând aşa cum era de aşteptat că şi la această grupă apar diferenţe semnificative între repartiţia cazurilor în funcţie de forma clinică şi localizare.

Referindu-ne la oasele scurte ale scheletului am constatat că cel mai frecvent osteomielita subacută hematogenă este localizată la nivelul calcaneului, toate cazurile localizate la acest nivel au fost de formă subacută (100%). Trebuie avut în vedere însă numărul mic de cazuri cu această localizare (1 caz).

Osteomielita subacută hematogenă este regăsită de asemenea frecvent la nivelul pelvisului şi al coloanei vertebrale (53,8% respectiv 54,3%).

În osteomielita cronică radiologia a evidenţiat în 54,55% din cazuri abces Brodie, în 16,8% din cazuri osteoperiostită şi în 14,29% din cazuri osteoliză metafizară. Pen-

tru această formă clinică cu o frecvenţă mai scăzută se regăsesc abcesul subperiostic (9,09%) şi sechestrul osos (2,41%). În osteomielita acută hematogenă rezultatele examenului radiologic a evidenţiat o frecvenţă mare a cazurilor cu osteoliză metafizară (59,04%) şi abces subperiostic (24,1%). Osteomielita subacută hematogenă prezintă radiologic în 68,2% din cazuri abces Brodie.

DISCUŢII ŞI CONCLUZII

Osteomielită hematogenă până în prezent rămâne una dintre cele mai grave şi frecvente infecţii chirurgicale la copil şi adult cu menţinerea la un nivel ridicat al afecţiunii, cea ce este confirmat şi în studiul nostru. Erorile de diagnostic şi tratament cel mai frecvent se produc în etapa iniţială din cauza necunoaşterii afecţiunii. Pentru un diagnostic precoce a OH, reducerea la minimum a riscului erorilor de diagnostic şi tratament în scopul îmbunătăţirii rezultatelor tratamentului copiilor cu osteomielită hematogenă este necesară elaborarea unui algoritm de diagnostic şi tratament adecvat chiar de la debutul acestei afecţiuni grave.

Procesul osteomielitic cel mai frecvent afectează femurul, cu prevalenţă segmentul superior. Pe grupe de vârstă mai afectată este vârsta 8 – 12 ani, şi cu predilecţie sexul masculin.

În studiul prezentat la etapa iniţială s-au analizat traumatismul suportat, leziunile stafilococice cutanate (focare primitive) netratate, precum şi debutul afecţiunii. Semnele locale şi generale ale OH au fost destul de caracteristice pentru OH în toate cazurile analizate: debutul brusc cu dureri locale metafizare continui progresante pe fundalul stării generale alterate şi simptomele unei infecţii grave (febră cu caracter intermitent, leucocitoză cu devierea formulei leucocitare spre stânga şi accelerarea VSH). Aceste semne s-au înregistrat la toţi copiii cu OHA din studiul nostru. Remarcăm că tabloul clinic al OHA are o specificare clasică şi permite diagnosticarea afecţiunii la debut. Analiza datelor paraclinice (imagistice) a permis confirmarea diagnosticului de OH.

Diagnosticul OH s-a realizat prin cumularea datelor anamnestice, clinice, imagistice. Pentru realizarea scopului propus printre metodele utilizate unele sau folosit ca scrining (spre exemplu: analiza datelor de anamneză, acuzelor prezentate de bolnav, manifestărilor clinice, palparea, percuţia pe os, probelor biologice - leucocitoză cu devierea formulei leucocitare spre stânga, accelerarea VSH).

Studiul efectuat a evidenţiat că toţi pacienţii au fost supuşi unui tratament complex intensiv, care a constat în tratament: medical, chirurgical de urgenţă, ortopedic. Studiul a contribuit la optimizarea diagnosticului şi tratamentului în baza utilizării în practică a algoritmilor corespunzători cu selectarea metodelor optime a tacticii curative.

THE STUDY OF AMINOPHENAZONE RADICAL CATION AND ITS INTERACTION WITH SOME ANTIOXIDANTS (Abstract): The purpose of this study was to identify both the possibilities of *in vitro* generation of 1–phenyl–2,3–dimethyl–4–dimethylamino–5–pyrazolone (aminophenazone) radical cation (abbreviated $APH^{\bullet+}$) and the mechanisms of interaction with different antioxidants. **Material and method**: The chromophore radical cation $APH^{\bullet+}$ was obtained by oxidizing APH with ammonium persulfate. The stages of the oxidation reaction and the production of the intermediate compounds were studied by spectrophotometrical and potentiometric titration. As standard antioxidant there was used a catechin solution in distilled water with concentrations ranging between 50–250 μg/mL, in weak alkaline environment. **Results**: The oxidation of APH with ammonium persulfate developed in four stages, involving the production of some intermediate compounds with different colorations. A mechanism for this reaction has been proposed. The radical cation forms to an APH – ammonium persulfate molar ratio of 2 : 1. In the presence of an antioxidant (catechin) the radical cation $APH^{\bullet+}$ forms to a molar ratio APH–ammonium persulfate of 1 : 1, in weak alkaline environment. It has an absorbtion maxima at λ = 540 nm. The molar extinction coefficient of $APH^{\bullet+}$ at λ = 540 nm has been calculated. Its absorbance was proportional with catechin concentration in the range 50–250 μg/mL (r^2 = 0.9988). **Conclusion**: The APH–ammonium persulfate system can be used for spectrophotometric determination of total polyphenols in different systems. **Key words**: AMINOPHENAZONE, RADICAL CATION, ANTIOXIDANT, CATECHIN

The methods used for measurement of *in vitro* antioxidant activity are based on direct quantification of antioxidants in different systems or on measuring the ability of an antioxidant to scavenge free radicals generated through controlled chemical oxidation of some easily oxidable compounds.

As stable chromophore radicals there are widely used 2,2'–azinobis–(3–ethylbenzo– thiazoline–6–sulfonic acid) (ABTS) and 2,2'–diphenyl–1–picrylhydrazyl (DPPH).

The spectrophotometric methods using these radicals measure the reduction of the radicals by an antioxidant, calculated as percentage inhibition of absorbance.

Trolox, a synthetic derivative of vitamin E, is the most often used antioxidant; the antioxidant activity is expressed as TEAC (Trolox Equivalent Antioxidant Capacity), term that reflects the ability of the antioxidant to donate protons or electrons to scavenge the $ABTS^{\bullet+}$ radical, relative to the reactivity of Trolox as a standard (1–5).

These methods were used to determine antioxidant activity of foods, cosmetic products, biological liquids (6–9).

The aim of our research was to generate a new chromophore radical and to study the parameters that influence its stability in order to use oxidation intermediates as de-

TABLE I
Maximum absorbtion of the main oxidation products of APH with $(NH_4)S_2O_8$

Product	Reaction time (minutes)	Colour	$ë_{max}$ (nm)
P_1	1	Blue	600
P_2	3	Violet	580
P_3	15	Red	540
P_4	30	Yellow	355

tection system for spectrophotometric assay of total phenolic content.

MATERIAL AND METHOD

The reagents used in the study of oxidation reaction of aminophenazone were: 1–phenyl–2,3–dimethyl–4–dimethylamino–5–pyrazolone (aminophena– zone – APH), ammonium persulfate – $(NH_4)_2S_2O_8$, catechin (trans–3,3',4',5,7–pentahydroxy flavan) with analytical purity and $NaHCO_3$ solution 5%.

The stoichiometry of APH with $(NH_4)_2S_2O_8$ oxidation reaction was carried out by spectrophotometric and potentiometric titration. The spectrophotometric titration was performed with a Hewlett Packard 8453 series UV–VIS spectrophotometer and the potentiometric titration was performed with an electronic pH–meter Seibold Wien, using the platinum electrode as the indicator electrode and the calomel electrode as the reference electrode.

RESULTS

The oxidation of APH with $(NH_4)S_2O_8$ developed in several stages, involving the production of intermediate compounds with different colorations: blue, violet, red, yellow.

The absorbtion spectrum showed the values of wavelengths where the absorbance of the intermediate products was highest (tab. I).

It has been determined the molar combination ratio APH : $(NH_4)S_2O_8$ through spectrophotometric titration for three of the main products (tab. II).

Through potentiometric titration of 0.1 M APH with 0.1 M $(NH_4)S_2O_8$ there has been established that the molar ratio APH : $(NH_4)S_2O_8$ in red compound is 2 : 1.

There has been studied APH interaction with some antioxidants, in order to obtain a detection system for the antioxidant activity. It has been found that polyphenols (catechins) react with APH in the presence of $(NH_4)S_2O_8$ [APH : $(NH_4)S_2O_8$ molar ratio of 1 : 1] in weak alkaline medium (pH=8–9), forming a red–orange compound, with maximum absorbance at λ = 540 nm.

A linear increase of the absorbance with increasing amounts of catechin was observed in the range 50–250 μg catechin/mL, respectively 0.216–1.080 μmols; correlation coefficient R^2=0.9988 (fig. 1).

Standard error of regression line (SE) = 0,009343; detection limit (DL) = 0,1884 μg/mL and limit of quantification (LOQ) = 0.6281 μg/mL

DISCUSSIONS

Previous researches have established that the intermediate product with red colour (P_3) is a radical cation. Its radicalic structure was determined by isolating the compound under the form of spin aduct through its precipitation with silicotungstic acid and analyzed through electron spin resonance (ESR).

From the experimental data we can conclude that the oxidation reaction of APH develops in several successive stages (fig. 2). In these reactions APH appeared as Ant. $N(CH_3)_2$.

In the first step APH is oxidized with

TABLE II
Molar ratio APH : $(NH_4)S_2O_8$

Volume of 0.01 M APH (mL)	ë (nm)	Volume of 0.01 M $(NH_4)S_2O_8$ at equivalence point (mL)	Molar ratio APH:$(NH_4)S_2O_8$
5.00	600 (P_1)	5.00	1:1
5.00	540 (P_3)	2.50	2:1
5.00	355 (P_4)	2.50	2:1

$$Ant.N(CH_3)_2 \overset{-2e}{\rightleftharpoons} Ant.\overset{+}{N}(CH_3)_2$$
$$P_1$$

$$Ant.\overset{+}{N}(CH_3)_2 + Ant.N(CH_3)_2 \rightleftharpoons 2Ant.\overset{\bullet+}{N}(CH_3)_2$$
$$P_3$$

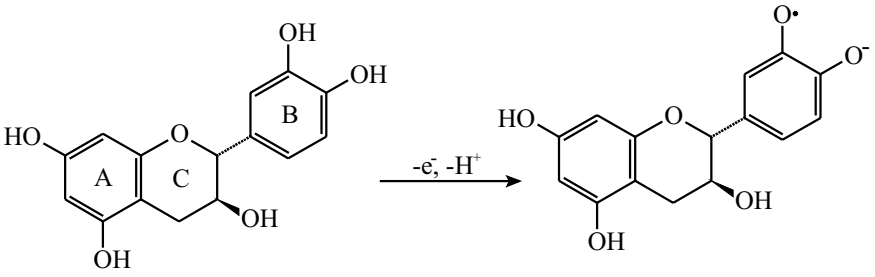
Fig. 2. Mechanism of oxidation of APH

the two electron change (P_1 – blue compound).

In the second stage, another molecule of APH reduced P_1 compound, forming a radical cation $APH^{\bullet+}$ (P_3 – red compound).

In the third stage, probably, a dimerization of cationic radical (P_4 – yellow compound, stable) took place.

(+)–Catechin is involved in the second stage of the reaction, reducing APH^+ cation formed within the first stage to the red colored radical cation $APH^{\bullet+}$. (+)–Catechin is oxidized to semiquinone anion radical with donation of one electron and one



(+)-catechin semiquinone

Fig. 3. Mechanism of oxidation of catechin

proton from B ring (10,11) (fig. 3).

The reaction between catechin and APH is sensible ; the molar extinction coefficient $\varepsilon = 7.32 \cdot 10^2$ $mol^{-1} \cdot L \cdot cm^{-1}$.

The colored compound is very stable. The proposed method is applicable for quantification of total polyphenols, expressed in catechin, from different environments.

CONCLUSIONS

In this study we suggest a method for generating $APH^{\bullet +}$ radical cation, with the purpose of using it for the quantitative determination of several antioxidants. The reaction that takes place between (+)–catechin and APH in the presence of $(NH_4)_2S_2O_8$ in alkaline media generates a red colored radical cation. The absorbance of the solution is proportional to the concentration of catechin.

The optimal conditions for applying this reaction to spectro–photometrically quantification of total polyphenolic content in different products have been established.

EARLY CHILDHOOD CARIES. EPIDEMIOLOGICAL CONSIDERATIONS (Abstract): **Aim**: To asses the current demographic tendencies of the carioactivity, in Iaşi area, especially ECC and S-ECC. **Material and methods**: Study group included 500 subjects (276 girls and 224 boys), 3-6 years of age, 70% urban and 30% rural. The oro-dental evaluation was achieved through clinical investigation, based on criteria and markers recommended by WHO, the estimation of the indices of the caries prevalence: caod, cao, SIC, ICDAS, pshychological assesment and sociological investigation using interviews and questionnaires. Recorded data were used for statistical analysis in SPSS 17 trial, in visual FOX-PRO9. **Results**: The hole assessment showed a low caries risk (83.3%), compared to the values of the medium caries risk (9.2%), and of the high caries risk (7.5%). In term of clinic variability, the normal carial pattern is frequent, followed by atypical carial patterns, ECC and S-ECC, with differences between genders (boys – 1.91, girls – 1.99). In relation to the socio-econimic level of the family, the cao index varies: cao-1 - high socio-economic level, cao-1.46 - medium socio-economic level, cao-2.87 - low socio-economic level. **Conclusions**: The values of the epidemiologic indices, showed a variability of the carioactivity of the temporary dentition, with growth of the atipical carial patterns, ECC and SECC. The above mentioned aspects require to reconsider the view points on temporary dentition and the promotion of an educational and prevention programme.
Key words: CHILD, DENTAL CARIES, TEMPORARY DENTITION, ECC, SECC, EDUCATION, PREVENTION

Caria dinţilor temporari reprezintă o problema majoră de sănătate oro-dentară cu care se confruntă copilul preşcolar.

În acest cadru de referinţă, caria timpurie (ECC), dar mai ales caria severă timpurie (SECC), au o semnificaţie aparte, prefigurându-se ca o problemă de sănătate publică pe plan mondial, cu particularizări pe plan zonal, ale prevalenţei şi variabilităţii clinice, mai ales în ţările în curs de dezvoltare (1).

În 1994, European Centres for Diseases Control and Prevention, delimitează prin termenul de carie timpurie, ''orice formă de carie la copii, ce reflectă un proces etiologic, multifactorial implicat în boală'' (2).

Caracterul, relativ restrâns, al informaţiilor existente în aceasta direcţie se motivează, după cum menţionează Horowitz în 1998, prin accesibilitatea de examinare limitată şi dificultatea de evaluare clinică stomatologică al copilului din comunităţile preşcolare şi îndeosebi din comunităţile ante-preşcolare (3,4,5,6,7).

Majoritatea studiilor de referinţa sunt focalizate preponderent pe etapa de vârsta 5 ani, pe grupuri populaţionale relativ mici şi pe tiparele dentare maxilare anterioare

(4,6,7). Marthaler et al. (1996), Peterson şi Brathall (1996), Tinanoff et al. (2002) semnalează o creştere polarizată a experienţei cariale la nivelul populaţiilor preşcolare în ţările vest europene (prevalenţa globală fiind sub 5%) (7).

Poulsen în 2002, în contextualitatea ţărilor nordice, afirmă că 5-10% dintre copiii sub vârsta de 3 ani, au carii dentare şi o mare proporţie a acestor leziuni, chiar şi cele necavitare, reprezintă un risc înalt de progresie carială cavitară la vârsta şcolară.

În SUA, Horowitz semnalează încă din 1998 o prevalenţă a ECC de 3-6% (8,9,10).

În România, primele studii referitoare la ECC sunt efectuate de Zarnea şi Luca în 1987 (4). Ca relevanţă zonală reţin în mod deosebit atenţia studiile efectuate după 1990 : Cocarla et al. (Cluj-1993), Dorobăţ et al. (Iaşi, 1994), Luca et al. (Bucureşti, 2001), Dănilă et al. (Iaşi, 2004-2007).

Obiectivul acestui studiu urmăreşte evaluarea în dinamică la nivel zonal Iaşi a tendinţelor demografice (epidemiologice) actuale a carioactivităţii dentaţiei temporare, în mod deosebit a ECC şi a SECC, precum şi interrelaţia cu modelul familial şi comunitar.

Scopul studiului este de a socializa şi modela comportamental copilul preşcolar privind sănătatea oro-dentară, bazat pe un concept social şi un model medical de management stomatologic pediatric.

MATERIAL ŞI METODĂ

În argumentarea scopului propus am efectuat un studiu complex, „cross-sectional", pe un lot de 500 de subiecţi (276 fete şi 224 băieţi), cu limita de vârstă între 3 şi 6 ani, cu un procentaj de 70% din mediul urban şi 30% din mediul rural, cu apartenenţă familială şi comunitară variate.

În strategia de studiu s-a urmărit standardizarea metodologiei de lucru, prefigurarea şi derularea studiului pe parte integrativă a componentei zonale promovată de Disciplina de Dentistică Preventivă în cadrul Programului Naţional actual de Prevenire a afecţiunilor oro-dentare la copil, identificarea necesarului de resurse şi infrastructură, evaluarea interdisciplinară a subiecţilor, organizarea la nivelul comunităţilor preşcolare monitorizate a cursului interactiv ''teaching the teachers'', aplicarea flexibilă a programului educaţional preventiv şi interceptiv, atât la nivel comunitar cât şi la nivelul bazei clinice.

Evaluarea oro-dentară s-a realizat prin investigarea clinică bazată pe criterii şi markeri, recomandaţi de O.M.S., estimarea indicilor de prevalenţă carială : caod, caos, SIC, ICDAS, evaluare psihologică şi anchetă sociologică - prin interviu şi chestionare cu întrebări deschise şi închise.

În prelucrarea datelor statistice s-a utilizat programul SPSS-17 în Visual FOX PRO 9, teste statistice : Anova, Chi-patrat, Fischer, Curba ROC şi regresia linear multiplă R1 şi R2.

REZULTATE ŞI DISCUŢII

Pentru a cuantifica interrelaţia între riscul carios şi variabilele de clasificare am calculat coeficientul de contingenţă. Global, am remarcat preponderenta unui risc carios mic (83,3%), comparativ cu valorile scăzute ale riscului carios mediu (9,2%) şi ale riscului carios mare (7,5%), cu o reprezentare graduală în raport cu etapa de vârstă (fig. 1). În ceea ce priveşte riscul carios, comparativ pe sexe, am putut re-

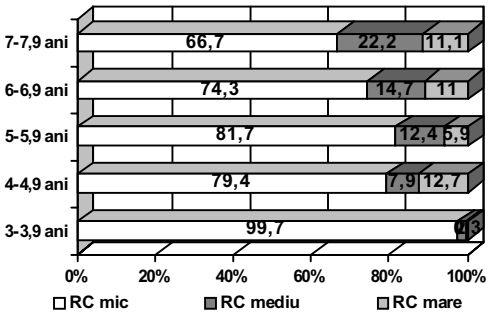

Fig. 1. Riscul carios pe grupe de vârstă

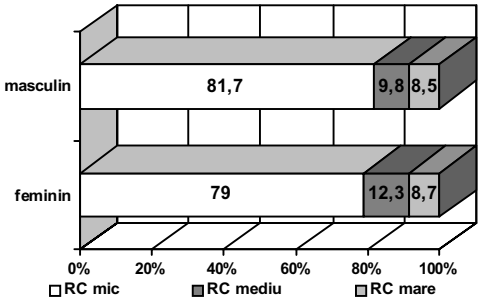

Fig. 2. Valorile riscului carios comparativ pe sexe

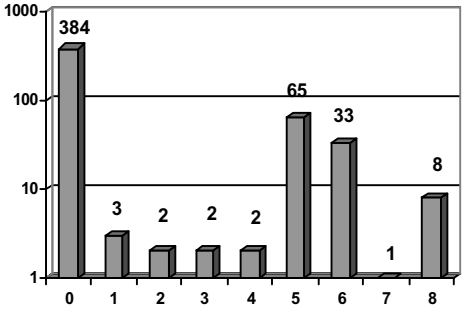

Fig. 3. Evoluţia indicelui cao în raport cu statutul socio-economic

TABELUL I

Valorile indicelui cao şi a indicelui sic pe grupe de vârstă

	C+A+O	Nr. cazuri	Valoare	Indice SIC
Indicele CAO global	979	500	**1.958**	**0.250**
Valorile pe intervale de vârstă				
între 3 – 3,9 ani	37	43	**0.860**	**0.100**
între 4 – 4,9 ani	271	126	**2.151**	**0.280**
între 5 – 5,9 ani	354	186	**1.903**	**0.240**

marca, existenţa unui risc carios mic cu un nivel mai ridicat la băieţi, 81,7%, în comparaţie cu fetele, 79%, un risc carios mediu cu un nivel mai ridicat la fete, 12,3%, în comparaţie cu băieţii, 9,8%, şi un risc carios mare cu un nivel mai ridicat la fete, 8,7%, în comparaţie cu băieţii, 8,5% (fig. 2.)

În mediul rural predomină un risc carios mic, iar în mediul urban riscul carios este moderat.

În raport cu dinamica etapelor de vârstă, am remarcat o evoluţie vizibil ascendentă a carioactivităţii dentaţiei temporare, aspect ce se prefigurează ca potenţial predictor carial pentru dentaţia permanentă.

Pentru grupa de vârsta 3-4 ani am găsit un indice cao de 0,86, iar la grupa de vârstă 4-5 ani un indice cao de 2,15 comparativ cu indicele cao de 1,34 semnalat de Dănila et al. în perioada 2004-2007, la nivel zonal Iaşi pentru etapele de vârstă 2,5-5 ani, şi un indice mai mic decât indicele cao surprins în 2001 de Luca et al. la nivel zonal Bucureşti, respectiv 3,98.

Sub aspectul variabilităţii clinice, se prefigurează alături de tiparele cariale convenţionale tot mai des tiparele atipice, cu predominanţa carie timpurie şi carie severă timpurie, cu uşoare diferenţieri nesemnificative statistic între cele două sexe (băieţi - 1,91, fete - 1,99).

În raport cu nivelul socio-economic al familiei aparţinătoare indicele cao se nuanţează astfel : cao 1 - în contextul nivelului socio-economic ridicat, cao 1,46 - nivel socio-economic mediu, cao 2,87 - nivel socio-economic scăzut (fig. 3).

Valorile indicelui sic pe etape de vârstă atesta trendul epidemiologic actual al carioactivităţii dentaţiei temporare la nivel

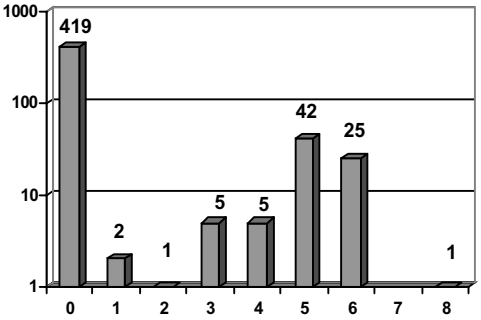

Fig. 4. Valoarea indicelui ICDAS pentru molarul doi temporar 65

zonal Iaşi.

Cu o semnificaţie deosebită, atât retrospectiv cât mai ales ca predictibilitate dento-dentară, cât şi dento-alveolară, ne apar valorile indicelui ICDAS (International Caries Dental Assesment) pentru molarii doi temporari, cu variabile diferenţieri, atât între cele doua maxilare, cât şi între cele patru cadrane (fig. 4).

CONCLUZII

Trendul epidemiologic actual al carioactivităţii dentaţiei temporare şi îndeosebi al ECC constatat de noi, în zona Iaşi, ilustrează „omniprezenţa factorului de risc major" (11) asupra stării de sănătate orodentară şi psiho-somatică, implicit asupra calităţii vieţii copilului.

Valorile indicilor epidemiologici relevă o variabilitate a carioactivităţii dentaţiei temporare, cu emblemarea ascendentă a ECC şi SECC.

Departajările valorice ale indicelui ICDAS sunt edificatoare în ceea ce priveşte dinamica epidemiologică şi clinică a ECC şi SECC.

Aspectele menţionate impun: reconsiderarea opticii privind dentaţia temporară, promovarea unui program educaţional şi de prevenţie stomatologică pediatrică primară, realist, efectiv şi flexibil, coparticipativ, accesibil tuturor copiilor la nivel comunitar.

PREVENTION OF SPINAL DISORDERS IN DENTISTRY (Abstract): Professional activity in dentistry account for excessive request of the spine and peripheral joints. **Material and method**: We performed an observational prospective study on ten physicians (six women, four men) aiming to evaluate the time used in vicious positions during a working day and to establish a specific kinetic program directed to relaxation and rebalancing lumbo-abdomino-pelvic muscles. The working time in a typical day either using orthostatic or sitting position was assessed according to a standard protocol. **Results**: Left dorsal scoliosis with rotation lasting over 97 minutes of daily working time, sinistro-concave dorsal scoliosis with a typical duration of 42.5 minutes, dextro-concave kyphoscoliosis with a mean time of 37 minutes and dorsal scoliosis with right rotation lasting 31 minutes were reported. Moreover, both left and right rotations were demonstrated during the working time accounting for about 22.5 minutes and 29 minutes respectively, while a lesser time deal with the side of right-left uncombined movement. **Conclusion**: Almost three quarters of working time (71%) takes place in vicious positions, suggesting that, unfortunately, the ergonomic position is seldom maintained in current dentistry practice. A complex rehabilitation program is therefore mandatory in order to prevent muscle imbalance. **Key words**: DENTIST POSTURE, BACK PAIN, ERGONOMIC POSTURE

SYNTHESIS AND EVALUATION OF ANTIOXIDANT ACTIVITY OF SOME HYDRAZONES WITH XANTHINE STRUCTURE

SYNTHESIS AND EVALUATION OF ANTIOXIDANT ACTIVITY OF SOME HYDRAZONES WITH XANTHINE STRUCTURE (Abstract): **Aim:** To synthesize some hydrazones with xanthine structure and to evaluate their antioxidant activity. **Material and methods:** The synthesis started from theophylline sodium salt, prepared from theophylline and sodium methoxide, which was transformed into its ethyl ester and then in hydrazide. The hydrazone derivatives were obtained by the condensation of hydrazide with different aromatic aldehydes (benzaldehyde, 4-nitro/3-nitro/3-hydroxy/4-chloro/4-bromo-benzaldehyde). The antioxidant potential was evaluated *in vitro* by using the DPPH radical scavenging assay and was compared with theophylline activity used as parent compound. **Results:** Six hydrazones with xanthine structure were obtained. They were characterized in terms of their physical properties and their structures were confirmed by IR and ^{1}H-NMR spectroscopy. Some of these compounds have an antioxidant effect more pronounced than theophylline at higher concentrations. The most active compound was 3-nitro-benzylidene-hydrazino-acetyl-theophylline (compound g), with an inhibition rate of 65% ± 0.99 at 30 min and 79% ± 0.81 at 60 min. **Conclusions:** The antioxidant activity of synthesized hydrazones depends on the substituents used in structural modulation. The substitution of aromatic ring with nitro group in *meta* position had the most favorable influence. **Keywords:** THEOPHYLLINE, HYDRAZONE, ANTIOXIDANT ACTIVITY, DPPH.

Xanthine structure is known for its important biological effects and could be found in the structure of compounds with vasodilator, bronchodilator, anticancer, anti-inflammatory and hypoglycemic action (1). The most important compounds with xanthine structure are caffeine, theophylline and theobromine (2). Theophylline is used for the treatment of essential asthma, asthmatic dyspnea and bronchopulmonary disease. The xanthine moiety is present also in the structure of Linagliptin (Tradjenta®, Trajenta®), a DPP-4 inhibitor used for the treatment of diabetes mellitus type 2 (3).

On the other hand, there is increasing evidence supporting the involvement of oxidative stress in such diseases as atherosclerosis, diabetes, cancer, glaucoma, rheumatoid arthritis, psoriasis and Alzheimer disease (4). Oxidative stress is an imbalance between production of harmful reactive oxygen species such as free radi-

cals or peroxides named oxidants and the ability of the body to fight with their effects using different endogenous antioxidants (5).

The main objective of this study was the synthesis of some hydrazones with xanthine structure and the evaluation of their potential antioxidant activity.

MATERIAL AND METHODS

Reagents. Theophylline, sodium, ethyl chloroacetate, hydrazine hydrate 64%, aromatic aldehydes (benzaldehyde, 4-nitro/3-nitro/3-hydroxy/4-chloro/4-bromo-benzaldehyde), organic solvents (methanol, ethanol, dimethyl formamide - *p.a.* quality) and standard reagents for antioxidant assay were purchased from Sigma Aldrich Company. All reagents and solvents were used without previous purification. For monitoring the reactions Thin Layer Chromatography (TLC) Silica gel 60 F_{254} plates produced by Merck Company were used. The Proton Nuclear Magnetic Resonance (^{1}H-NMR) spectra were obtained in dimethyl sulfoxide deuterated (DMSO-d_6) produced by Sigma Aldrich Company.

Chemistry. The synthesis of compounds started from theophylline sodium salt (b), which was obtained from theophylline (a) and sodium methoxide, prepared from sodium and dry methanol. In the next step, the sodium salt reacted with ethyl chloroacetate when theophylline-ethyl acetate (c) was formed. Then, the resulted ester was treated with an excess of hydrazine hydrate (64%) (6-8) to obtain hydrazide (d), which, by condensation with different aromatic aldehydes (benz-aldehyde, 4-nitro/3-nitro/3-hydroxy/ 4-chloro/ 4-bromo-benzaldehyde), formed the corresponding hydrazones (e-j) (fig. 1).

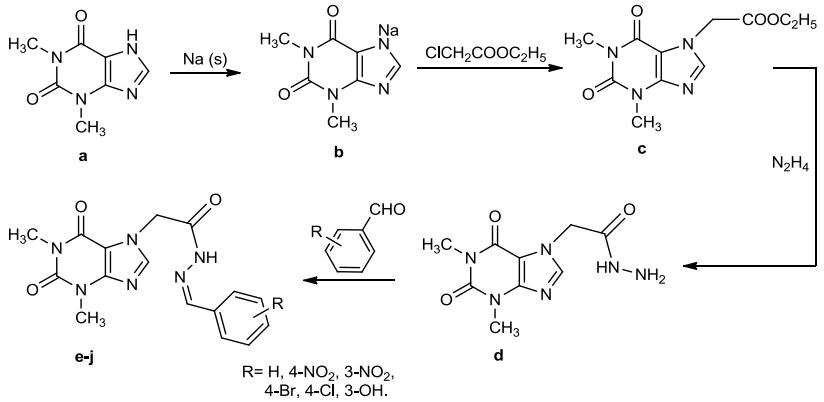

Fig. 1. The synthesis of hydrazone derivatives with xanthine structure.

General procedure for synthesis of hydrazones with xanthine structure

Theophylline-ethyl acetate (c). To a solution of sodium methoxide freshly prepared from sodium (0.1 mol) and dry methanol (200 mL), theophylline (0.1 mol) was added in small parts. The reaction was carried out at room temperature with stirring until all the solvent was evaporated. The resulted theophylline sodium salt (0.1 mol) was added to a mixture of ethanol: dimethyl formamide (DMFA) (260 mL: 100 mL). The mixture was heated under reflux and stirred for 1 h and after that

ethyl chloroacetate (0.1 mol, 10.71 mL) was added dropwise and left refluxing overnight. The ethyl ester was recrystallized from ethanol. The reaction was monitored by TLC using dichloromethane: methanol = 9.6: 0.4 as eluent system.

Theophylline-hydrazide (d). The ethyl ester of theophylline (0.035 mol) in ethanol (50 mL) was heated under reflux and stirred until solubilization and then hydrazine hydrate 64% (0.11 mol, 5.52 mL) was added dropwise. The extra amount of ethanol (150 mL) was added and the mixture was heated under reflux for 6 h. The reaction was monitored by TLC using ethyl acetate: acetone =7.5:3 as eluent system. The product was separated by filtration and washed two times with diethyl ether.

Theophylline-hydrazones (e-j). A mixture of acetyl-theophylline-hydrazine (0.006 mol) and ethanol (200 mL) was refluxed for 1 h. Some drops of glacial acetic acid and the aromatic aldehyde (benzaldehyde, 4-nitro/ 3-nitro/ 3-hydroxy/ 4-chloro/ 4-bromo-benzaldehyde) (0.009 mol) were added and the mixture was refluxed for 4-24 h with continuous stirring. The reaction was monitored by TLC using ethyl acetate: acetone =7.5:3 as eluent system. The resulted hydrazones were purified by filtration and washed two times with diethyl ether and n-pentane.

Spectral characterization. Fourier transform infrared (FT-IR) spectra were recorded on a Nicolet iS50 FT-IR Spectrometer, at a resolution of 4 cm^{-1} after 16 scans in the 4000-600 cm^{-1} range. The spectra were interpreted using Omnic Spectra Software. ^{1}H-NMR spectra were recorded using a NMR Bruker 400 MHz spectrometer (Germany).

Antioxidant assay

DPPH radical scavenging activity. In order to evaluate the antiradical capacity against DPPH radical, the hydrazone derivatives (e-j) were dissolved in DMSO to obtain a stock solution with a concentration of 25 mg/mL. From the stock solution different volumes (50 µL, 100 µL, 150 µL, 200 µL, 250 µL, 300 µL) were taken and diluted with DMSO in order to obtain 400 µL. The sample solution (400 µL) was added to 2.5 mL solution of DPPH in methanol 0.1 mM and the mixture was left in the dark. After 30 min and 60 min, respectively, the absorbance was measured at 517 nm against a blank (methanol) using a UV-VIS spectrophotometer (9, 10). The DPPH radical scavenging activity was expressed as percentage according to the following equation: % Inhibition = $(A_0 - A_1)/A_0 \times 100$, where

A_0= absorbance of the control (solution of DPPH in methanol);

A_1= absorbance of the sample at 30 min and 60 min respectively.

Statistical analysis. All experiments were performed in triplicate and the data were analyzed using the analysis of variance and were expressed as arithmetic mean ± standard deviation (SD).

RESULTS AND DISCUSSION

Chemistry

Theophylline-ethyl acetate (c) is colorless or white needle crystals, with melting point (m.p.) = 137-140 ºC, soluble in ethanol on heating.

The hydrazide of theophylline (d) is a white powder, very electrostatic, with m.p.=272-275 ºC, soluble on heating in DMSO and a mixture of acetone and few drops of water.

The hydrazones with xanthine structure (e-j) are fluffy solid compounds, with small density and cotton structure. They have electrostatic properties. The compounds are white or yellow in color. They are soluble in a mixture of acetone and few drops of

water, DMSO and DMFA on heating, partially soluble in methanol on heating, slightly soluble in chloroform, insoluble in absolute ethanol (tab. I).

TABLE I

Physical characteristics of hydrazones with xanthine structure (e-j)

Comp.	R	Formula	Molecular weight	Appearance (solid)	M.p. (°C)	Yield (%)

The structure of the final compounds was confirmed by FT-IR and ^{1}H-NMR spectroscopy (tab. II). Hydrazone derivatives (e-j) were obtained in two tautomer forms, the second form being in the ratio of 20-25%. The presence of the tautomer

forms was demonstrated using ^{1}H-NMR-temperature at 80 ºC.

Antioxidant assay

DPPH radical scavenging activity. The evaluation of antioxidant activity was performed by measurement of radical scavenging ability of the compounds against free radicals such as 2,2-diphenyl-1-picrylhydrazyl (DPPH), superoxide anion radical, hydroxyl radical or 2,2-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) cation radical ($ABTS^{+\cdot}$) (11). The DPPH assay is the most used method to evaluate the antioxidant activity. This method evaluates the hydrogen atom donating activity using the spectrophotometric measurement of the radical concentration. DPPH is a purple-colored organic nitrogen radical, which changes its color to pale yellow upon a reduction reaction with hydrogen donating compounds (fig.2). The decrease in optical density expresses a measure of antioxidant activity (12) (tab. III, IV).

It can be observed that the most active compound is compound g, which has as substituent on aromatic ring the *nitro* group in meta position. For this compound the inhibition rate (%) ranged from 31% to 65% (at 30 min) and from 44% to 79% (at 60 min), depending on sample concentration (0.431 mg/mL, 0.862 mg/mL; 1.293 mg/mL; 1.724 mg/mL; 2.155 mg/mL; 2.586 mg/mL). The antioxidant activity of compound g was 2-3 times higher than that of theophylline, used as parent compound (fig. 3, 4). These results support the favorable influence of chemical modulation on radical scavenging ability. The other compounds have an inhibition percentage almost equal to that of theophylline at small concentrations (0.431 mg/mL, 0.862 mg/mL, 1.293 mg/mL), but at higher concentrations the antioxidant effect was more pronounced.

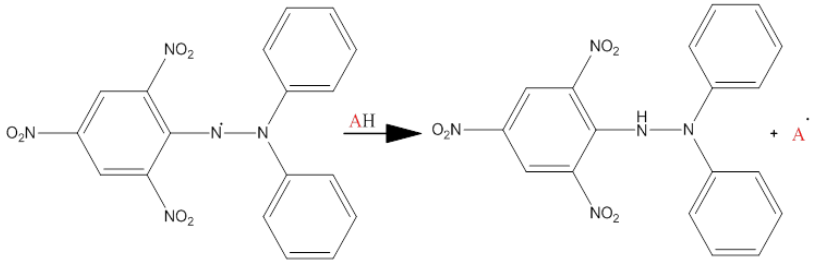

Fig. 2. The reduction reaction of the DPPH.

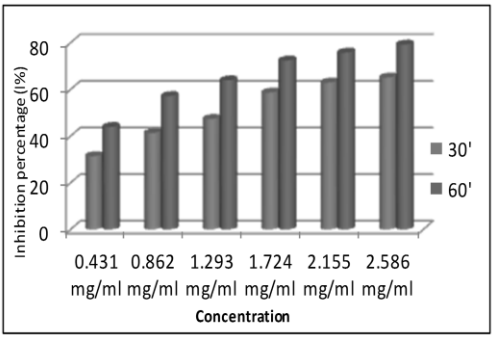

Fig. 4. The antiradical effect of compound g at different concentrations

CONCLUSIONS

In our studies, six hydrazones with xanthine structure have been synthesized starting from theophylline, a substance known for its beneficial effects, especially as bronchodilator agent. The resulted compounds were characterized in terms of their physical properties (chemical formula, molecular weight, yield, melting point, solubility in different organic solvents, etc.). Their structure was confirmed by FT-IR and ^{1}H-NMR spectroscopy. The antioxidant activity of the synthesized compounds was evaluated *in vitro* using the DPPH radical scavenging assay. Compound g (3-nitrobenzylidene-hydrazino-acetyltheophylline) was the most active compound, with the highest inhibition rate compared with theophylline.

ISOLATION, CHARACTERIZATION AND ANTIOXIDANT ACTIVITY OF THE CRUDE POLYSACCHARIDE FROM *PHYLLOPHORA PSEUDOCERANOIDES* (Abstract): The red seaweed *Phyllophora pseudoceranoides* (Gmelin) New. et Tayl, commonly found in the Romanian Black Sea coastal waters, has not been studied regarding its chemical composition and biological activities. **Aims**: The aim of the present study was to isolate, characterize and assess the *in vitro* antioxidant activity of the crude polysaccharide from *P. pseudoceranoides*. **Materials and Methods**: The water soluble polysaccharide was characterized by Fourier transform infrared spectroscopy (FT-IR). Total phenolic content was determined by Folin-Ciocalteu method. Antioxidant activity was evaluated by ABTS radical cation scavenging and reducing power assays. Commercial-grade carrageenan was used as positive control. **Results and Discussion**: FT-IR analysis of the crude polysaccharide showed characteristic bands of carrageenan-type structure. A total phenolic content of 25.08 ± 1.00 mg GAE/g was determined in the crude polysaccharide. At 1.5 mg/mL, the polysaccharide exhibited important ABTS scavenging activity (49.59 ± 0.03%) and showed a good reducing power (0.4060 ± 0.002), when compared with the positive control (ABTS scavenging activity: 30.30 ± 0.03% and reducing power: 0.2494 ± 0.002, at a concentration of 1.5 mg/mL). **Conclusions**: The antioxidant activity of the sulfated polysaccharide suggests its possible use as an ingredient and antioxidant agent in the food and pharmaceutical industries. **Keywords**: *PHYLLOPHORA PSEUDOCERANOIDES*, POLYSACCHARIDES, ALGAE, ANTIOXIDANT ACTIVITY.

Over the past decades, marine macroalgae have attracted an emerging interest due mainly to their bioactive constituents with a broad spectrum of activities (1). Carrageenans are linear sulfated galactans extracted from red algae; these phycocolloids are classified according to the number and position of sulfated groups, the presence of

3,6-anhydro-D-galactose and the conformation of the pyranose ring, resulting six groups: iota (ι)-, kappa (κ)-, lambda (λ)-, mu (μ)-, nu (ν)- and theta (θ)- carrageenans, the first three carrageenans being of commercial interest (fig. 1). Carrageenans are used in the food industry as thickening and gelling agents, but also in the non-food industries such as the pharmaceutical, cosmetics, printing and textile industries. Furthermore, carrageenans might be used in the development of new therapeutic agents, as they are endowed with anticoagulant, antiviral, antioxidant, antitumor, immunomodulatory and cholesterol-lowering properties (2).

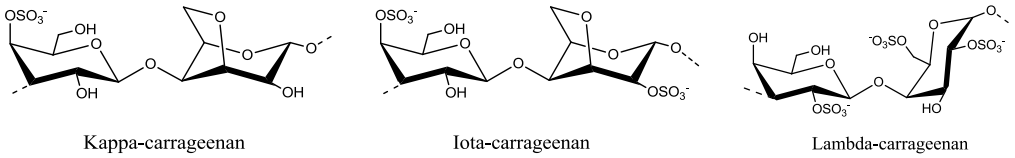

Fig. 1. Chemical structures of carrageenans

Research in the field of antioxidants from macroalgae has gained considerable attention, as these metabolites can delay or inhibit the effects of reactive oxygen species (ROS) in biological systems (3). It is known that increased ROS generation leads to DNA damage, lipid peroxidation and protein denaturation, playing a key role in the etiology and pathogenesis of a wide range of diseases and age-related disorders (4). Furthermore, as the extensive use of synthetic antioxidants (butylhydroxytoluene, butylhydroxyanisole, propyl gallate and tert-butylhydroquinone) has been associated with potential health risks (5), seaweed polysaccharides could offer a natural alternative to synthetic antioxidants by enhancing the safety and preserving the quality of foods (3).

Phyllophora pseudoceranoides (Phyllophoraceae) is a red seaweed, commonly found in the coastal areas of the Romanian Black Sea. The aim of this study was to isolate and characterize the crude polysaccharide from *P. pseudoceranoides*; in addition, the total phenolic content and *in vitro* antioxidant activity were investigated in order to assess its potential use in the field of food and pharmaceutical industries.

MATERIAL AND METHODS

Chemicals

Carrageenan (commercial grade, type I), gallic acid, potassium ferricyanide, iron (III) chloride and sodium carbonate were purchased from Sigma-Aldrich (Steinheim, Germany). 2,2'-Azinobis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium salt (ABTS), disodium phosphate dodecahydrate and Folin-Ciocalteu's phenol reagent were supplied by Fluka (Steinheim, Germany). Monopotassium phosphate was purchased from Merck (Darmstadt, Germany). Trichloroacetic acid and potassium persulfate were purchased from Riedel-de Haën (Seelze, Germany). All other solvents and reagents were of analytical grade.

Algal material

Phyllophora pseudoceranoides was collected along the Black Sea coastal areas of Romania in June 2014 (location: Constanta - 44°11'44"N, 28°39'24"E). A voucher specimen was deposited in the Laboratory of Pharmacognosy, Faculty of Pharmacy, University of Medicine and Pharmacy

Grigore T. Popa - Iasi. Fresh seaweed material was washed thoroughly with distilled water to remove salt and sand; the air dried sample (40 ºC) was powdered and kept at -4 ºC until analysis.

Isolation of the crude polysaccharide

Algal material was first extracted with ethanol to remove pigments and polyphenols; then, the residue was dried and extracted with ultrapure water (1.5% w/v) for 2 h at 100 ºC. After filtration and concentration of the aqueous extract, the polysaccharide was isolated by precipitation with ethanol (1:3 v/v); the precipitate was washed with acetone and air dried. Then, the polysaccharide was re-dissolved in ultrapure water, followed by the same protocol of precipitation, washing and drying (6). The final precipitate was lyophilized, giving a white-brownish solid (21% of the seaweed dry weight) which was used for further analysis.

Chemical characterization

FT-IR spectroscopic analysis. FT-IR spectrum was recorded on ABB MB3000 FT-IR spectrometer (Québec, QC, Canada). FT-IR spectrum was acquired over a range of 4000–650 cm^{-1} with 16 scans at a spectrum resolution of 4 cm^{-1}. Spectrum processing was carried out using the Horizon MB^{TM} FTIR software.

Total phenolic content. Phenolic content of the crude polysaccharide and commercial-grade carrageenan were determined according to the Folin-Ciocalteu method (7). A standard curve was plotted using gallic acid and the results were expressed in mg gallic acid equivalents (GAE)/ g as mean ± SD standard deviation from triplicate determination.

In vitro antioxidant activity

ABTS radical cation scavenging assay. The assay was based on the method of Re et al. (8), with minor modifications.

Reducing power assay. The assay was carried out using the method of Sellimi et al. (9), with slight modifications. In both antioxidant assays, a series of polysaccharide concentrations (1-10 mg/mL) was prepared; commercial-grade carrageenan was used as positive control. Results were expressed as mean ± SD standard deviation from triplicate determination.

RESULTS AND DISCUSSION

Chemical characterization

FT-IR spectroscopic analysis. FT-IR spectroscopic analysis is a simple, fast, accurate and non-destructive technique that requires small amounts of sample; over the last decades, it has been extensively used to identify polysaccharide structures from various seaweeds, based on the analysis of their characteristic absorbtion bands (10).

Fig. 2 presents the FT-IR spectrum of the polysaccharide isolated from *P. pseudoceranoides.* The spectrum showed characteristic bands belonging to the stretching vibration of O-H (3741–3363 cm^{-1}) (I, II) and saturated hydrocarbon groups (2958 cm^{-1}, 2891 cm^{-1}) (III, IV). The polysaccharide fraction showed a strong absorption band at 1224 cm^{-1} (V) that could be assigned to the vibration of S=O group of the sulfate ester. Besides, the spectrum had a characteristic band at 1026.05 cm^{-1} (VII) which could be assigned to the glycosidic linkage (C-O and C-C streching vibrations of the pyranose ring). The spectrum presented characteristic bands at 1068 cm^{-1} (VI) and 929 cm^{-1} (VIII) that belong to the stretching vibration of C-O group of 3,6-anhydro-D-galactose. The two strong absorption bands at 844.76 cm^{-1} (IX) and

802.33 cm^{-1} (X) could be attributed to C-O-SO_3 bond of galactose-4-sulfate and to C-O-SO_3 bond of 3,6-anhydro-D-galactose-2-sulfate, respectively (10-12).

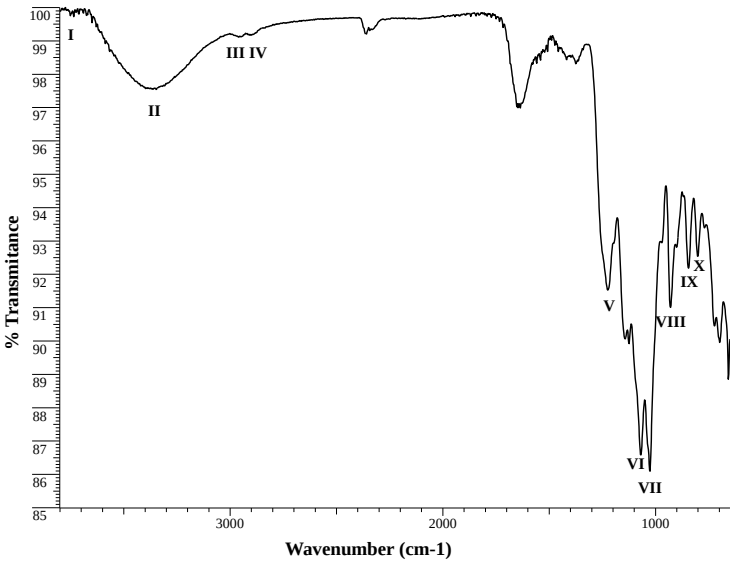

Fig. 2. FT-IR spectrum of the *P. pseudoceranoides* crude polysaccharide

The FT-IR spectrum of *P. pseudoceranoides* polysaccharide showed characteristic absorption bands of carrageenan type structure; FT-IR band assignment of carrageenans are presented in table I. Generally, the repeating disaccharide unit of carrageenans consists of alternating units of β-D-galactopyranose and α-D-galactopyranose or 3,6-anhydro-α-D-galactopyranose. As shown in table I, the FT-IR spectra of ι-carrageenan presents characteristic bands at 1210-1260 cm^{-1}, 840-850 cm^{-1} and 800-805 cm^{-1}, thus enabling us to tentatively identify the polysaccharide isolated from *P. pseudoceranoides* as ι-carrageenan (10-12).

TABLE I

FT-IR band assignment of carrageenans (adapted from Gomez-Ordonez et al. (12))

Wavenumber (cm^{-1})	Assignment	Carrageenan type

Total phenolic content. The crude polysaccharide obtained from *P. pseudoceranoides* showed a higher amount of phenolics (25.08 ± 1.00 mg GAE/g), when compared with commercial-grade carrageenan (11.17 ± 0.73 mg GAE/g). Lim et al. reported lower total phenolic content (0.039 mg GAE/g) for a fucoidan fraction isolated from *Sargassum binderi*, native to Malaysia (13).

Antioxidant activity

It has been reported that algae polysaccharides exhibit significant antioxidant effects; the antioxidant activity depends on several chemical features of polysaccharides such as molecular weight, type of major sugar units, sulfate content and solubility (3).

ABTS radical cation scavenging activity. The assay is based on the ability of antioxidants to transform the preformed radical cation ABTS, a blue-green chromophore with characteristic absorbtion at 734 nm, into its reduced form with a consequent decolorization (8). The polysaccharide and the positive control showed good ABTS radical scavenging abilities which were dose-dependent (fig. 3). The scavenging activity of *P. pseudoceranoides* polysaccharide increased from 19.00 ± 0.30% (at 0.15 mg/mL) to 49.59 ± 0.03% (at 1.5 mg/mL). However, at all tested concentrations, the positive control, commercial-grade carrageenan, was less active than the crude polysaccharide, with activities ranging from 15.68 ± 0.45% to 30.30 ± 0.03%. Shao et al. reported higher ABTS radical cation quenching abilities (36.94%) for a sulfated polysaccharide isolated from Chinese green alga *Ulva fasciata*, tested in a concentration of 0.15 mg/mL (14). Additionally, a polysaccharide isolated from *Sargassum horneri* showed higher scavenging activity (94%) at a concentration of 1.5 mg/mL (15). Several studies reported linear concentration dependent reaction kinetics for algae polysaccharides (14, 16).

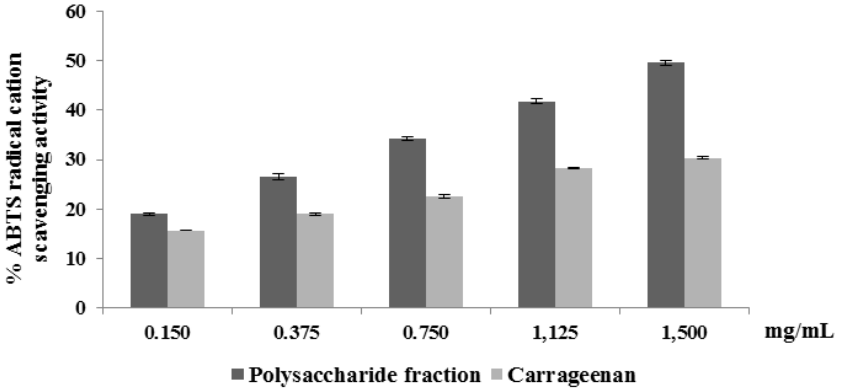

Fig. 3. ABTS radical cation scavenging effect of crude polysaccharide from *P. pseudoceranoides* and commercial-grade carrageenan

Reducing power. This method was used to evaluate the ability of the crude polysaccharide to donate an electron, thus reducing the Fe^{3+}/ferricyanide complex to the ferrous form (Perl's Prussian blue), quantified at 700 nm (17). As shown in fig. 4, the

polysaccharide reduced Fe^{3+} in a concentration-dependent manner. At 1.5 mg/mL, the crude polysaccharide exhibited higher reducing power (0.406 ± 0.002) than the positive control, commercial-grade carrageenan (0.249 ± 0.002). A liniarity of the response in the reducing power assay was observed for sodium alginate isolated from Tunisian *Cystoseira barbata;* however, according to the absorbance values at 700 nm, sodium alginate showed stronger reducing activity (the reducing power was 2 at a concentration of 1.2 mg/mL) (9).

On the contrary, a polysaccharide extracted from Chinese red alga *Porphyra haitanensis* was reported to possess lower reducing activity than the *P. pseudo ceranoides* polysaccharide; the reducing power of *P. haitanensis* polysaccharide was only 0.12 at a concentration of 1.84 mg/mL (18).

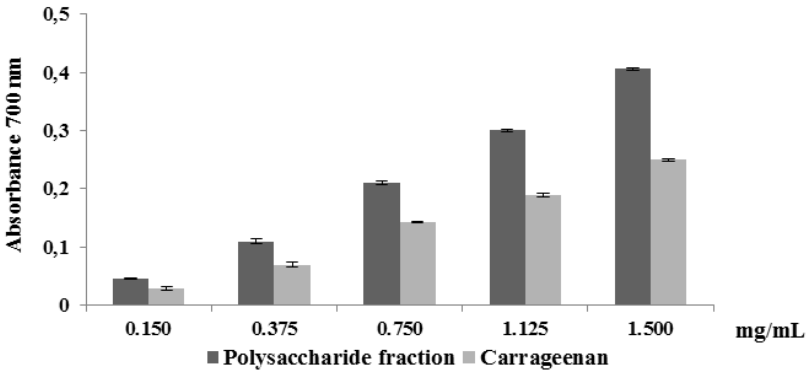

Fig. 4. Reducing power of crude polysaccharide from *P. pseudoceranoides* and commercial-grade carrageenan

CONCLUSIONS

The sulfated polysaccharide isolated from *P. pseudoceranoides* as characterized by FT-IR showed the characteristic bands of carrageenans. The crude polysaccharide, with a low phenolic content, was more active as free radical scavenger and reducing agent than the commercial-grade carrageenan. The crude polysaccharide isolated from *P. pseudoceranoides* might be used, in its present form or after purification, as an ingredient and potential antioxidant agent in the food and pharmaceutical industries.

PRELIMINARY RESEARCH CONCERNING ANTINOCICEPTIVE AND ANTI-INFLAMMATORY EFFECTS OF TWO EXTRACTS FROM *GLINUS OPPOSITIFOLIUS* (L.) AUG. DC. (Abstract): In Mali *Glinus oppositifolius* (L.) Aug. DC. (*Aizoaceae*) is used to treat inflammations and joint pains. **Aim**: The present study was designed to evaluate the antinociceptive and anti-inflammatory effects of the aqueous and ethanol extracts obtained from the aerial parts of the plant. **Material and methods:** The aqueous and ethanol extracts (G-A1 and G-E1, respectively) were studied regarding their acute toxicity. The extracts were further evaluated in different models using nociceptive (chemical, thermal, mechanical) and inflammatory stimuli. Experimental protocol was implemented according to international regulations in animal experiments. **Results and discussions:** No acute toxicity was noticed for these two extracts. ED_{50} (mg/kg bw) values were determined in different nociception models: the constrictive abdominal response test (G-A1: 229.00 ± 53.30; G-E1: 146.38 ± 31.75), hot plate test (G-A1: 278.59 ± 73.00; G-E1: 383.52 ± 89.69), Randall-Selitto test (G-A1: 207.14 ± 26.15), evaluation of the inflammatory edema test (G-A1: 228.31 ± 13.84; G-E1: 62.55 ± 89.69). **Conclusions:** The results of the inflammatory nociception studies show that G-E1 extract had a higher potency than G-A1 extract in the constrictive abdominal response test. Also, for the same level of anti-inflammatory activity, G-E1 extract was more potent than G-A1 extract. These results encourage further studies to separate, isolate and identify the phytochemicals responsible for the analgesic and anti-inflammatory effects.
Keywords: *GLINUS OPPOSITIFOLIUS* (L.) AUG. DC., ANTINOCICEPTIVE ACTIVITY, RANDALL-SELITTO TEST, INFLAMMATORY EDEMA

Since ancient times, plants have been used to treat inflammatory conditions. Willow (*Salix* sp.) is probably the best known example; its bark and leaves have been used to alleviate pain and fever. The standardized willow bark extract STW 33I (23-26% salicin) and its water soluble fraction inhibit the expression of COX-2 and TNF-α, NO release and nuclear translocation of NF-kB. Turmeric (*Curcuma longa* L.) has been used in the Traditional Chinese Medicine and Ayurvedic Medicine in the treatment of rheumatism and other inflammation-associated disorders (fever, skin and hepatic diseases). The main constituent of turmeric, curcumin, has been intensively studied as anti-inflammatory agent. Curcumin has been shown to target enzymes (COX, LOX),

cytokines (IL-1, -6, -18, TNF-α), transcription factors (NF-kB) and other mediators (NO) involved in inflammation. The resin of *Boswellia serrata* L. has many uses in the Ayurvedic Medicine among which is the treatment of rheumatic conditions. *Boswellia* resin and its ethanol extracts down-regulate the expression of COX and matrix metalloproteinases (MMP-3) and inhibit NF-kB activation. Inhibitory effects on COX, MMP, NF-kB but also a reduction of primary T-cell response have been shown for stinging nettle (*Urtica dioica* L.) extracts; in Middle Ages the plant was used to ameliorate joint pains, arthritis and gout (1, 2).

In Mali *Glinus oppositifolius* (L.) Aug. DC. (*Aizoaceae*) is used to treat inflammations and joint pains (3). The present study was designed to evaluate the antinociceptive and antiinflammatory effects of the aqueous and ethanol extracts obtained from the aerial parts of the plant.

MATERIAL AND METHODS

Plant material. The aerial parts of *Glinus oppositifolius* (L.) Aug. DC. were provided by the Department of Traditional Medicine, Bamako, Mali.

Preparation of plant extracts. The aqueous and ethanol extracts were obtained as previously described (4).

Chemicals: sodium carboxymethyl cellulose (CMC-Na) (Sigma, St. Louis, Missouri, USA), zymosan A (Sigma, St. Louis, Missouri, USA), λ-carrageenan (Sigma, St. Louis, Missouri, USA), physiological saline solution (Sicomed S.A., Bucharest, Romania).

Animals. Experiments were carried out on Swiss white male mice (20-25 g) obtained from *Cantacuzino Institute* (Bucharest, Romania). Animals were housed under constant standard laboratory conditions (room temperature 21±2°C, dark/light cycle of 12 h). The animals were fed with standard diet and water *ad libitum*. Three hours before each experiment, mice were maintained without food and water. The investigations were performed on groups of mice in the *Experimental Pharmacodynamics Laboratory*, Department of Pharmacodynamics and Clinical Pharmacy, University of Medicine and Pharmacy *Grigore T. Popa* - Iasi and followed the international regulations in animal experiments and the university specific standards (5, 6).

Antinociceptive evaluation. The study was conducted using different nociceptive (chemical, thermal, mechanical) and inflammatory stimuli.

The constrictive abdominal response. When administered intraperitoneally, zymosan A suspension produces hyper-algesia in mice. It appears a characteristic response, the constrictive abdominal response, consisting in the elongation and constriction of the animal, abdominal retraction and *opistotonus* (twisting of the trunk followed by extension of the hind limbs). The response can be reduced or abolished by administration of some analgesic drugs (7). The experiment was conducted using the method modified by Bild *et al.* (8).

The drugs were administered orally in CMC-Na suspension. The groups of mice were treated with a series of doses in geometrical progression with ratio 2. For G-A1 and G-E1 doses between 25-1600 mg/kgbw and 50-1600 mg/kg bw, respectively were used. Zymosan A suspension (20 mg/kgbw) was administered intra-peritoneally 30-90 min. after extracts administration. The number of constrictive abdominal responses was recorded for 12 min. after administration of the irritant agent (7, 9). The maximal possible effect was calculated according to the following equation:

$$\%\ Inhibition\ (Antinociception) = \frac{no.\ of\ non-responders}{no.\ of\ animals\ /group} \times 100.$$

The hot plate test. The method was described by Woolfe and Mac Donald and modified by Eddie and Laborit. The experiment was conducted using the method modified by Bild *et al.*.

Mice were placed on a hot plate (*Ugo Basile* 7280) maintained at a constant temperature of 52,5°C (*cut-off* of 30 sec.). The latency period till the first antinociceptive behavioral response was measured (10-12). The analgesic effect was evaluated using the formula:

$$\%\ \text{Inhibition (Antinociception)} = \frac{T_x - T_0}{T_m - T_0} \times 100, \text{ where:}$$

- T_x – the latency of the response measured after the administration of the extracts;
- T_0 – the latency of the response measured before the administration of the extracts;
- T_m – maximal allowed time (*cut-off* time).

Tail immersion test. The experiment was conducted using the method modified by Bild *et al.*. The animals' tails were placed in a water bath heated to 52,5°C (*cut-off* of 15 sec.) (13). The latency period till the first antinociceptive behavioral response was measured. The maximal possible effect was calculated according to the following equation:

$$\%\ Inhibition\ (Antinociception) = \frac{no.\ of\ non-responders}{no.\ of\ animals/group} \times 100.$$

Randall-Selitto test. The experiment was conducted using the method modified by Bild *et al.*. This model evaluates pain that occurs in inflammatory conditions. Inflammation was induced by subplantar injection of 1% suspension of λ-carragenan in mice. The effects of extracts on carrageenan-induced inflammation were assessed using an analgesy-meter (*Ugo Basile* 7215). This device generated a mechanical force on the affected paw (*cut-off* of 250 g). The latency period till the first antinociceptive behavioral response was measured (10, 11, 14, 15). The analgesic effect was appreciated using the formula:

$$\%\ \text{Inhibition (Antinociception)} = \frac{g_x - g_0}{g_m - g_0} \times 100, \text{ where:}$$

- g_x – the latency of the response measured after the administration of the extracts;
- g_0 – the latency of the response measured before the administration of the extracts;
- g_m – maximal allowed time (*cut-off* time).

The evaluation of the inflammatory edema. The experiment was conducted using the method modified by Bild *et al.*. The anti-inflammatory potential of the extracts was assessed by evaluating their capacity to inhibit carrageenan-induced edema (10, 11, 16, 17). The paw volume was measured using a *Ugo Bazile* 7200 plethysmometer and the inflammatory edema inhibition was appreciated using the formula:

$$\%\ Inhibition = \frac{M - T}{M} \times 100, \text{ where:}$$

- M – value of the degree of inhibition of the control group;
- T – value of the degree of inhibition of the treated group.

RESULTS AND DISCUSSION

Antinociceptive evaluation. No acute toxicity was observed in animals treated with the extracts (data not shown). This aspect allowed further investigations concerning antinociceptive /anti-inflammatory activity.

The test of the constrictive abdominal response. In case of oral administration of extracts in doses between 37.5-300 mg/kgbw (G-A1) and 50-200 mg/kgbw (G-E1), ED_{50} values of 229.00±53.30 mg/kgbw (G-A1) and 146.38±31.75 mg/kgbw (G-E1) were determined (tab. I, fig. 1-a,b). Data analysis shows that G-E1 extract had a higher potency than G-A1 extract.

The hot plate test. In case of oral administration of extracts in doses between 100-400 mg/kgbw (G-A1) and 150-600 mg/kgbw (G-E1), ED_{50} values of 278.59±73.00 mg/kgbw (G-A1) and 383.52±89.69 mg/kgbw (G-E1) were determined (tab. I, fig. 2-a,b). Data analysis shows that G-A1 extract had a higher potency than G-E1 extract.

Tail immersion test. In case of oral administration of extracts in doses between 100-400 mg/kgbw (G-A1) and 150-600 mg/kgbw (G-E1), ED_{50} values could not be identified. The maximal possible effect was 30.80% (G-A1) and 24.00% (G-E1).

Randall-Selitto test. In case of oral administration of extracts in doses between 75-300 mg/kgbw (G-A1), an ED_{50} value of 207.14±26.15 mg/kgbw was determined for G-A1 extract (tab. I, fig. 3-a,b). Using a sequence of doses between 100-400 mg/kg bw, ED_{50} value could not be determined for G-E1 extract. The maximal possible effect was 30.80%.

The evaluation of the inflammatory paw edema. In case of oral administration of extracts in doses between 75-300 mg/kgbw (G-A1) and 50-400 mg/kgbw (G-E1), ED_{50} values of 228,31 ± 13,84 mg/kgbw (G-A1) and 62,55 ± 89,69 mg/kgbw (G-E1) were determined (tab. I, fig. 4-a,b). Data analysis shows that G-E1 extract had a higher potency than G-A1 extract.

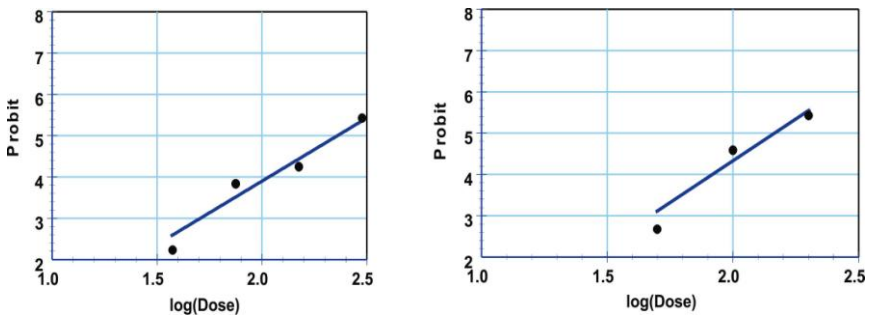

Fig. 1. The regression lines for calculation of ED_{50} of *Glinus oppositifolius* extracts in constrictive abdominal response test (**a**: G-A1, **b**: G-E1)

In case of G-A1 extract, except tail immersion test, ED_{50} values in nociception models are similar and the true confidence levels have a common overlap domain. In addition, the capacity to inhibit the inflammatory edema at 50% activity was similar with ED_{50} value for antinociceptive activity.

G-E1 extract had a different behavior in nociception models. In the tail immersion and Randall-Selitto tests, its ED_{50} values could not be determined using the established dose sequences. In the thermal stimulus nociception model, G-E1 extract was

less potent than in zymosan nociception model. The inhibitory activity on inflammatory edema at 50% activity was achieved at 62.55 ± 89.69 mg/kgbw (tab. I).

The analysis of inflammatory nociception models shows that G-E1 extract had a higher potency than G-A1 extract in the constrictive abdominal response test. Also, for the same level of anti-inflammatory activity, G-E1 extract was more potent than G-A1 extract.

CONCLUSIONS

G-A1 extract showed antinociceptive activity in all tested nociception models except tail immersion test. Additionally, it had anti-inflammatory activity. Taking into consideration the ED_{50} values and the ability of the phytocomplex to inhibit the release of mediators of inflammation and pain by applying appropriate stimuli, it can be concluded that both activities are equally present. The extract has the characteristic profile of moderate analgesics and NSAIDs.

G-E1 extract showed a good anti-inflammatory activity. The extract has the characteristic profile of NSAIDs. In nociception models using thermal stimuli, the extract had a low potency and, in some situations, ED_{50} could not be determined. G-E1 extract has the ability to inhibit the inflammatory mediators release. The extract showed a high potency in inflammatory paw edema test (ED_{50}=62.55±89.69 mg/kg bw) and constrictive abdominal response test (ED_{50}=146.38±31.75 mg/kg bw).

The results in nociception models using thermal stimulus (working temperature of 52.5°C) invalidate the morphine-like behavior of the extracts. However, such a behavior cannot be excluded but in case it would be present, it is certainly moderate, similar to that of codeine.

These data confirm the validity of the working hypotheses and encourage further studies concerning the separation, isolation

and identification of groups of active phytochemicals with analgesic and anti-inflammatory effects.

ACKNOWLEDGEMENTS

Alexandru Vasincu acknowledges AM-POSDRU for financial support of the research in the project "Interuniversity partnership for increasing the medical doctoral research quality and interdisciplinarity through doctoral scholarships–DocMed.net" (POSDRU/107/1.5/S/78702). TAGUCHI METHOD FOR PARTIAL DIFFERENTIAL EQUATIONS WITH APPLICATION IN TUMOR GROWTH (Abstract): The growth of tumors is a highly complex process. To describe this process, mathematical models are needed. A variety of partial differential mathematical models for tumor growth have been developed and studied. Most of those models are based on the reaction–diffusion equations and mass conservation law. A variety of modeling strategies have been developed, each focusing on tumor growth. **Material and methods**: Systems of time-dependent partial differential equations occur in many branches of applied mathematics. The vast majority of mathematical models in tumor growth are formulated in terms of partial differential equations. We propose a mathematical model for the interactions between these three cancer cell populations. The Taguchi methods are widely used by quality engineering scientists to compare the effects of multiple variables, together with their interactions, with a simple and manageable experimental design. In Taguchi's design of experiments, variation is more interesting to study than the average. **Results:** First, Taguchi methods are utilized to search for the significant factors and the optimal level combination of parameters. Except the three parameters levels, other factors levels other factors levels would not be considered. Second, cutting parameters namely, cutting speed, depth of cut, and feed rate are designed using the Taguchi method. Finally, the adequacy of the developed mathematical model is proved by ANOVA. According to the results of ANOVA, since the percentage contribution of the combined error is as small. **Conclusions:** Many mathematical models can be quantitatively characterized by partial differential equations. The use of MATLAB and Taguchi method in this article illustrates the important role of informatics in research in mathematical modeling. The study of tumor growth cells is an exciting and important topic in cancer research and will profit considerably from theoretical input. Interpret these results to be a permanent collaboration between math's and medical oncologists. **Keywords:** TUMOR GROWTH, DIFFERENTIAL EQUATIONS, TAGUCHI METHOD, NUMERICAL MODELING

Cancer is a generic name given to a group of malignant cells that have lost their specialization and normal control growth. This group of malignant cells can be regarded as a nonlinear dynamic system self-organized in time and space. Mathematical modeling is a process by which a real world problem is described by a mathematical formulation. Mathematical modeling of avascular tumors can be seen as the first step in building models for tumors in later stages (1, 2). Taguchi methods consist of 3

phases: designing the experiment, running and analyzing, and confirming and validating the assumptions (3, 4).

MATERIAL AND METHODS

The model is based on a set of partial differential equations with form:

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{\partial}{\partial x}[\frac{u}{u+v}\frac{\partial}{\partial x}(u+v)] + g(c)u(1-u-v) - f(c)u. \\ \frac{\partial v}{\partial t} = \frac{\partial}{\partial x}[\frac{v}{u+v}\frac{\partial}{\partial x}(u+v)] + f(c)u - h(c)v \\ \frac{\partial w}{\partial t} = h(c)v \\ c = \frac{c_1[1-\alpha(u+v+w)]}{\beta+u}, \beta = \frac{k_1}{k_2} \end{cases}$$

Where are denoted by:

$u(x,t), b(x,t), v(x,t), w(x,t)$ the cell densities for the proliferating, quiescent, necrotic cells and concentration of some nutrients (1),(2). In this stage, Taguchi methods were used to find the optimal parameters combination. Taguchi (4) has envisaged a new method of conducting the design of experiments which are based on well defined guidelines. This method uses a special set of arrays called orthogonal arrays. These standard arrays stipulate the way of conducting the minimal number of experiments which could give the full information of all the factors that affect the performance parameter. The table I shows an L^{16} orthogonal array (3). There are totally 16 experiments to be conducted and each experiment is based on the combination of level values as shown in the table. The third experiment is conducted by keeping the independent design variable 1 at level 1, variable 2 at level 3, and variable 3 at level 3.

TABLE I

Layout of L^{16} orthogonal array.

Taguchi's orthogonal arrays are highly fractional orthogonal designs

Exp. No.	Parameter 1	Parameter 2	Parameter 3
1	1	1	1
2	1	2	2
3	1	3	3
4	1	4	4
5	2	1	2
6	2	2	1
7	2	3	4
8	2	4	3
9	3	1	3
10	3	2	4
11	3	3	1
12	3	4	2
13	4	1	4
14	4	2	3
15	4	3	2
16	4	4	1

The relationship between one column and another is arranged so that factor for each level within one column, each level within any other column occur an equal number of times as well. These designs can be used to estimate main effects using only a few experimental runs.

There are totally 16 experiments to be conducted and each experiment is based on the combination of level values as shown in the table II. The third experiment is conducted by keeping the independent design variable 1 at level 1, variable 2 at level 3, and variable 3 at level 3.The additive assumption implies that the individual or main effects of the independent variables on performance parameter are separable, but the model assumes that there exist no cross product interactions among the individual factors (4). Furthermore, each factor can be assigned a significance weight to denote its importance in affecting the end result of the experiment.

RESULTS

The design of the experiments has an effect on the number of experiments required. Taguchi's experimental approach was applied to design the experiments using the three parameters of this study .The results of the 16 experiments of Taguchi's L^{16} series, were analyzed in order to determine the mean effect of each factor. These results suggest that the method of Taguchi's optimization approach remarkable rapid tumor growth. A major finding of the study was that the Taguchi methods predicted the combination of factors that results in the lowest survival of the malignant cells. The experimental results indicate that the proposed mathematical models suggested could adequately describe the performance indicators within the limits of the factors that are being investigated. After the simulation model using different values of the three parameters α,k_1 and k_2 are obtained following fig. 1.

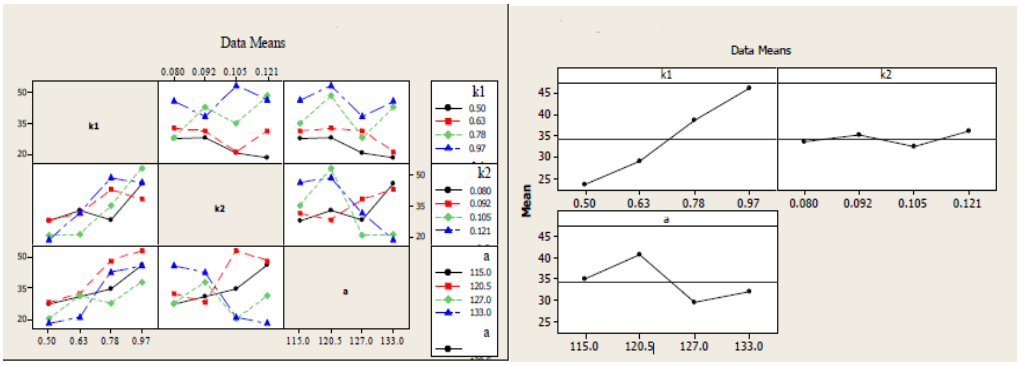

Fig. 1. The results of L^{16}.

Each experiment run was done in triplicate and repeated three times, the mean values were calculated and the results were expressed as mean. The adequacy of the predictive model was verified using ANOVA at 95% confidence level. The ANOVA revealed that feed is the most significant factor influencing the response variables investigated. The first step in the optimization process is to determine the ratio for the entire experiments test. The percentage contribution of each control factor is employed to measure the corresponding effect on the quality characteristic. In this experiment, Taguchi's graphical approach is used to plot the "marginal means" of each level of each factor and "pick the winner" to determine the best setting for each control factor. An advantage of the Taguchi method is that it emphasizes a mean performance characteristic value close to the target value rather than a value within certain specification limits.

CONCLUSIONS

In this paper we presented a partial differential equations model of avascular tumor growth which consists of proliferating, quiescent and necrotic cells and includes chemo taxis interactions and nutrient diffusion. The use of Taguchi method in this article illustrates the important role of informatics in research in mathematical modeling. A major finding of the study was that the Taguchi methods predicted the combination of factors that results in the lowest survival of the malignant cells. We have presented this method in systems of partial differential equations, which is integration based. For model systems have been chosen to demonstrate the validity of this method. We have seen that this method is relatively simple and therefore requires very little computational time. The study of avascular tumor growth cells is an exciting and important topic in cancer research and will profit considerably from theoretical input.

SPECTROMETRIC METHOD FOR THE ASSAY OF RAMIPRIL USING MOLYBDOPHOSPHORIC ACID (Abstract): Ramipril is a drug of the angiotensin converting enzyme inhibitor class. **Aim:** A new molecular absorbance spectrometric method was developed for the assay of ramipril using molybdophosphoric acid in acidic medium. **Material and methods:** The reaction product showed a maximum absorbance at 361 nm. The optimum conditions of the reaction were established. The developed method was validated. **Results:** The method showed a good linearity in the range of 8 - 36 μg/ml (correlation coefficient r = 0.9996). The detection limit (LD) was 0.86 μg/ml and the quantification limit (LQ) 2.88 μg/ml. Precision and accuracy were determined (RSD = 1.15%); mean recovery was 98.90% in the 97.13-101.03% concentration range. **Conclusions:** The proposed method is simple, easy to perform, sensitive, linear, precise, accurate and robust. **Keywords:** RAMIPRIL, MOLYBDOPHOSPHORIC ACID, SPECTROMETRIC METHOD, VALIDATION.

Ramipril is a drug of the angiotensin converting enzyme (ACE) inhibitor class that is primarily used in the treatment of high blood pressure and congestive heart failure. Ramipril, a prodrug, is converted to the active metabolite ramiprilat by liver esterase enzymes. Ramiprilat is mostly excreted by the kidneys. The half-life of ramiprilat is variable (3–16 hours), and is prolonged by heart and liver failure, as well as kidney failure (1).

This paper presents a UV-Vis molecular absorbance spectrometric method for the assay of ramipril using molybdophosphoric acid in acidic medium. When comparing it to other assay methods in the literature, the proposed method is simple, easy to perform, sensitive, linear, precise, accurate and robust (2-3). The developed method was validated using the following criteria: linearity, detection and quantification limit, precision, accuracy and robustness (4-7).

MATERIAL AND METHODS

Reagents and apparatus:

- ramipril (99.21% reference substance, produced by Lupin, India);
- 0.1 M - 1.0 M hydrochloric acid aqueous solutions;
- 0.1% - 3.0% molybdophosphoric acid aqueous solutions;
- 0.01% sodium lauryl sulphate aqueous solution;
- analytical balance (Kern 770);

- UV-Vis Spectrophotometer (Hewlett Packard 8453).

Except ramipril, all other reagents were produced by Merck, Germany.

Principle of the method: Ramipril forms with molybdophosphoric acid in hydrochloric acid medium an insoluble compound which can be spectrometrically measured at 361 nm.

In order to establish the optimum wavelength for the detection, 2 ml of the 10 µg/ml working solution were mixed with 1 ml 0.2 M hydrochloric acid and 1% molybdophosphoric acid solution; then, 1 ml 0.01% sodium lauryl sulphate was added in order to prevent precipitation. The UV-Vis absorption spectrum was recorded using 1 cm cell, after 20 minutes.

In order to establish the optimum working conditions, two solutions of 8 µg/ml and 32 µg/ml were used, while the parameters of the method were changed. The optimum concentration of the hydrochloric acid solution and molybdophosphoric acid solution was established and the stability of the reaction product was evaluated.

Procedure: 1 ml 1M hydrochloric acid and 1 ml of 2% molybdophosphoric acid solution were added to 1 ml ramipril solution and 1 ml of 0.02% lauril sodium sulphate. The absorbance was measured at 361 nm versus a blank solution prepared in identical conditions.

RESULTS AND DISCUSSION

The analysis of absorption spectra showed a maximum absorbance for the reaction product at 361 nm. This value was used for all the determinations (fig. 1).

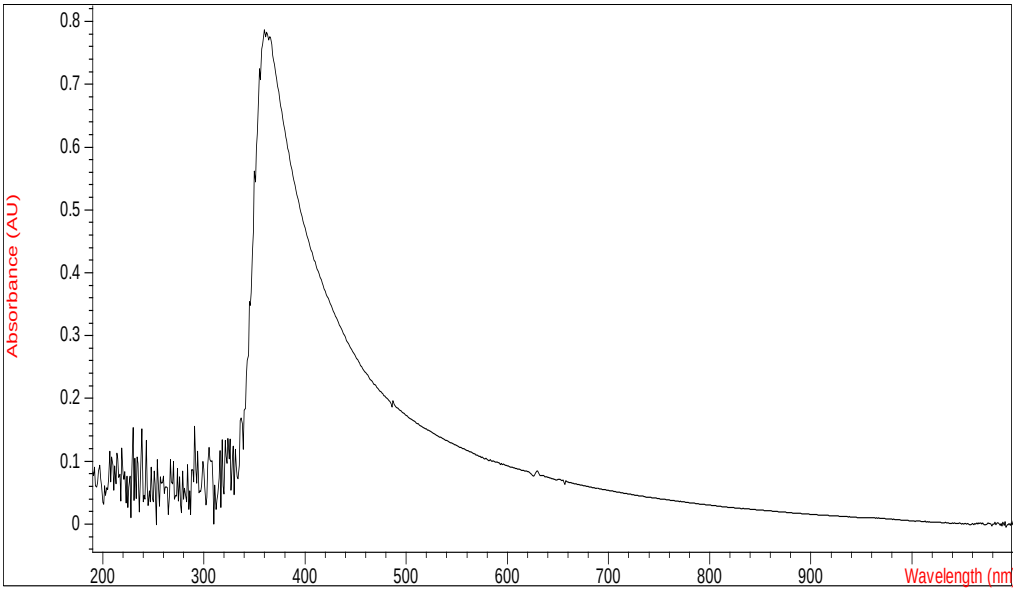

Fig. 1. Spectrum of the reaction product obtained for 32 µg/ml ramipril

The best concentration of the hydrochloric acid was established at 1 M, because when using that solution the maximum absorbance measured at 361 nm had the greatest value (tab. I). The same criterion was used when optimum concentration

of molybdophosphoric acid was set to 1% (tab. II). By studying the stability of the samples it was established that the chemical reaction between ramipril and molybdophosphoric acid was complete 20 minutes after the last reagent was added. The results proved that absorbance remained almost the same for at least another 20 minutes, sufficient time for the measurements to be performed (tab. III).

40	0.89181	0.89302	0.92068	0.90763	0.90329
Correlation and regression coefficients r = 0.9996, r^2 = 0.9992; Standard error = 0.0079; Intercept = – 0.0951; Slope = 0.0277					

Linearity was studied in the 4-40 µg/ml concentration range (fig. 2). The obtained data were statistically evaluated (tab. IV) and the calibration curve was obtained (fig. 3).

According to the experimental data, the developed method for ramipril determination was linear in the concentration range of 8 – 36 µg/ml.

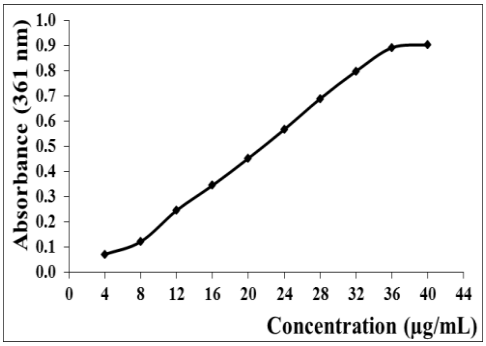

Fig. 2. Method linearity

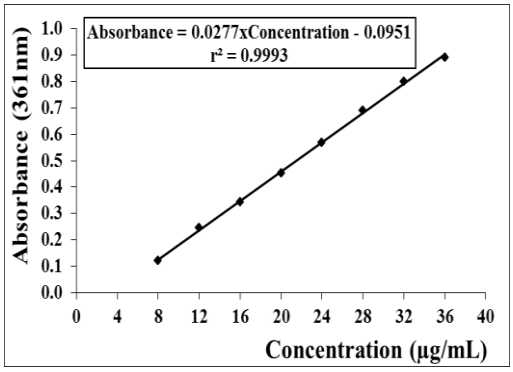

Fig. 3. Calibration curve

Detection and quantification limits were calculated using the following formulas (4-7):

LD = 3 x Standard error / Slope = 0.86 µg/ml

LQ = 10 x Standard error / Slope = 2.88 µg/ml

When we compared this concentration range with that of other published methods we found out that this new method has the following advantages: it does not involve rare or complex reagents, nor does it involve the use of toxic solvents. It is simple and easy to perform (2, 3). The calibration curve equation was established (fig. 3).

For precision determination, three solutions of 16, 20 and 24 µg/ml ramipril were used. Three assays were performed for each concentration. Two sets of assays were performed in different days in order to evaluate the intermediate precision.

Samples concentrations were calculated using the calibration curve equation (tab. V). We found that for each set of data and for both sets together the relative standard deviation was lower than 2%. This fact proved that the proposed method was precise.

In order to establish the accuracy of the method, ramipril solutions of 16, 20, and 24 µg/ml were analyzed. For each concentration, three determinations were performed (6).

The concentration of the samples was calculated based on the experimental absorbance values, using the regression curve equation (tab. V). We found that recovery was 100.59% for the studied concentration range, mean 98.90% (minimum 98.51% and maximum 102.39%), and the relative standard deviation was under 2% (RSD = 1.42 %). These values prove that the proposed method was accurate.

A robustness study was performed to establish system suitability in order to ensure the validity of the analytical procedure. This was done by varying the instrument, analyst, and time of study. The analysis was performed on Shimadzu UV-Visible spectrophotometer, model-1700. Interday and intraday analysis was performed by changing the analyst. Reproducibility of the results confirmed the robustness of the method.

TABLE V

Precision and accuracy of the method

Concentration (µg/ml)	Precision		Intermediate precision		Accuracy	
	Real concentration (µg/ml)	RSD %	Real concentration (µg/ml)	RSD %	Real concentration (µg/ml)	Recovery (%)

					Mean	98.90

CONCLUSIONS

A UV-VIS molecular absorbance spectrophotometric method was developed for the assay of ramipril using molybdophosphoric acid in hydrochloric acid medium. The reaction product showed a maximum absorbance at 361 nm.

The analytical method was validated for the linearity range of 8.0 - 36 µg/ml, with a correlation coefficient of r = 0.9996, detection limit of 0.86 µg/ml, quantification limit of 2.88 µg/ml below the lowest concentration of the linearity range, method precision RSD% = 0.35% (4), and accuracy evaluated by recovery R = 98.90%.

In conclusion, the proposed method is simple, easy to perform, sensitive, linear, precise, accurate and robust.

PHYTOTOXICITY ASSESSMENT OF METHANOLIC EXTRACTS FROM *CORIADRUM SATIVUM* L. FRUITS (Abstract): The fruits of *Coriandrum sativum* L. (Apiaceae) are used as a spicing and flavoring agent in food products and are also recommended as a drug in the treatment of digestive tract disorders. The safety of botanicals and botanical preparations used as food supplements is of great interest, as the market of such products is expanding worldwide. **Aim:** In this study, aimed at assessing the safety of coriander as food ingredient, we investigated the phytotoxicity of fruit extracts on *Triticum aestivum* L. **Material and methods:** We studied the effects of methanolic coriander fruit extracts, Omagiu cultivar (V1-V3; three dilutions: 1%, 2.5% and 5 % in distilled water), upon germination, elongation, and accumulation of fresh and dry biomass in the plants; also it was investigated the influence of the extracts on mythosis in root tissues. **Results and discussions:** The extracts did not influence the germination and growth of test plants and did not inhibit root and shoot elongation of wheat plants (a 20 % increase in root length over the control being registered for V2 1%). Frequency of aberrant anaphases and telophases in *Triticum aestivum* L. varied slightly around the percentage of the control, the highest percent of aberrant chromosomes (5.07 %) being observed in V3 2.5 %. **Conclusions:** The investigated coriander fruit extracts did not have phytotoxic effects but had a slight stimulating effect on germination and growth of *Triticum aestivum* L. **Key words:** *CORIANDRUM SATIVUM* L., *TRITICUM AESTIVUM* L., PHYTOTOXICITY, CYTOGENETIC EFFECT.

The study of synthetical or natural drugs toxicity is essential in order to assess their pharmaceutical use and the risks for consumer exposure to these products. The safety of botanicals used as food supplements is of great interest, as the market of such products is expanding worldwide. For this reason, in 2009, the Scientific Committee of the European Food Safety Authority (EFSA) adopted a series of regulations regarding the safety assessment of botanicals and botanical preparations widely used as food supplements (1) even though in the past these products were believed side effect-free.

The fruits of *Coriandrum sativum* L. (Apiaceae) are used as spicing and flavoring agents in food products, liqueurs, and tobacco. As well, they are recommended in the treatment of digestive tract disorders due to their digestive, anti-foaming, and spasmolytic properties (2).

Coriander fruits have a long history of use as a spice and in phytotherapy with no record of notable adverse effects(3); by this token, we used an *in vivo* phytotoxicity test for assessing the risks associated with the use of coriander fruits, Omagiu cultivar. We studied the cyto- and genotoxicity of coriander extracts upon *Triticum aestivum* L.(wheat) as test species.

MATERIAL AND METHODS

Coriander fruits, Omagiu cultivar, were harvested during August 2011 from plants cultivated in the fields of the Secuieni Agricultural Research and Development Center (Neamt County, Romania) under the same soil and climatic conditions, the differences being some agrotechnical factors such as the nutritional space; the three experimental samples were named V1, V2 and V3.

The phytobiological studies were carried out using grains of *Triticum aestivum* L., Dor variety (4). We studied the effects of methanolic fruit extracts upon germination, elongation and accumulation of fresh and dry biomass in the plants; we have also investigated the influence of extracts on mythosis in root tissues.

The methanolic extracts were obtained from delipidated coriander fruits with a drug:extract ratio of 2.5:100 g/mL. Total phenolic compounds in the methanolic coriander fruit extracts were determined as gallic acid equivalents by Folin-Ciocalteu method (5).

The experiment consisted in three treatments per sample by diluting the initial methanolic extract with distilled water (1%, 2.5% and 5%) and one control (distilled water) (tab. I). Both for the control and for each dilution we used groups of 200 wheat grains.

*Study on the effect of coriander seeds extracts on wheat plants germination, root and shoot elongation. S*eeds of test plants were soaked for 24 hours in 50 ml of each treatment variant and in the same volume of distilled water for the control. After that, 150 wheat seeds were washed and placed uniformly upon a system made of sieves, with plastic vessels filled with water placed below (6). Cultivation was done in an air-conditioned chamber, at an average air temperature of 22±2 ºC and constant light of 2500 lux. After 7 days, germination was abstained, seed germination rate was calculated and shoot and root length was measured. Seedlings having less than 50 mm in length (both root and stem) were excluded from the experiment.

Study on the effect of coriander seeds extracts on fresh and dry biomass accumulation in Triticum plants. After 7 days, fresh weight (Wf) of roots and shoots for each treatment variant was determined. Their dry weight (Wd) was measured after oven drying at 60ºC for 24 hours.

Biological effects were evaluated by using the equation: Wd/Wf x100.

Study on the effect of coriander seed extracts upon mythosis in root meristems

The remaining 50 pre-imbibed grains were placed in 10 cm diameter Petri dishes, on filter paper moistened with distilled water. After 72 hours, the primary roots were cut off and a squash preparation stained with Schiff reagent was obtained (7). Both normal ana- and telophases and those with different types of aberrations (bridges, fragments, fragments and bridges, tri- and tetrapolar anaphases, chromosomes in ring) were counted.

RESULTS AND DISCUSSION

The amount of total phenolic com-

pounds in coriander fruit methanolic extracts of were determined as gallic acid equivalents (g GAE %) (tab. I); as shown, the differences between the investigated coriander samples are not significant.

Seed germination of *Triticum aestivum* was used to ascertain the effect of methanolic extracts of coriander fruits, Omagiu cultivar, on physiological process during initial seedling growth. Germination rate and the percentage of seedlings less than 50 mm in length are shown in table II.

TABLE I

Total phenolic compounds in methanolic extracts of Omagiu coriander fruits

Sample	g GAE %
V1	0.13 ± 0.00
V2	0.13 ± 0.00
V3	0.14 ± 0.00

TABLE II

The effect of coriander bioactive compounds on wheat plants germination

Treatment variant	Concentration (%)	Germination rate (%)	Seedlings (%) < 50 mm
Control		**97.97**	**0**
V1	1	97.87	0
	2.5	99.33	2.01
	5	98.01	3.31
V2	1	96.73	0
	2.5	97.24	0
	5	98.01	2.65
V3	1	96.58	0
	2.5	97.97	2.70
	5	95.36	3.97

At the used concentrations the differences in germination rate between the tested treatments were insignificant and similar with those of the control (fig. 1).

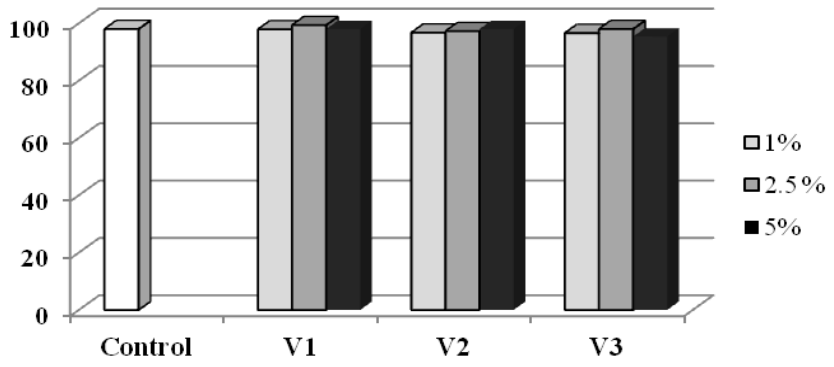

Fig. 1. Germination rate of wheat seeds on coriander fruit extracts treatment

Also, when the percentage of undeveloped seedlings (smaller than 50 mm) was analyzed, we concluded that of a total of nine treatment variants four caused normal growth while the plants treated with the remaining five variants were relative small.

The influence of the treatment with coriander fruit extracts on the growth of *Triticum aestivum* plants (fig. 2) was established by measuring the lengths of roots and shoots and also by determining the fresh and dry weight of seedlings (tab. III).

Fig. 2. *Triticum aestivum* L. seedlings at the end of the experiment

TABLE III

Effect of coriander extracts on root and shoot length and fresh and dry matter accumulation in *Triticum aestivum* L.

Treatment variant	Conc. (%)	Root length (mm)±SD	Shoot length (mm)±SD	Root weight (g)		Water content (%)	Shoot weight (g)		Water content (%)
				fresh	dry		fresh	dry	
Control		**137.37±19.24**	**115.46±17.78**	**6.55**	**0.85**	**87.02**	**9.54**	**1.40**	**85.33**
V1	1	165.39±35.13	117.33±18.06	6.10	0.90	85.25	9.44	1.43	84.85
	2.5	154.50±18.52	121.50±16.91	7.68	0.88	88.54	9.95	1.44	85.53
	5	146.41±20.36	120.54±13.73	6.36	0.86	86.48	9.67	1.43	85.21
V2	1	168.74±28.32	126.69±22.56	7.43	0.92	87.62	10.62	1.58	85.12
	2.5	158.75±19.39	121.63±16.41	6.01	0.81	86.52	10.13	1.50	85.19
	5	146.88±17.87	115.53±20.06	6.07	0.83	86.33	9.20	1.33	85.54
V3	1	148.15±15.61	117.48±23.48	6.80	0.89	86.91	9.92	1.44	85.48
	2.5	154.98±21.56	124.75±14.34	6.76	0.83	87.72	9.80	1.43	85.41
	5	140.57±19.56	118.75±21.38	6.66	0.82	87.69	9.55	1.42	85.13

As shown in the table, coriander extracts had a slight stimulating effect upon root and shoot elongation of wheat plants; at a concentration of 5%, V3 determined the lowest increase (2.33 %) in root length over the control, while V2 1% exhibited the highest increase (20 %). Likewise, shoot elongation was stimulated, the lowest value being calculated for V1 1% and the highest for V2 1% (9.73 %).

The weight of fresh and dry roots and shoots are important parameters in the assessment of coriander extracts phytotoxicity, as the water content of these vegetative organs can be the result of increased/decreased tissue turgescence.

Four treatment variants (V2 2.5%, V2 5%, V3 2.5% and V3 5%) of the nine investigated variants had a detrimental effect on dry weight accumulation in roots (with a 2.35-4.71% decrease over the control) induced by the inhibitory action of the extracts upon the meristems growth and an increase in its water content. Contrary, the remaining 5 treatment variants (V1 1%, V1 5%, V2 2.5%, V2 5% and V3 1%) enhanced root growth, as revealed by the increase in dry weight and low water content, in comparison with the control.

Coriander extracts exhibited a stimulating effect on dry weight accumulation in shoots, their turgescence being close to that of the control.

It remains to be seen if the increase in tissue weight is induced through stimulation of plant growth or by a higher amount of bioactive compounds synthesized by the test plants (tab. IV).

TABLE IV

Frequency of aberrant anaphases and telophases in *Triticum aestivum* L. on coriander extracts treatment

Treatment variant	Concentration (%)	Number of analyzed anaphases and telophases	Aberrant anaphases and telophases	
			Number	%
Control		**894**	**33**	**3.35 ± 0.01**
V1	1	1231	56	4.53 ± 0.02
	2.5	1196	36	3.01 ± 0.01
	5	1056	36	3.41 ± 0.01
V2	1	1470	45	3.06 ± 0.01
	2.5	829	32	3.86 ± 0.02
	5	1121	47	4.19 ± 0.03
V3	1	820	29	3.54 ± 0.01
	2.5	945	48	5.07 ± 0.01
	5	780	36	4.61 ± 0.02

Cytogenetic analysis showed the presence of chromosomal aberrations with a frequency of 3.35 % in the control, considered to be normal with *in vivo* phytotoxicity testing. Consequently, a certain genotoxicity induced by coriander extracts should be considered when the prevalence of chromosomal aberrations is higher than 6 %. The graphic representation of aberrant anaphase and telophase frequency in the analyzed samples (fig. 3) revealed the lack of mutagenic effect of coriander fruit extracts.

The highest percent of aberrant chromosomes (5.07 %) was observed for V3 2.5 % treatment; this value is below the accepted frequency of 6 %.

Using anaphase analysis, we established anaphase and telophase bridges, as well as chromosome fragments (fig. 4).

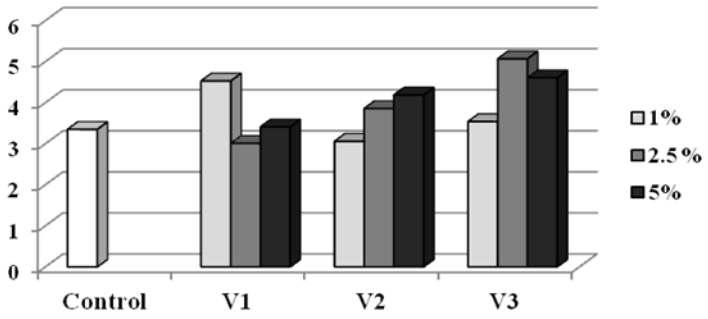

Fig. 3. Frequency of coriander extracts-induced chromosomal aberrations in *Triticum aestivum* root meristem

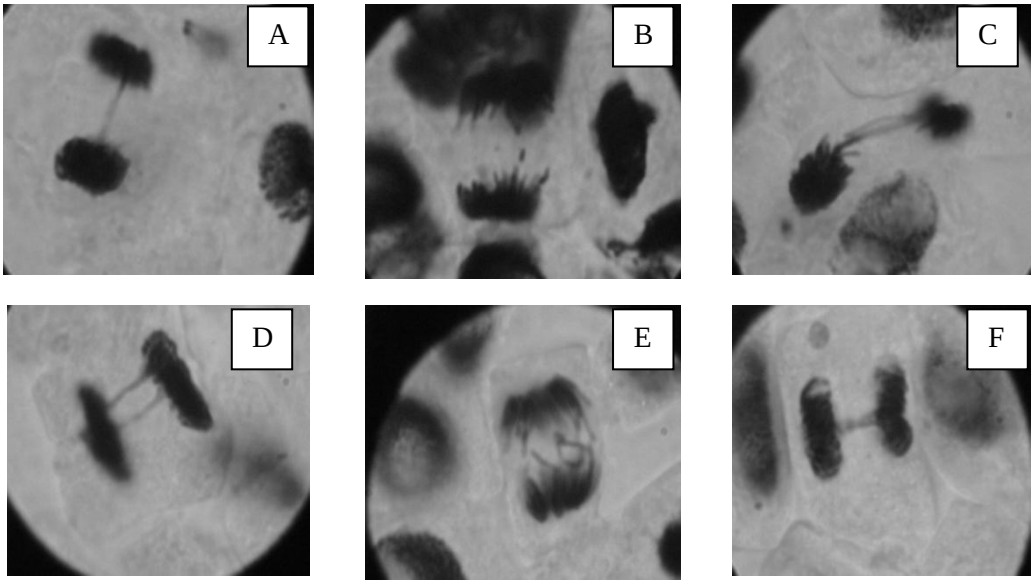

Fig. 4. Photomicrographs of coriander extracts effects on mitotic activity in wheat root meristems cells (A- ana-telophase bridge; B- anaphase with chromosome fragments; C- anaphase bridge; D- telophase with multiple bridges, E- anaphase with a vagrant chromosome; F-telophase bridges and micronuclei).

CONCLUSIONS

In summary, we tested the phytotoxicity of coriander fruit extracts, Omagiu cultivar. The present study showed, as we expected, no significant influence upon the germination and growth of *Triticum aestivum* plants. Likewise, the investigated extracts and their constituents did not inhibit root and shoot elongation of wheat plants (a 20 % increase in root length over the control being recorded for V2 1%).

Frequency of aberrant anaphases and telophases in *Triticum aestivum* L. varied slightly around the percentage of the con-

trol; the highest percentage of aberrant chromosomes (5.07 %) was observed for V3 2.5 % treatment.

The general conclusion is that the investigated coriander fruit extracts do not possess phytotoxic effects and have a slight stimulating effect on *Triticum aestivum* L. germination and growth.

UTILIZAREA TEHNOLOGIILOR DE TIP CAD/CAM ŞI DE FABRICARE RAPIDĂ ÎN PRODUCEREA PROTEZELOR ŞI ORTEZELOR

O. Ciobanu
Universitatea de Medicină şi Farmacie „Grigore T. Popa" Iaşi
Facultatea de Bioinginerie Medicală
Departamentul de Ştiinţe biomedicale

THE USE OF CAD/CAM AND RAPID FABRICATION TECHNOLOGIES IN PROSTHESIS AND ORTHOTICS MANUFACTURING (Abstract): Modern CAD/CAM and rapid fabrication technologies used in the prosthesis and orthotics manufacturing are based on 3D scanning, 3D reconstruction and computer aided fabrication. **Aim:** Paper approaches a study on the manufacture of customised orthosis (foot insole) through CAD/CAM and rapid fabrication technologies, using most economical devices and software available in Romania. **Material and methods**: Paper describes a method used in the data acquisition, reconstruction and fabrication of a foot insole made of acrylonitrile butadiene styrene (ABS). Data acquisition is accomplished using non contact 3D scanner with structured light. Structured-light 3D scanner is a device for scanning the three dimensional shape of an anatomical surface using projected light patterns and a camera system. All working steps from 3D scanning to computer aided fabrication of the foot insole through rapid ptototyping are described. Peculiar attention has been given to the image processing steps from 3D reconstruction to the final 3D CAD modelling of the foot insole. **Results**: The approached method showed a good accuracy in scanning of anatomic surfaces and in speeding up fabrication of leg orthosis. The 3D printer was able to build durable ABS thermoplastic insoles without post treatment. **Conclusions**: Approached fabrication method showed the advantages of manufacturing of orthosis and prosthesis components through CAD/CAM and Rapid Fabrication technologies. New prosthetic laboratories may be equipped with Rapid Fabrication technologies like 3D scanners and 3D printers. **Key words**: PROSTHESIS, FOOT INSOLE, CAD/CAM, RAPID MANUFACTURING

Dezvoltarea continuă a pieţei dispozitivelor de protezare şi de ortezare a determinat înfiinţarea unor societăţi naţionale de profil, care împreună cu Ministerul Sănătăţii, Casa Naţională de Asigurări de Sănătate şi medicii specialişti au dezvoltat programe naţionale de sănătate cu scopul de a susţine, cel puţin parţial, costurile procedurilor de protezare.

Casa Naţională de Asigurări de Sănătate a încheiat anual contracte cu furnizorii de dispozitive medicale, numărul acestora fiind de exemplu, de 2.922 în anul 2009, în creştere faţă de anii anteriori. În anul 2009, Casa Naţională de Asigurări de Sănătate a făcut plăţi în valoare de 95.218 mii lei pentru dispozitive şi echipamente medicale (1).

În acest context apare necesitatea studierii şi implementării unor metode moderne şi eficiente de fabricare bazate pe tehnologiile de tip CAD/CAM şi de fabricare rapidă care să vină în întâmpinarea atât a cere-

rilor de dispozitive de protezare, ortezare sau de tehnologie asistivă cât şi a cererilor de reparaţii sau de fabricare a pieselor de schimb.

Tehnologiile de tip CAD/CAM se referă la sisteme de scanare şi măsurare a suprafeţelor anatomice sau a obiectelor şi la maşini unelte de prelucrat orice tip de material, dotate cu echipamente numerice şi cu comandă prin calculator. Prin tehnologiile de tip CAD/CAM se pot fabrica în serie mică sau în serie mare, componente din orice material, dar cu o pregătire a fabricaţiei mai lentă şi un preţ de cost mai ridicat.

Tehnologiile de fabricare rapidă (sau de prototipare rapidă) se referă la maşini de prelucrat (de regulă pentru materiale plastice) numite în unele cazuri şi imprimante 3D comandate printr-un calculator. Tehnologiile de fabricare rapidă pot fabrica rapid diverse componente personalizate (unicate) mai ales din materiale plastice, la un preţ scăzut.

În această lucrare s-a efectuat un studiu în vederea realizării unei orteze de picior personalizate cu aplicarea tehnologiilor de tip CAD/CAM şi de fabricare rapidă, de preţ moderat, disponibile în România. Prin modelul de orteză (talonetă) personalizată studiată în această lucrare se permite parcurgerea detaliată a tuturor etapelor de lucru, de la scanarea pacientului cu un scaner 3D până la producerea fizică a ortezei. Tehnologiile de tip CAD/CAM şi de fabricare rapidă acoperă fabricarea unei game foarte largi de componente de proteze şi orteze, de dispozitive şi aparate de tehnologie asistivă, de componente de echipamente de fitness, aparate tehnico-medicale, etc.

MATERIAL ŞI METODE

Metodele moderne de fabricare a ortezelor şi a protezelor se bazează pe utilizarea intensivă a tehnologiilor de tip CAD/CAM şi de prototipare rapidă. Dintre tehnologiile moderne de tip CAD/CAM se remarcă: scanarea 3D, reconstrucţia 3D şi fabricarea componentelor protezelor şi ale ortezelor cu mijloace de tip CAD/CAM sau cu imprimante 3D.

Pentru protezele personalizate se întâlnesc în general, următoarele metode principale de fabricare (2,3), considerând cazul protezării unui membru:

- Fabricarea manuală, cu fazele de lucru prezentate în fig.1;
- Fabricarea cu mijloace CAD/CAM, cu fazele de lucru prezentate în fig.2;
- Fabricarea cu mijloace de fabricare rapidă (sau prototipare rapidă), cu fazele de lucru prezentate în fig.3.

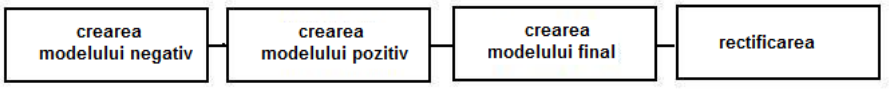

Fig. 1. Fabricarea manuală

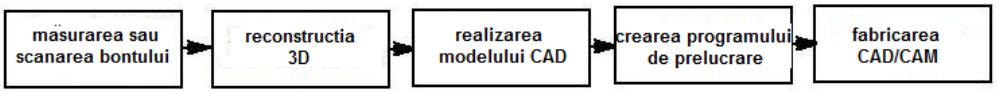

Fig. 2. Fabricarea cu mijloace de tip CAD/CAM

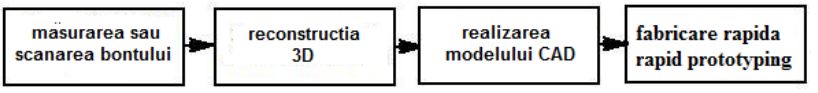

Fig. 3. Fabricarea cu mijloace de fabricare rapidă (sau prototipare rapidă)

Modelul de orteză personalizată studiată în această lucrare permite parcurgerea tuturor etapelor de lucru, de la scanare la prelucrarea imaginilor până la producerea fizică a ortezei. Orteza poate fi fabricată atât cu tehnologii de tip CAD/CAM (fig.2) cât şi cu tehnologii de fabricare rapidă (fig.3). Studiul de faţă a abordat fabricarea cu tehnologii de fabricare rapidă întrucât implică cheltuieli mai reduse.

Principalele etape de lucru parcurse sunt următoarele:

1. Scanarea cu un dispozitiv cu lumină structurată a piciorului unui pacient;
2. Reconstrucţia 3D a piciorului scanat;
3. Prelucrarea imaginii şi obţinerea modelului CAD sau a desenului 3D al unei orteze de picior;
4. Fabricarea ortezei prin introducerea desenului 3D într-o maşină de prelucrare de tip imprimantă 3D.

Orteza abordată în acest studiu face parte din categoria ortezelor corectoare de statică a piciorului, denumite şi susţinători plantari (talonete) recomandate în talalgii, osteofitoza calcaneană, în prevenirea, corectarea şi înlăturarea presiunii în cazul piciorului diabetic ş.a.

Studiul abordează tehnologiile de fabricare rapidă disponibile în România, utilizabile la fabricarea ortezelor şi a componentelor de proteze, din materii prime de tipul maselor plastice.

REZULTATE

1 Scanarea piciorului

Una dintre operaţiunile de obţinere a datelor anatomice personalizate este scanarea. Scanarea permite captarea unor date despre geometria suprafeţelor anatomice, din care se pot obţine, prin prelucrări de imagine, reconstrucţii 3D ale suprafeţelor cercetate.

O posibilă clasificare a metodelor de scanare aplicabile în protezare este următoarea (3, 4):

1. Scanarea cu raze X (computerul tomograf);
2. Scanarea prin rezonanţă magnetică nucleară (RMN);
3. Scanarea cu dispozitive cu laser;
4. Scanarea cu dispozitive cu lumină structurată (distribuită sub formă de linii, puncte).

Fig. 4. Scaner 3D tip Artec

Scopul tomografiei computerizate constă în a produce imagini 2D ale secţiunilor transversale prin corpului unui pacient. Dezavantajele constau în următoarele: pacienţii sunt expuşi unor doze mai mari de radiaţie decât în cazul radiografiilor clasice, echipamentele sunt costisitoare, procedurile sunt mai lente şi mai laborioase decât în cazul radiografiei tradiţionale.

Scanarea prin rezonanţă magnetică (RMN) are unele limite reprezentate de eventuale contraindicaţii (pacemakere, corpuri metalice straine, clipuri anevrismale), claustrofobie (pacientul trebuie sedat), vizualizare slabă a calcificărilor.

Scanarea cu dispozitive cu laser sau cu lumină structurată elimină dezavantajele menţionate în cazurile anterioare. Principalul avantaj constă în eliminarea expunerii la razele X. Totuşi costul unui dispozitiv de scanare cu tot cu programul de reconstruc-

ție 3D este relativ ridicat, fiind cuprins între 10.000 şi 30.000 Euro, în funcție de firma producătoare.

Scanarea piciorului s-a realizat cu un dispozitiv cu lumină structurată care are ca principal avantaj neutilizarea razelor X. S-a folosit în acest scop un scaner 3D portabil tip Artec MH (fig. 4) oferit pentru aplicații de firma Zspotmedia SRL (5). Scanerul are distanța de lucru 0,4 – 1 m şi viteza de achiziție de date 500.000 puncte/sec. Scanarea se execută luând imagini prin deplasarea manuală a scanerului în jurul piciorului (fig. 5).

Fig. 5. Scanarea piciorului

2 Reconstrucția grafică 3D a piciorului

Reconstrucția 3D se referă la obținerea modelului 3D al piciorului pacientului în formatul STL, specific maşinilor de prelucrat prin depunere de material şi imprimantelor de tip 3D. Prelucrarea se poate face de regulă cu un program de tip CAD (AutoCAD, SolidWorks, Catia etc.) sau cu programul de grafică 3D livrat împreună cu scanerul 3D (softul Artec).

Reconstrucția se face mai uşor cu programul ataşat scanerului şi constă în asamblarea imaginilor obținute la scanare, în aşa fel încât să se obțină modelul 3D al piciorului de ortezat (fig.6). Este etapa care consumă cel mai mult timp întrucât operațiunile sunt meticuloase şi cer potrivirea corectă a suprafețelor scanate din unghiuri diferite.

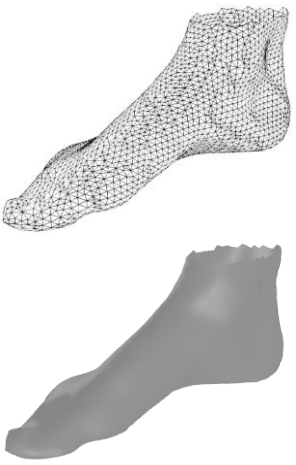

Fig. 6. Reconstrucția grafică 3D a piciorului (3D mesh în stânga şi cu randare în dreapta)

3 Prelucrarea modelelor şi generarea desenului 3D al ortezei personalizate

Prelucrarea modelelor 3D urmăreşte în acest studiu obținerea amprentei piciorului pe suprafața unui semifabricat din care se va confecționa taloneta. Prelucrările se fac cu un program de calculator şi constau în combinarea booleană (în cazul de față operația de scăderea) a modelelor 3D ale piciorului şi semifabricatului ortezei cu scopul obținerii modelului ortezei (fig 7).

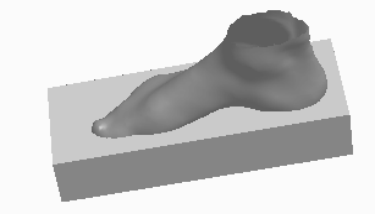

Fig. 7. Modelului piciorului şi modelul semifabricatului

Modelul 3D al semifabricatului are o formă paralelipipedică urmând ca după obținerea amprentei piciorului să fie finisat şi adus la forma finală. Cele două modele

3D se aduc în contact şi apoi din volumul paralelipipedic al semifabricatului ortezei se scade volumul piciorului rezultând orteza cu amprenta piciorului (fig. 8). Prelucrarea modelelor 3D se poate face cu programe de tip CAD care permit combinațiile booleene sau cu programe de grafică 3D (3D Studio Max, Blender, etc.) care permit combinații booleene de suprafețe 3D. În urma prelucrărilor de imagini rezultă modelul sau desenul 3D al ortezei.

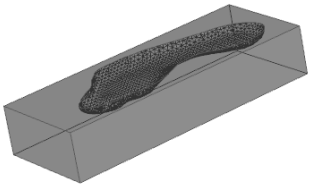

Fig. 8. Amprenta piciorului pe modelul semifabricatului (desenul 3D al ortezei)

După obținerea modelului 3D al semifabricatului ortezei, se ajustează forma ortezei încât să aibă conturul încălțămintei şi se teşesc sau se rotunjesc muchiile ascuțite prin câteva operațiuni de tip CAD. Modelul 3D al ortezei trebuie să fie în format STL.

4 Imprimarea 3D

Înainte de introducerea desenului 3D în imprimantă (5), se face o prelucrare pregătitoare care adaptează formatul desenului (STL) la formatul echipamentul numeric al imprimantei. Desenul 3D se introduce în programul AXON 2, care se vinde împreună cu imprimanta şi care converteşte fişierele STL, feliind modelul ortezei în secțiuni longitudinale (format G-Code), specifice imprimantei.

Desenul 3D al ortezei personalizate se introduce cu ajutorul unui stick de memorie în imprimantă. Imprimanta 3D utilizează ca materie primă, o fibră de material plastic (acrilonitril butadien stirenic ş.a.) cu grosimea de 3 mm, care se topeşte prin încălzire cu ajutorul unui cap termic si apoi se aplică strat cu strat, in funcție de coordonatele X, Y şi Z ale obiectului desenului.

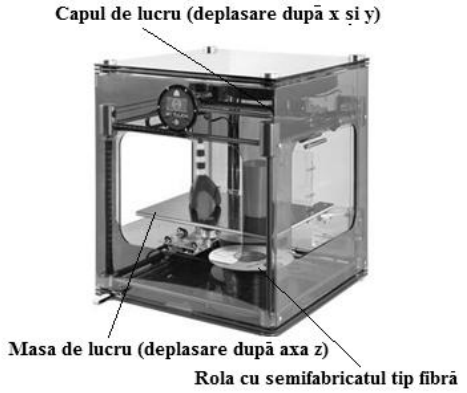

Fig. 9. Imprimantă 3D tip BfB 3D Touch

Imprimanta utilizată, 3DTouch 3DPrinter (fig. 9) este o imprimantă 3D preasamblată low-cost pentru următoarele aplicații: design, proiectare, medicină, arhitectură, inginerie, aplicații tip office sau hobby. Prețul de achiziție este cuprins între 1.500 şi 3.000 Euro. Gabaritul imprimantei este 515x515x590mm, greutatea 37 kg iar consumul de 90 w. Costul imprimării este de 0,06 euro/cm³ imprimat. Gabaritul de prelucrare este de maxim 275x275x210mm. Viteza de imprimare este de 15 mm³/secundă. Figura 10 prezintă forma finală a ortezei fabricate de imprimantă.

Operațiuni la pornirea imprimantei:

1. Conversia desenului 3D al ortezei din format STL, în formatul imprimantei;
2. Transferul modelului în formatul imprimantei, pe un card de memorie;
3. Introducerea cardului în imprimanta 3D şi transferarea datelor;
4. Alegerea unor parametri de lucru şi pornirea imprimantei.

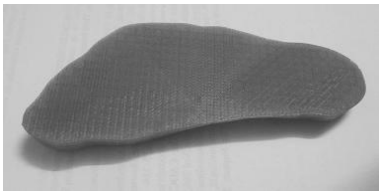

Fig.10 Forma finală a ortezei personalizate fabricată cu imprimanta 3D

DISCUȚII

Din parcurgerea etapelor de lucru se constată că personalul implicat în protezarea cu tehnologii de tip CAD/CAM sau de fabricare rapidă trebuie să aibă cunoştinţe temeinice de proiectare 2D şi 3D, să cunoască programele tip CAD, de reconstrucţie 3D, programele pretabile la operaţii booleene între modelele 3D şi cunoştinţe despre maşinile de prelucrat comandate prin calculator.

Tehnologiile de tip CAD/CAM sunt încă de scumpe la ora actuală şi în consecinţă s-au răspândit destul de puţin în domeniul protezării şi ortezării. Datorită acestui fapt, în Europa şi în SUA se manifestă următoarele tendinţe în dezvoltarea laboratoarelor de protezare cu tehnologii de tip CAD/CAM (6):

1. Dezvoltarea cu precădere a laboratoarelor de protezare bazate pe fabricarea manuală care sunt dotate de regulă cu maşini clasice de prelucrat;

2. Dezvoltarea unor laboratoare de protezare care apelează la calculatoare şi la programe de tip CAD şi uneori la scanere 3D; în aceste laboratoare se obţine forma 3D a suprafeţei anatomice de protezat sau de ortezat dar fabricarea se execută prin subcontractare, la altă organizaţie;

3. Dezvoltarea unor laboratoare de protezare ultramoderne, dotate cu tehnologii complete de tip CAD/CAM sau de fabricare rapidă care produc pe loc toate componentele de protezare;

4. Apariţia unor laboratoare regionale sau centre regionale dotate cu tehnologii complete de tip CAD/CAM sau de fabricare rapidă, care pot fabrica tot felul de componente şi la care apelează prin subcontractare laboratoarele de protezare din regiune, pentru fabricarea protezelor, ortezelor, a dispozitivelor de tehnologie asistivă etc.

În studiul prezentat, costul investiţiilor pentru achiziţionarea unui scaner (11.000 Euro) şi a unei imprimante 3D (3.000 Euro) cu programele aferente, care prelucrează materiale plastice este suportabil pentru un întreprinzător începător. Există şi scanere mai simple, cu performanţe mai slabe dar care se pot achiziţiona la preţuri de circa 300 Euro (7). De fiecare dată la achiziţia tehnicii trebuie analizat tipul componentelor care se pot fabrica şi materialul acestora. Există şi imprimante 3D care pot fabrica unele componente de proteze din oţeluri sau aliaje dar preţul acestora este mult mai ridicat iar materialul de lucru are de multe ori preţuri necompetitive.

CONCLUZII

Studiul arată fezabilitatea aplicării tehnologiilor moderne în producerea unor componente de proteze şi orteze. O mare parte din componentele unor proteze şi orteze se poate fabrica la preţuri competitive cu tehnologii de moderne de fabricare. Prin utilizarea tehnologiilor de tip CAD/CAM sau de fabricare rapidă scade timpul de obţinere a geometriei suprafeţelor anatomice, de proiectare, fabricare şi timpul de modificare a protezelor şi ortezelor. Protezele şi ortezele personalizate au ca principal efect îmbunătăţirea calităţilor ergonomice şi creşterea confortului pacientului. Protezele şi ortezele personalizate au efecte medicale (îndepărtarea handicapului şi

recuperarea funcţionala şi organică), sociale (reintegrare socio-profesională, menţinerea şi prelungirea vieţii active a individului) precum şi psihologice

Volumul investiţiilor necesare în dezvoltarea laboratoarelor de protezare cu tehnologii de fabricare rapidă, pentru fabricarea de componente din materiale plastice este suportabil pentru un întreprinzător începător. Piaţa internaţională a produselor de protezare şi ortezare este în continuă creştere, atât prin creşterea volumului de vânzări cât şi prin diversificarea acestora (8).

NOUTĂŢI

ACTIVITATEA ANTIMICROBIANĂ A HIDROGELULUI POLICATIONIC

În scopul reducerii riscului infecţiilor asociate dispozitivelor medicale implantabile, Li P. şi colab. au dezvoltat un hidrogel pe bază de chitosan, cu proprietăţi antimicrobiene, eficace împotriva unor bacterii precum *Pseudomonas aeruginosa, Escherichia coli, Staphylococcus aureus*. Majoritatea materialelor folosite actualmente nu corespund simultan cerinţelor legate de activitatea antimicrobiană şi biocompatibilitate. Activitatea antimicrobiană a hidrogelului policationic se datorează capacităţii de aspirare a unor porţiuni din membrana microbiană anionică în nanoporii interni ai hidrogelului, determinând disrupţia membranei microbiene şi moartea celulară. Studii animale au demonstrat biocompatibilitatea polimerului şi lipsa toxicităţii pentru celulele epiteliale. (Li P, Poon YF, Li W, Zhu HY, Yeap SH, Cao Y, et al. A polycationic antimicrobial and biocompatible hydrogel with microbe membrane suctioning ability. *Nat Mate*r.2011;10(2):149-56).

BIOCOMPATIBILITATEA FAŢETELOR VESTIBULARE DIN RĂŞINI DIACRILICE COMPOZITE

Raluca Dima
Universitatea Oradea
Facultatea de Medicină şi Farmacie Oradea
Departamentul de Stomatologie

CLINICAL BIOCOMPATIBILITY OF DIACRILIC RESIN VENEERS (Abstract): The great variety of modern composite resins developed recently by manufacturers, offered to clinicians multiple choices of restoring esthetic of frontal teeth. **Material and methods**. The present study was performed over a period of 8 months. The patients were devided in two groups: A consisted of patients that received indirect veneers; and B consisted of patients that received direct veneers. **Results**. The clinical evaluation showed no major differences between group A and B, concerning the gingival recesion data and also concerning the plaque index. **Conclusions**. The data obtained from the study made us assess that direct and indirect composite materials have a clinically acceptable result in terms of biocompatibility when used for frontal veneers. **Key words**: RESIN VENEERS, BIOCOMPATIBILITY, GINGIVAL RECESSION.

Varietatea de materiale compozite moderne şi adezivi au oferit în ultimii ani facilităţi pentru îmbunătăţirea aspectului estetic al dinţilor frontali.

Metoda directă de faţetare are avantaje evidente de costuri şi timpi clinici dar şi dezavantaje legate de stabilitatea coloristică, rezistenţă şi biocompatibilitate.

Compozitele au fost iniţial gândite pentru a reface estetica şi funcţionalitatea dinţilor frontali, dar ulterior ramforsarea şi dezvoltarea unor materiale cu încărcătură mai rezistentă au extins aplicarea lor şi la zonele laterale.

Deşi nu sunt, în general, atât de rezistente ca şi restaurările ceramice sau integral ceramice, unele studii au dovedit că răşinile diacrilice compozite (RDC) sunt performante şi pentru zona laterală, cavităţile de clasă I şi II, după Black (cit.1).

Conform datelor din literatură (2, 3), comparaţia între rezistenţa mecanic a faţetelor directe din RDC, nu a dovedit rezultate mai slabe decât cea a echivalentelor, realizate în laborator.

MATERIAL ŞI METODE

Studiul a fost realizat în cabinetul de medicină dentară pe o perioadă de 8 luni şi a comparat biocompatibilitatea faţetelor vestibulare directe şi indirecte realizate din RDC. Lotul de 36 de pacienţi a fost împărţit în 2 grupuri: primul a inclus pe cei protezaţi după metoda indirectă din material compozit SRADORO, iar al doilea, pacienţii pentru care au fost realizate faţete după metoda directă cu răşină compozită Empress Direct. SRADORO® este compozitul folosit în acest studiu, având o umplutură de 65% şi un dimetacrilat alifatic –

aromatic UDMA (3). Fațetarea directă s-a realizat cu compozitul cu nanoumplutură IPS Empress ® Direct compus din nanomer dimetacrilat 20 – 21% (17% transparent). Umplutura a fost compusă din sticlă de bariu, florură de itterbium, dioxid de siliciu, şi copolimeri în masă de 77,5 – 79% nuanțe opalescente şi 83% culori normale. Masa totală de umplutură anorganică a fost de 79 - 59%, iar dimensiunea particulelor între 40 mm şi 3000 mm, cu o medie de 550 mm. Stratificarea s-a realizat în conformitate cu indicațiile producătorului. Examinarea clinică a fost realizată prin calcularea adâncimii şanțului gingival şi indicele de placă (IP). Toate valorile au fost clasificate şi supuse testului de analiză statistică „t Student".

REZULTATE

Fiecare grup a fost compus din câte 18 pacienți. Grupul A, la care am examinat sănătatea gingivală a 18 fațete vestibulare realizate din SRADORO, a inclus: 10 bărbați şi 8 femei cu vârsta medie 38,7 ani; iar în B au fost incluşi 7 bărbați şi 11 femei, cu vârsta medie de 40,5 ani. S-a examinat ataşamentul gingival vestibular la 18 fațete realizate folosind nanocompozitul Empress Direct.

În cazul tuturor pacienților incluşi în studiu, la marginea preparației s-a realizat un chanfrein uşor, juxtagingival şi supragingival, iar etalarea şanțului gingival s-a obținut preoperator cu ajutorul unui fir 0,01 Ultrapak, astringetul folosit fiind clorura de aluminiu. Toți dinții luați în studiu au fost vitali, iar relațiile de ocluzie diferite nu au constituit un obiect al acestui studiu. Valorile medii ale recesiunii gingivale în grupul A la 1, 3 şi 6 luni, postoperator au fost 1,15 (± 0,95), 0,73 (±0,68) şi 0,6 (±0,48). Comparația în cadrul celor 3 examinări la grupul A postoperator a fost semnificativă statistic: astfel s-a înregistrat o scădere a valorii p 0,001 şi 0,000, respectiv la 1 şi 3 luni. Schimbarea lui p între 3 şi 6 luni nu a prezentat o valoare semnificativă statistic ($p > 0,05$) (tab. I).

TABELUL I

Unele date de comparație între recesiunea gingivală verticală (în mm) la grupul A

Grupul A (Perechea)	Timpul de comparație	Valoarea medie	Deviația standard	t	p
1	VR 00 VR 01	4,3 1,15	1,174 0,947	12,13	0,000
2	VR 00 VR 03	4,3 0,72	1,174 0,6781	14,04	0,000
3	VR 00 VR 06	4,3 0,6	1,174 0,475	16,67	0,000
4	VR 01 VR 03	1,350 0,752	0,947 0,678	3,86	0,001
5	VR 01 VR 06	1,350 0,600	0,947 0,4757	4,56	0,000
6	VR 03 VR 06	0,725 0,600	0,6781 0,4757	1,097	0,287

Pentru pacienții din grup B, recesul gingival la 1, 3 şi 6 luni a prezentat o valoare medie de 0, 85 (±0,56), 1,25 (±0,79) şi 1,15(±0,61), având o semnificație statistică de p 0,001 şi 0,007 la 1 şi 3 luni. Între 3 şi 6 luni rezultatele nu au avut diferențe semnificativ statistice (p > 0,005) (tab. II).

În cadrul aceluiaşi grup de pacienți comparația gradului de retracție gingivală verticală a evidențiat că la început şi după o lună, a rezultat o valoare semnificativă statistic (p ≤ 0,05). La 3 şi 6 luni postoperator, valorile s-au menținut semnificativ statistic (p < 0,05). La compararea între grupurile de pacienți, nu s-a obținut nici o valoare semnificativă statistic între 3 şi 6 luni; dar aceasta a fost prezentă între momentul 0 şi 3 luni (tab. III).

TABELUL II

Unele date de comparație între recesiunea gingivală verticală (în mm) la grupul B

Grupul B (Perechea)	Timpul de comparație	Valoarea medie	Deviația standard	t	p
1	VR 00	4,200	1,0052		
	VR 01	0,850	0,5643	1,6833	0,000

	VR 06	1,150	0,6091	1,285	0,214

TABELUL III

Evaluări privind comparația retracției gingivale (în mm) pentru lotul de pacienți incluşi în studiu

Timp (luni)	Media		Deviația standard		t'	p
	Grupul A	Grupul B	Grupul A	Grupul B		
1	1,150	0,850	0,9473	0,5643	2,028	0,050
3	0,725	1,250	0,6781	0,7864	-2,261	0,030
6	0,600	1,150	0,4757	0,6091	-3,182	0,003

Indicele de placă, urmărit în evoluție, a prezentat valori diferite în relație cu grupul şi perioada evaluată.

Creşterile de la momentul 0 la 1, 3 şi 6 luni au fost aceleaşi la ambele grupuri, iar diferențele între cele 3 momente nu au prezentat o valoare semnificativă statistic în ambele grupuri. Aceleaşi rezultate nesemnificative statistic au fost obținute şi la compararea între grupul A şi B (p>0,05) (tab. IV, V).

TABELUL IV

Elementele de comparaţie pentru indicele de placă în grupul A

Grupul A (Perechea)	Timpul de comparaţie	Valoarea medie	Deviaţia standard	t	p
1	PI 00	1,420	0,3636		
	PI 01	0,890	0,3978	3,818	0,001
2	PI 00	1,420	0,3636		
	PI 03	0,790	0,2594	7,471	0,000
3	PI 00	1,420	0,3636		
	PI 06	0,700	0,3340	8,786	0,000

TABELUL V

Elementele de comparaţie pentru indicele de placă în grupul B

Grupul B (Perechea)	Timpul de comparaţie	Valoarea medie	Deviaţia standard	t	p
1	PI 00	1,540	0,3235		
	PI 01	1,050	0,3441	7,074	0,001

DISCUŢII

Sistemele adezive moderne şi răşinile nanocompozite oferă clinicianului mijloace rapide pentru a reda pacientului un zâmbet estetic, iar eventualele fracturi ulterioare datorate mai slabei rezistente mecanice, pot fi reparate uşor, comparativ cu feţetele ceramice.

Principalul dezavantaj al feţetării directe este însă contracţia de polimerizare a materialului folosit la restaurare, care duce în final la carii secundare şi acumulare de placă bacteriană în spaţiile rezultate.

Feţetele realizate după metoda indirectă din RDC sunt mai fiabile decât cele directe (4, 5). Principalele avantaje constau în gradul lor superior de finisare şi structura mai compactă rezultată din polimerizarea baro, termo, ultravioletă sau combinată, care creşte gradul de conversie rezultând o

structură mai rezistentă. Este cunoscut faptul că gradul de conversie monomer – polimer creşte atunci când se folosesc monomeri multifuncţionali, oferind mai multe poziţii reactive care vor creşte lungimea lanţurilor de polimer.

Un mijloc suplimentar de creştere a rezistenţei poate fi obţinut prin ramforsarea cu sticlă sau fibre de polietilenă (6, 7). Determinarea lungimii şanţului gingival a fost realizată cu sonda parodontală gradată, examinare realizată la intervalele date de timp, de către acelaşi examinator, iar faptul că au fost solicitări pentru reexaminări a stimulat pacienţii în a-şi întreţine o igienă corespunzătoare pe toată perioada studiului, fenomen observat şi de către alţi autori (8). Pacienţii erau în proporţie de 100% fumători şi consumatori de cafea, iar condiţia de includere în studiu a fost un maxim 8 la indicele de placă, deci prezentau o igienă satisfăcătoare şi înainte de tratament.

Studiul a demonstrat că ambele metode, directă şi indirectă, de faţetare au prezentat rezultate acceptabile clinic, şi comparabile cu datele din literatură, astfel că biocompatibilitatea a fost demonstrată clinic în cazul materialelor compozite utilizate (9).

Studiul s-a desfăşurat însă pe o perioadă scurtă, "îmbătrânirea" cunoscută a compozitelor, cauza frecventă a problemelor parodontale create de acestea, neavând încă loc, aspect relevat şi de literatura de specialitate a ultimilor ani (10).

CONCLUZII

Fiecare restaurare e unică în termeni specifici materialului din care este realizată, cum ar fi: rezistenţă mecanică, la uzură, toleranţa la umiditate, stabilitate dimensională şi coloristică. La aceştia se adaugă factorii ce ţin de procedeul tehnic de realizare, volumul restaurării, adâncimea preparaţiei, uşurinţa accesului în zonele de restaurat.

Datele clinice acumulate cu ajutorul studiului au permis a se considera că restaurarea directă corect realizată în condiţii asemănătoare, este practic la fel de corespunzătoare clinic şi estetic ca şi cea realizată indirect în laborator din RDC la momentul zero al aplicării ei în cavitatea bucală. Eventualele diferenţe de finisare şi estetică se pot explica după o perioadă de timp print-o placofilie mai accentuată sau o pigmentare marginală.

Diferenţa notabilă între faţetele directe şi cele indirecte, constă în preţul de cost şi probabil în rezistenţa în timp, coloristică sau probleme de mecanică.

Principalul factor de luat în considerare, este gradul de igienă dentară care a fost satisfăcător în cazul tuturor pacienţilor examinaţi, iar plasarea subgingivală a marginilor preparaţiei afectează sănătatea gingivală, dar faţetele, prin grosimea lor redusă, sunt de preferat coroanelor integrale.

NOUTĂȚI

LIPOZOMII- NANOCARRIERS PENTRU ANTITUBERCULOASE

Tuberculoza (TB) este o boală infecțioasă care rămâne departe de a fi eradicată şi controlată. Tratamentul TB este grefat de o complianță scăzută fiind un tratament pe termen lung, cu o combinație de antituberculoase care generează apariția de multiple reacții adverse. Complianța scăzută favorizează apariția de tulpini rezistente şi creşte costurile terapiei. În condițiile în care nu au fost descoperite noi antibiotice antituberculoase devine prioritară dezvoltarea de modalități terapeutice care să crească complianța pacienților la terapiile curente.Un grup de cercetători din Portugalia au demonstrat avantajele utilizării lipozomilor ca sisteme nanocarriers pentru antituberculoase de prima şi a doua linie. Ei au arătat că lipozomii sunt structuri veziculoase auto-închise compuse din fosfolipide care pot încorpora medicamente hidrofile, hidrofobe sau amfifile şi care sunt recunoscute specific de către macrofage. Suprafața lipozomilor poate fi modificată prin adăugarea de liganzi (anticorpi şi alte molecule), care cresc specific capacitatea de a recunoaşte şi a se leaga de celulele-țintă. Consecința creşterii specificității lipozomilor pentru o celulă țintă determină acumularea lor preferențial în țesuturi bolnave şi realizarea unor concentrații mai mici în țesuturile sănătoase care vor fi astfel salvate de un eventual efect toxic al antibioticului livrat de aceste nanoparticule. Astfel, lipozomii reduc toxicitatea drogurilor încapsulate, cresc biodisponibilitatea antibioticelor determinând creşterea eficienței tratamentului şi reducerea duratei acestuia. În plus, lipozomii au avantajul de a fi biocompatibili, biodegradabili şi non-imunogeni deoarece pentru obținerea lor se pot utiliza compuşi endogeni (cum ar fi elementele constitutive de surfactant pulmonar). Compoziția lipozomilor poate fi, de asemenea, reglată pentru a selecta cea mai favorabilă cale de administrare. De exemplu, în caz de TB pulmonară, administrarea inhalatorie în loc de calea intravenoasă ar creşte complianța pacienților la terapie, diminuând abandonul şi riscul apariția rezistenței. Administrarea inhalatorie de lipozomi încărcați cu medicamente anti-TB are avantajul de a realiza concentrații locale ridicate de antituberculoase în macrofagele alveolare, de a reduce efectele adverse sistemice, precum şi de a reduce frecvența administrărilor. Aceste proprietăți permit utilizarea lipozomilor în tratamantul TB ca o alternativă a tratamentului curent (Pinheiro M., Lúcio M., José LFC Lima. Liposomes as Drug Delivery Systems for the Treatment of TB. *Nanomedicine*. 2011:1413-1428).

Cătălina Luncă

INCLUZIA PALATINALĂ A CANINULUI MAXILAR – PREZENTARE DE CAZ

Loredana Golovcencu[1], V.V. Costan[2]
Universitatea de Medicină şi Farmacie „Gr. T. Popa" Iaşi,
Facultatea de Medicină Dentară
1. Disciplina Ortodonţie şi Ortopedie dento-facială
2. Disciplina Chirurgie maxilo-facială

PALATALLY IMPACTED CANINES – CASE REPORT (Abstract). Maxillary canines have the longest period of development, the deepest area of formation and the most difficult path of all teeth. The maxillary canines are the most likely to remain unerupted or impacted. The maxillary permanent canine is considered important by virtue of its place in the scheme of functional occlusion and its contribution to facial appearance. We successfully orthodontically treated two cases with palatally impacted canines. Although both cases had palatally impacted canines, they were different due to canine position and angulation. **Key words**: PALATALLY IMPACTED CANINES, ORTHODONTIC TREATMENT, CANINE ANGULATION

Incluzia dentară este reţinerea intraosoasă sau submucoasă a unui dinte complet format, după perioada normală de erupţie, sacul pericoronar nefiind deschis. Incluzia de canin superior este întâlnită în populaţie cu o frecvenţă de 0,9-2,2% (1). Dachi şi Howell (2) au arătat că această condiţie este de 2,3 ori mai frecventă la sexul feminin comparativ cu sexul masculin. În 85% din cazuri caninul maxilar este inclus palatinal, iar la 8% din subiecţi incluzia este bilaterală. În ceea ce priveşte etiologia incluziei palatinale a caninului maxilar au fost emise două teorii: teoria „absenţei ghidajului dentar" şi teoria „factorilor genetici". Teoria „ absenţei ghidajului dentar" se referă la existenţa unui exces de spaţiu în zona apicală maxilară, caninul pierzând astfel ghidajul reprezentat de rădăcinile dinţilor vecini. Teoria „genetică" susţine existenţa unor tulburări de dezvoltare ale lamei dentare, tulburări care vor determina poziţionarea anormală a mugurelui caninului superior (3,4). Unii autori citează înghesuirea drept cauză locală a incluziei caninului maxilar, dar această condiţie este mai frecventă în cazul caninilor incluşi vestibular (5).

PREZENTAREA CAZURILOR

CAZUL 1

Pacient I.S., în vârstă de 25 de ani, sex feminin, se prezintă cu persistenţa caninului temporar dreapta. La examenul intraoral se constată prezenţa caninului temporar drept şi absenţa caninului maxilar permanent în cadranul 1. La inspecţie şi palpare se remarcă o uşoară bombare a mucoasei, de consistenţă dură, retroincisiv lateral superior drept. Pacienta prezintă arcade den-

tare relativ corect aliniate şi ocluzie echilibrată clasa I Angle (fig. 1).

Fig.1. I.S., model maxilar pretratament ortodontic

Ortopantomografia arată prezența caninului maxilar inclus cu suprapunerea completă a coroanei peste imaginea rădăcinii incisivului lateral. Rădăcina incisivului lateral nu prezintă rizaliză. Angulația caninului este de 45º, ceea ce conferă cazului un prognostic rezervat (fig. 2).

Fig. 2. I.S., ortopantomografie pretratament

Obiectivele tratamentului chirurgical ortodontic au fost: 1) obținerea spațiului pe arcadă necesar alinierii caninului; 2) descoperirea chirurgicală a caninului inclus; 3) tracțiunea lentă a caninului spre ocluzal, apoi spre distal pentru a-l degaja de sub incisivul lateral; 4) tracțiune vestibulară şi aliniere pe arcadă. Tratamentul ortodontic a constat în aplicarea unui aparat fix *straight-wire* 0.025x0.028-inch şi a unui arc palatal modificat pentru tracționarea caninului (fig. 3).

Fig. 3. I.S., tracționarea caninului inclus

Durata totală a tratamentului a fost de 23 luni, modelele şi ortopantomografia arătând o încadrare corectă pe arcadă a caninului maxilar drept (fig. 4,5). Deşi prognosticul a fost rezervat datorită profunzimii incluziei şi angulației nefavorabile, tratamentul s-a desfăşurat cu prejudicii parodontale minore, înregistrându-se o recesiune gingivală de numai 0,75 mm pe fața palatinală a caninului.

Fig. 4. I.S., model de studiu post-tratament ortodontic

Fig. 5. I.S., ortopantomografia post-tratament ortodontic

CAZUL 2

Pacient M.C., 13 ani, sex feminin, se prezintă cu absența caninului temporar și permanent drept, linia interincisivă superioară deviată spre dreapta și micșorarea spațiului necesar dintelui 1.3. Ocluzia echilibrată, clasa I Angle. La examenul intraoral se constată o ușoară bombare la nivelul bolții palatine înapoia incisivului lateral drept (fig. 6).

Fig. 6. M.C., aspect pretratament ortodontic

Ortopantomografia arată prezența caninului superior drept inclus, înclinat la 45º, imaginea sa suprapunându-se cu cea a incisivului lateral (fig. 7).

Etapele tratamentului au fost: 1) aplicarea unui aparat fix *straight-wire* 0.025x 0.028-inch și a unui arc quad-helix modificat; 2) recâștigarea spațiului pe arcadă pentru caninul superior; 3) descoperirea chirurgicală a caninului și tracționarea lui la arcul quad-helix;, 4) tracțiunea spre vestibular a caninului și alinierea lui pe arcadă. Durata totală a tratamentului a fost de 25 de luni (fig. 8, 9).

Fig. 7. M.C., ortopantomografia pretratament

Fig. 8. M.C., aspect postortodontic

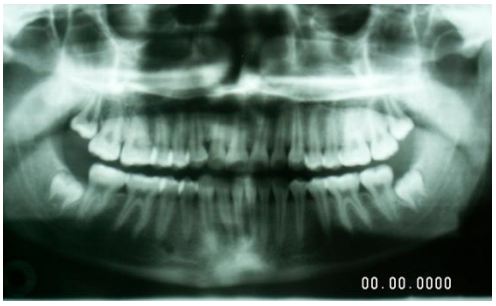

Fig. 9. M.C., ortopantomografie post-tratament ortodontic

DISCUȚII

Incluzia palatinală a caninului maxilar reprezintă o patologie comună în practica

ortodontică, dar care este descoperită târziu de către pacienți din cauza persistenței caninului temporar. În cazurile în care s-a pierdut totuşi caninul temporar şi în absența tratamentului ortodontic, se poate produce devierea liniei interincisive şi rotația premolarului 1 limitrof edentației, ceea ce duce la pierderea spațiului necesar caninului permanent inclus. Un canin inclus palatinal poate, în unele cazuri, să producă rizaliza rădăcinii incisivului lateral maxilar, şi chiar a incisivului central. În tratamentul incluziei de canin maxilar hotărâtoare este poziția, profunzimea, angulația şi raportul caninului cu dinții adiacenți. Un rol deosebit de important în stabilirea diagnosticului şi conduitei terapeutice îl are examenul radiologic care trebuie să includă obligatoriu ortopantomografia, iar în cazurile mai dificile tomografia computerizată cu reconstrucție 3D. În primul caz prezentat caninul inclus palatinal era din grupa a 3-a, conform clasificării lui Becker (6), ceea ce înseamnă un canin situat înalt în osul maxilar, paralel cu linia arcadei. În acest caz prognosticul a fost destul de rezervat, dar, la final, rezultatul obținut a fost mulțumitor din punct de vedere ortodontic şi parodontal. În cel de-al doilea caz a fost nevoie de recâştigarea spațiului pierdut prin extracția caninului temporar şi corectarea devierii liniei mediane, dar caninul inclus a fost situat mai aproape de linia arcadei în plan vertical şi transversal.

Tratamentul incluziei palatinale de canin este un tratament complex, interdisciplinar şi care trebuie să ia în calcul toate aspectele anatomo-clinice legate de dintele inclus şi de dinții limitrofi, durata probabilă a tratamentului şi raportul risc/beneficiu.

ASSESSMENT OF THE CONGENITAL SYPHILIS PREVENTION PROGRAMS (Abstract): The Romanian program for the management and screening of syphilis includes the recording, follow-up, and antenatal care of pregnant women. It aims at testing all pregnant women for syphilis with the help of VDLR (Venereal Disease Research Laboratory) or RPR (Rapid Plasma Reagin) tests, and in the women with positive tests to confirm the results by treponemal tests (treponemal antibodies): THPA (*Treponema Pallidum* Hemagglutination), FTA-Abs (Fluorescent Treponemal Antibody with Absorption), ELISA-Captia-IgM, and Western Blotting-IgM. In the pregnant women with positive tests two doses of 2.4 million units of penicillin G benzathine were administered at 5 days interval. These pregnant women are in the evidence of a specialist (obstetrician, dermatologist), and District Department of Public Health, and required to come for another serology test in 3 months. In case they still test positive, the same treatment is applied at the beginning of the third trimester of pregnancy. **Aim:** To assess the outcome of congenital syphilis prevention programs in Iasi, Romania. **Material and methods:** In the interval 2005-2011, in the Iasi town, 84 RPR positive pregnant women were recorded. There was no significant difference in the number of pregnant women residing in urban as compared to rural areas. Most of these women were from poor social environments and had a low level of education. The diagnosis of acquired syphilis was made by serological tests as most pregnant women presented in the period of syphilis latency, being asymptomatic. All pregnant women followed the treatment, and were tested periodically. Ultrasound examination was normal in all women (no changes suggestive of fetal malformations). **Results:** Free clinical, laboratory, and ultrasound investigations, history taking, psychological assessment, sex education, rapid identification of contacts of known patients, follow-up of the interaction between health care providers and syphilitic pregnant women, booklets, and leaflets altogether made that in the last 3 years (2008-2010) no new case of congenital syphilis to be reported in the study area. **Conclusions:** Encouraging women to attend antenatal care early in their pregnancy is essential, this way all pregnancy-related problems (syphilis included) could be managed.
Key words: PREGNANCY, PRENATAL DIAGNOSIS, CONGENITAL SYPHILISY

Prevenirea sifilisului congenital nu este dificilă, însă există unele dificultăţi operaţionale de nerespectare a programelor de investigaţie şi a tratamentului prenatal.

Gestionarea cazurilor pozitive este dificil de pus în aplicare atunci când gravidele

nu se prezintă deloc, când prima lor vizită la clinica prenatală se face prea târziu, uneori chiar înainte de naştere. Unele dintre ele consideră că o singură vizită la medicul de familie în timpul sarcinii este suficientă şi nu acordă importanţă examenului ecografic, analizelor curente din timpul sarcinii sau aplicării tratamentului corespunzător în cazul celor care au avut rezultatul pozitiv la testul VDRL (Venereal Disease Research Laboratory) sau RPR (Rapid Plasma Reagin).

În acelaşi timp, clinicianul nu a avut un sistem de urmărire şi dispensarizare a gravidelor VDR/ RPR pozitive, care nu s-au întors după rezultatele lor şi nici posibilitatea de a le obliga să urmeze tratamentul atât pe femeia depistată cât şi pe partenerul ei sexual. O altă metodă de prevenire ar putea fi aplicarea sistemului de poliţie sanitară care exista în România înainte de 1989.

Acesta presupune încurajarea femeilor de a participa la îngrijire prenatală şi dispensarizare la medicul de specialitate încă de la începutul sarcinii, oferind testare serologică gratuită, examene clinice şi paraclinice periodice, astfel încât rezultatele să fie disponibile imediat şi gravidele sero-pozitive să poată fi tratate împreună cu partenerul sexual, dacă şi acesta este seropozitiv.

A doua testare, mai târziu, în timpul sarcinii la începutul trimestrului III, ajuta la gestionarea şi îmbunătăţirea calităţii asistenţei medicale faţă de sifilis în timpul sarcinii, naşterii precum şi în perioada neonatală, şi în acelaşi timp la prevenirea sifilisului congenital.

Diverse metode au fost urmărite pentru acest studiu dintre care: examinări clinice şi para clinice, examenul ecografic, anamneză, evaluare psihologică, interviuri informatoare şi observaţii ale interacţiunii dintre furnizorii de servicii medicale şi gravide cu boala sifilitică, colectarea de date din materiale publicate, rapoarte, ghiduri ale furnizorilor de servicii, manuale de instruire şi alte documente .

Elementele de bază au fost testarea VDRL/RPR, confirmarea prin TPHA gratuită la toate femeile gravide, furnizarea de informaţii despre îngrijirea necesară şi despre servicii medicale corespunzătoare, tratamentul femeilor gravide sero-reactive realizat de asistente medicale la clinica de specialitate obstetricală, prevenirea sifilisului congenital şi notificarea partenerului sexual şi convingerea lui de a fi testat serologic pentru diagnosticarea şi tratarea la clinica de dermatologie.

CAZ CLINIC

În anul 2006 gravida S.A. în vârstă de 15 ani, diagnosticată cu sarcină 7 săptămâni, sifilis latent, urmează tratament cu benzathin penicilină G. La câteva zile după tratament se internează la maternitate cu diagnosticul de Sarcină luna a II-a - avort incomplet. Se aplică tratamentul chirurgical (chiuretaj uterin evacuator şi hemostatic), tratament medicamentos (antibiotice) se practică examenul anatomo-patologic al produsului de chiuretaj în microscopie optică nu se identifică modificări celulare care să incrimineze agentul sifilisului *Treponema pallidum*.

Pacienta urmează tratament, efectuează invistigaţii periodice pentru sifilis, persistând pozitivitatea TPHA, iar soţul ei prezintă serologie negativă.

În anul 2010 pacienta este gravidă din nou, fiind dispensarizată de medici specialişti, făcând analize periodice şi examene ecografice (fig.1) din care rezultă vârsta sarcinii, evoluţie normală, În luna ianuarie

2011 aceasta dă naştere unui nou născut viu,de sex feminin, cu o greutate de 2950 de grame, apgar = 9, fiind identificat cu serologie sifilitică negativă.

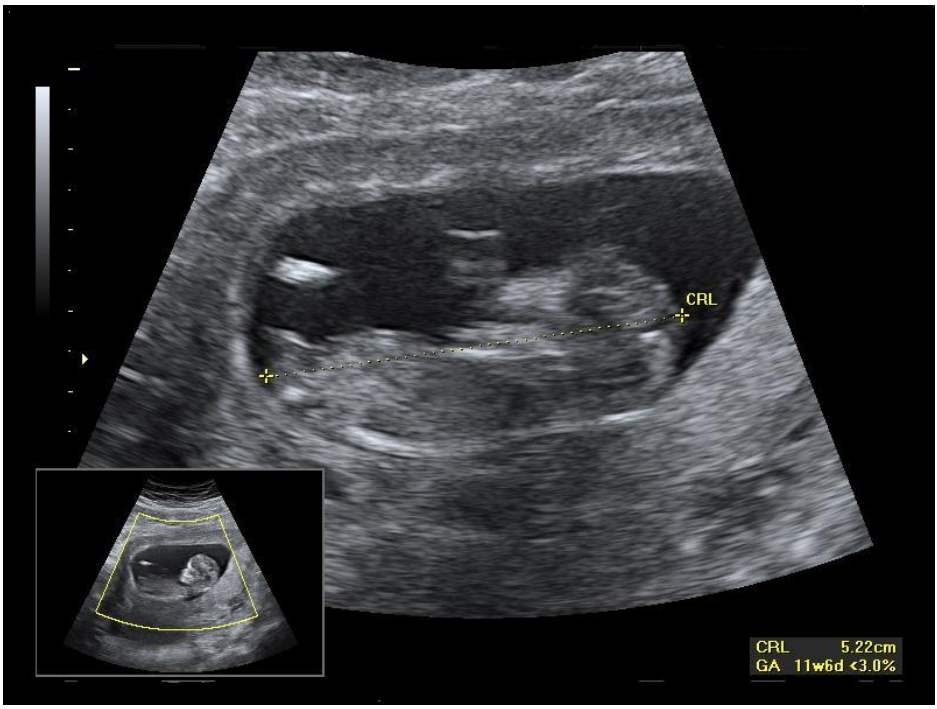

Fig. 1 .Examen ecografic din care rezultă vârsta sarcini cu evoluţie normală

DISCUŢII

Programul de management şi screening al sifilisului prenatal din România cuprinde înregistrarea, luarea în evidenţă, supravegherea gravidelor şi îngrijirea lor prenatală.

Programul îşi propune să testeze toate gravidele pentru sifilis folosind testele VDRL (Venereal Disease Research Laboratory) sau RPR (Rapid Plasma Reagin), iar pentru cele cu rezultate pozitive să realizeze confirmare prin teste treponemice (anticorpi antitreponemici): testele TPHA (**Treponema Pallidum Hemagglutination**), FTA–Abs (Fluorescent Treponemal Antibody with Absorption), ELISA-Captia-IgM, Western Blotting- IgM.

La prima lor vizită, pentru femeile care au prezentat rezultate pozitive s-a aplicat un tratament cu două doze a 2,4 milioane unităţi de benzathin penicilină G la interval de 5 zile. Gravidele au fost luate în evidenţă la medicul de specialitate (Obstetrician, Dermatolog) şi la DSP, urmând să revină la controlul serologic la 3 luni, unora dintre ele reaplicându-li-se aceeaşi schemă de tratament la începutul trimestrului III al sarcinii.

CONCLUZII

În perioada 2005-2011 în care au fost luate în evidentă în Iaşi 84 de gravide cu RPR pozitiv, nu a existat o diferenţă mare de procentaj între gravidele provenite din mediul rural şi cele provenite din mediul

urban. Majoritatea au fost din medii sociale precare şi cu un nivel scăzut al educaţiei.

În practica de rutină, diagnosticul sifilisului dobândit, inclusiv al gravidelor, se face cu ajutorul testelor serologice, deoarece majoritatea pacientelor au venit în perioada de latenţă a bolii şi sunt asimptomatice.

Toate gravide dispensarizate au urmat tratament şi au efectuat analize periodice. Examenul ecografic a fost normal la toate, fără modificări care să arate malformaţii fetale, iar în ultimi 3 ani (2008, 2009, 2010) nu s-a declarat nici un caz nou de sifilis congenital în judeţul Iaşi.

NOUTĂȚI

DABIGATRAN ETEXILATE – UN NOU INHIBITOR ORAL DE TROMBINĂ

Anticoagularea orală de lungă durată este indicată pentru o serie de boli cardiovasculare: prevenţia tromboembolismului la pacienţii cu fibrilaţie atrială, purtătorii de proteze valvulare mecanice, infarctul miocardic acut, tratamentul şi profilaxia trombozei venoase profunde. În ultimii 60 de ani, antagoniştii de vitamină K (warfarină, acenocumarol, phenprocoumon, fluindione) au fost prescrişi pe scară largă. În tot acest timp, utilizarea anticoagulantelor orale a fost grevată de o serie de inconveniente: lungimea perioadei până la intrarea în acţiune, care duce la creşterea perioadei de spitalizare, şi, deci, a costurilor, fereastra terapeutică îngustă, interacţiunile frecvente cu alte clase de medicamente şi riscurile de sângerare. Dabigratan etexilate şi derivatul său activ dabigratane vor reprezenta o alternativă terapeutică eficientă la antivitaminele K. Dabigratan este un inhibitor direct de trombină şi are un timp de înjumătăţire de 14 – 17 ore, ceea ce permite administrarea sa în două prize pe zi (150 mg de 2 ori pe zi). Dabigatran s-a dovedit eficient şi sigur în profilaxia trombozei venoase profunde (sudiul RE-NOVATE, efectuat la pacienţi spitalizaţi pentru fractură totală de şold) şi în scăderea riscului de sroke la pacienţii cu fibrilaţie atrială (studiul RE-LY) (Hankey GJ, et al. Dabigatran etexilate – a new oral thrombin inhibitor. *Circulation* 2011; 123: 1436-50).

2. Serviciul de Anatomie Patologică, Spitalul Clinic Universitar „Sf. Spiridon" Iaşi

MALHERBE'S CALCIFYING EPITHELIOMA – COMMENT ON TWO CLINICAL CASES (Abstract): Malherbe's calcifying epithelioma (also called trichomatricoma, pilomatrixoma or pilomatricoma) is an uncommon benign cutaneous tumor, which takes the form of a solitary, firm, asymptomatic, slowly growing nodule, developed subcutaneously on the face, neck, or proximal upper extremity. With an incidence of 1/800-1000 cutaneous tumors, pilomatricoma is more common in the first two decades of life, predominantly affecting the women. Multiple locations and associations between this entity and other diseases such as Steinert's myotonic dystrophy or Gardner syndrome have been described in the literature. The clinical diagnosis is often difficult, most cases being mistaken as sebaceous cysts. The treatment of choice is surgical excision. Incomplete surgical excision can be followed by local recurrence because most lesions are poorly defined; therefore, patients should be monitored after surgical excision to prevent this from happening. We present two cases admitted in 2010 and 2011 to the Iasi Department of Oral and Maxillo-Facial Surgery: a 55-year-old female patient with a Malherbe's calcifying epithelioma located in the left temporal region, and a 51-year-old female patient with the same disease but located in the left masseter region. **Key words:** MALHERBE'S CALCIFYING EPITHELIOMA, PILOMATRICOMA, PILOMATRIXOMA

Pilomatrixomul (pilomatricomul sau epiteliomul calcificat Malherbe) este o tumoră benignă a matricii foliculului pilos. Incidența maximă a fost semnalată în primele două decade de viață dar şi între 50-65 ani, predominant la femei. Localizările cele mai frecvente ale pilomatrixomului sunt: capul, gâtul, fața şi membrele superioare. De obicei, se prezintă ca un nodul nedureros fiind adesea confundat preoperator cu un chist epidermoid (sebaceu). Prima descriere a acestei entități clinice a fost publicată în 1880 de către Malherbe şi Chenantais sub denumirea de epiteliom calcificat. Din 1961 se foloseşte termenul de pilomatrixom (propus de Forbis şi Helwig), acesta fiind considerat mai corect din punct de vedere etimologic. Prezentăm în continuare două cazuri clinice de pilomatrixom şi discutăm principalele aspecte ale acestor tumori cutanate.

PREZENTAREA CAZURILOR

CAZUL 1

În aprilie 2010 s-a prezentat în Clinica de Chirurgie Orală şi Maxilo-Facială Iaşi o pacientă în vârstă de 55 ani, pentru o forma-

țiune tumorală localizată în regiunea temporală stângă, cu evoluție clinică de 2 ani (fig. 1). Examenul clinic a consemnat în regiunea temporală stângă (adiacent regiunii sprâncenare stângi) o tumoră rotundă, de circa 2 cm diametru, situată în planul subcutanat, cu tegumentul acoperitor congestionat, aderent la formațiune şi prezentând central o zonă ulcerată acoperită de o crustă hematică, formațiunea fiind uşor sensibilă la palpare. Formațiunea a fost extirpată în totalitate odată cu insula cutanată suprajacentă (fig. 2), defectul rezultat fiind refăcut printr-o plastie cu lambou cutanat bilobat din vecinătate (fig. 3,4). Examenul histopatologic definitiv a stabilit diagnosticul de certitudine de pilomatrixom (fig. 5,6), confirmând excizia în țesut sănătos. Controlul clinic efectuat după 10 luni de la intervenția chirurgicală nu a indicat semne de recidivă.

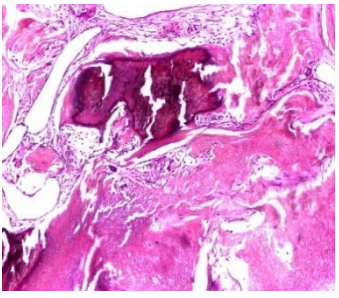

Fig. 6. Aspect microscopic de pilomatrixom (HE, obX4; arie de calcificare)

CAZUL 2

În februarie 2011 s-a internat în acelaşi serviciu o pacientă în vârstă de 51 ani prezentând o tumoră subcutanată la nivelul regiunii maseterine stângi, cu evoluție clinică de un an. Examenul clinic a relevat în jumătatea inferioară a regiunii maseterine stângi o tumoră ovoidală, de 4 cm/2 cm, dezvoltată subcutanat, de consistență fermă, nedureroasă, cu tegumentul suprajacent uşor congestionat şi aderent la formațiune (fig. 7). Diagnosticul clinic de probabilitate preoperator a fost de chist sebaceu. S-a efectuat extirparea formațiunii tumorale cu

sutură (fig. 8). Examenul histopatologic a stabilit diagnosticul de certitudine de pilomatrixom, cu evidențierea plajelor cu umbre celulare – „celule fantomă” (fig. 9).

DISCUȚII

Epiteliomul calcificat Malherbe (tricomicomul, pilomatricomul sau pilomatrixomul) este o tumoră benignă care se dezvoltă din celulele matriceale ale foliculului pilos, având o incidență de 1/800-1000 tumori cutanate, afectând predominant femeile (1, 2). A fost descris pentru prima dată de către Malherbe şi Chenantais în 1880 ca fiind o tumoră calcificată, cu originea în glandele sebacee. Ulterior, Forbis şi Helwig (citați de Chuang) au efectuat studii histochimice şi electronomicroscopice ale pilomatrixomului descoperind că originea celulară se află în teaca externă a rădăcinii foliculului pilos (3). Deşi pilomatrixomul poate apare la orice vârstă, s-a observat că este mai frecvent întâlnit în primele două decade de viață şi respectiv în decada a şasea (1). După naştere nu se mai formează noi foliculi piloşi iar în timpul pubertății doar o parte dintre foliculii piloşi existenți sunt activați. Dacă aceştia sunt localizați foarte profund, agenții de inducție a diferențierii nu vor acționa corespunzător asupra lor. Se crede că aceşti foliculi parțial diferențiați vor forma pilomatrixoamele (4).

Cele mai afectate regiuni de prezența pilomatrixoamelor sunt ariile capului şi gâtului, urmate de extremitățile superioare, trunchi şi extremitățile inferioare (5). Tabloul clinic obişnuit este cel al unei tumori nedureroase subcutanate sau intradermice, de consistență fermă şi creştere lentă în dimensiuni (luni sau ani), localizate la nivelul gâtului, regiunilor frontale, periorbitare şi preauriculare. În general, pilomatrixoamele sunt asimptomatice, dar uneori se asociază cu inflamarea şi ulcerarea tegumentului suprajacent (ca şi în cazurile prezentate aici); sunt însă mobile pe planurile subjacente.

Deşi au fost descrise în literatură şi localizări multiple asociate cu alte boli generale (distrofia miotonică Steinert, sindromul Gardner), pilomatrixomul apare adesea ca leziune unică (6,7,8).

Diagnosticul clinic preoperator este dificil de stabilit, pilomatrixomul fiind confundat de cele mai multe ori cu un chist sebaceu. Diagnosticul de probabilitate poate fi formulat atunci când o tumoră

subcutanată cu localizare în segmentele capului şi gâtului are consistenţa fermă spre dură, cu aspectul de „piatră faţetată”. Diagnosticul diferenţial se va face cu: chistul dermoid şi epidermoid, lipomul calcificat, chistul branhial, adenopatia calcificată, condromul, reacţiile de corp străin, hematomul calcificat, osteomul cutanat, hemangiomul sau tumora de glandă parotidă (9).

Investigaţiile imagistice (radiografiile simple, ultrasonografia, imagistica prin rezonanţa magnetică, tomografia computerizată) au valoare redusă în diagnosticarea pilomatrixoamelor. Tomografia computerizată, de exemplu, relevă doar situarea subcutanată a leziunii, delimitarea ei netă şi prezenţa calcificărilor în interior (1).

Caracteristicile histologice ale pilomatrixomului includ: leziune bine-delimitată alcătuită din celule bazale cu diferenţiere scuamoasă localizate la periferie şi celule „fantomă” dispuse spre centrul leziunii (10). Pot fi prezente şi depozite de calciu, osificări, reacţii de corp străin. Activitatea mitotică ridicată este o caracteristică a celulelor bazale dar nu indică malignitatea. Atipiile celulare, comportamentul agresiv local, invazia vasculară şi nodulii bazali infiltrativi sunt indicatorii pilomatrixomului malign („pilomatrix carcinoma”).

Puncţia-aspiraţie cu ac fin este utilizată ca o metodă de diagnostic preoperator, principala eroare diagnostică fiind rezultatul fals pozitiv pentru malignitate (11, 12). Dar, istoricul medical al afecţiunii coroborat cu prezenţa celulelor fantomă caracteristice, absenţa atipiilor celulare şi a mitozelor, prezenţa depozitelor de calciu şi a celulelor gigante multinucleate pot fi utile în stabilirea corectă a diagnosticului de pilomatrixom.

Întrucât regresia spontană a pilomatrixoamelor nu a fost niciodată observată, tratamentul standard constă din extirparea completă a leziunii. Se recomandă ca marginile extirpate din ţesut sănătos să fie de 1-2 cm, pentru a minimaliza riscul de recidivă locală. Uneori, datorită aderenţelor dermice ale tumorii, aceasta se extirpă împreună cu insula cutanată suprajacentă (similar cazurilor prezentate aici). Chirurgia Mohs poate asigura un control mai bun al marginilor exciziei. Suspiciunea de „pilomatrix carcinoma” apare în cazurile recidivelor locale multiple (13).

CONCLUZII

În cazul unei mase localizate superficial (subcutanat sau intradermic) la nivelul ariilor capului şi gâtului, de consistenţă fermă, cu textură de „piatră faţetată” trebuie avută în vedere şi entitatea denumită pilomatrixom.

Tratamentul de elecţie al pilomatrixomului este extirparea chirurgicală completă, cu margini largi de ţesut sănătos.

Mai curând sau mai târziu cele mai însemnate descoperiri pierd pecetatea personalităţii care le-a dat scânteia vieţii şi devin patrimoniu public : urmaşii le folosesc ca moştenire acumulată de nişte înaintaşi anonimi faţă de care uneori numai se mai simt îndatoraţi.

Constantin Ionescu-Mihăieşti

THE CENTENIAL OF THE DEPARTMENT OF MICROBIOLOGY IAŞI - TRIBUTE TO ANCESTORS • 1892-1913 Bacteriological investigations conducted in Iaşi's hospitals. • 1896 Up to date lectures featuring chapters on microbiology. • 1899-1911 The first interim of the Department. • 1 februarie 1912 Bacteriology Department *de iure et facto* : **Alexandru Slătineanu**. • 1938-39 Second intermediate period. • 1939-1942 Romanian inframicrobiology first started in Iaşi : **Ştefan S. Nicolau**. • 1942-1946 Third intermediate period. • 1946 The Bacteriology Department *redivivus* : Professor **Petru Condrea** • 1953 The Discipline of Virology : Professor **Mihai Duca**

În 1887 Victor Babeş era numit profesor la Facultatea de Medicină din Bucureşti unde a creat Institutul de Patologie şi Bacteriologie. *Regulamentul unificat al Facultăţilor de Medicină din Bucureşti şi Iaşi*, promulgat la 13 ianuarie 1897, deschidea perspectiva unei catedre de Bacteriologie şi la Iaşi, dar marginalizarea fostei capitale a Moldovei a descurajat atragerea personalităţii care să fondeze aici şcoală de bacteriologie. Ioan Cantacuzino, asistent al lui Ilia Mecinikov la Institutul Pasteur din Paris, venea la Iaşi în 1894 ca profesor de Morfologie al Facultăţii de Ştiinţe, dar după 2 ani îşi relua cercetările de bacteriologie şi imunologie în Franţa.

Investigaţii bacteriologice şi seroimunologice în spitale ieşene începeau din 1892 în laboratoare improvizate de profesori familiarizaţi cu aceste metode la Bucureşti, Viena, Budapesta ori Paris. Erau activi profesorii Emil Puşcariu în al său Institut Antirabic (1-5) ; Vasile Negel (6), Mihai Manicatide (7,8,9,10), Vasile Sion (11), Gheorghe Demetriade (12,13), Constantin Bacaloglu (14,15) la *Spitalul Sf. Spiridon* ; profesorul agregat Victor Imerwol la *Spitalul de copii Caritatea* (3,4,16,17) sau doctorul G. Sava-Goiu la *Spitalul pentru boli de ochi Frumoasa* (18). Studenţi, interni, asistenţi aveau acces pentru studii în aceste laboratoare. La Institutul Antirabic utilizau tehnici microbiologice Mircea Vesescu (2), absolvent din 1894, şi asistentul I. Lebell (4,5). În raportul de activitate din 1903 al profesorului Mihai Manicatide citim : *„…în laborator se lucrează cu microscopul nostru personal"* (19), iar în cel din 1097 : *„…am reuşit să facem în clinica infantilă un mic focar unde d-nii studenţi se pot instrui în observarea completă a bolnavilor cu cercetarea ştiinţifică,*

clinică şi bacteriologică" (20). Leon Şeptelici, absolvent din 1903, care lucrase în laboratorul clinicii infantile, conducea din 1911 pavilionul pentru izolarea bolnavilor tifici (21), în 1912 diagnostica bacteriologic şi serologic o complicaţie post-tifoidică la o bolnavă cu chist hidatic al ficatului (14), iar în 1913 publica analiza pneumocociilor diagnosticate în Spitalul Sf. Spiridon (22). Ioan Nimereanu, absolvent din 1905, preparator de Anatomie patologică al lui V. Negel (1901), asistent la clinica Dermato--Venerologică a lui G. Demetriade (1905--1908), apoi asistent, şef de lucrări şi conferenţiar la clinica Medicală a lui C. Bacaloglu, făcea examene bacteriologice (23) şi serodiagnosticul sifilisului (15).

Actualizarea cu capitole de microbiologie o găsim în 1896 în cursul de Clinică Medicală al lui Ludovic Russ jr. : *„...examine microscopice, bacteriologice..."* şi în cel de Patologie generală al lui Constantin Thiron : *„Vegetale parazite : ciuperci inferioare"* şi *„Bacterii infecţioase şi boalele pe care le produc"* (24).

Primul interimat al catedrei de Bacteriologie. La Iaşi Bacteriologia apare în orarul Facultăţii de Medicină abia în 1899. Cursul a fost asigurat 12 ani de profesori suplinitori, fără bază materială şi rar secondaţi de un asistent. S-au succedat V. Negel (1899-1900), V. Roşculeţ (1901-1908) şi E. Puşcariu (1908--1911). *Vasile Negel,* doctor în medicină la Paris în 1882, era profesor titular de Anatomie patologică şi şef de serviciu medical la Spitalul Sf. Spiridon. *Valeriu Roşculeţ* obţinuse doctoratul în medicină la Berlin (1890) şi la Iaşi (1894) cu aceeaşi teză de embriologie. În 1892 era asistent al lui Victor Babeş. Până în 1899 practicase medicina în diferite localităţi. La Iaşi a suplinit catedra de Histologie cât profesorul E. Puşcariu a fost secretar general în Ministerul Cultelor (1899-1901). A suplinit apoi 7 ani cursul de Bacteriologie, dar a lăsat o singură cercetare ştiinţifică în acest domeniu. I-a concurat, fără succes, pe Vasile Sion în 1901 şi pe G. Proca în 1903 la ocuparea catedrei de Igienă din Iaşi (25,26). *Emil Puşcariu,* cu studii medicale la Budapesta, Viena şi Paris, a fost primul şef de lucrări al lui Victor Babeş la Bucureşti. Era legat de mediul academic ieşean în calitate de membru corespondent naţional al Societăţii de Medici şi Naturalişti (27). În 1893 a fost numit profesor de histologie la Facultatea de Medicină şi a organizat Institutul Antirabic din Iaşi, cronologic al 4-lea din lume. Ca suplinitor al catedrei de Bacteriologie (1908-1911) a completat cursul teoretic cu lucrări practice.

Catedra de Bacteriologie *de iure et facto*. Alexandru Slătineanu şi şcolile sale. Deşi la 27 ianuarie 1904 Senatul universitar şi Colegiul Facultăţii de Medicină propuneau Ministerului Instrucţiunii Publice înfiinţarea catedrei de Bacteriologie (28), facţiuni rivale din Consiliul Profesoral au obstrucţionat mulţi ani titularizarea unui profesor (29). Abia la 1 februarie 1912 venea la Iaşi Alexandru Slătineanu, primul profesor titular de Bacteriologie din România. Fără mijloace pentru organizarea unui laborator, pe strada Săulescu 6, într-o încăpere din catedra de Chimie, doar cu o cretă şi o tablă de împrumut, dar cu vaste cunoştinţe şi charismă, Profesorul Slătineanu îşi începea cursul teoretic urmărit cu interes. În acelaşi an a fost mobilizat pentru combaterea holerei pe frontul din Bulgaria. Îşi relua activitatea la catedră în ianuarie 1914 confruntat cu reacţia ostilă a Decanului Nicolae Leon (30,31).

Dar cine era Alexandru Slătineanu şi ce a făcut el pentru Iaşi ? Descendent al unei vechi şi luminate familii de boieri din Ţara Românească, s-a născut la 5 ianuarie 1873 în Bucureşti. În 1892 a plecat să studieze medicina la Paris unde devenea în 1894 extern al spitalelor civile. Convins de importanţa chimiei şi biologiei pentru înţelegerea patologiei, a obţinut şi licenţa în ştiinţe naturale. Şi-a lărgit viziunea interferenţelor patologiei cu condiţia socială audiind, la

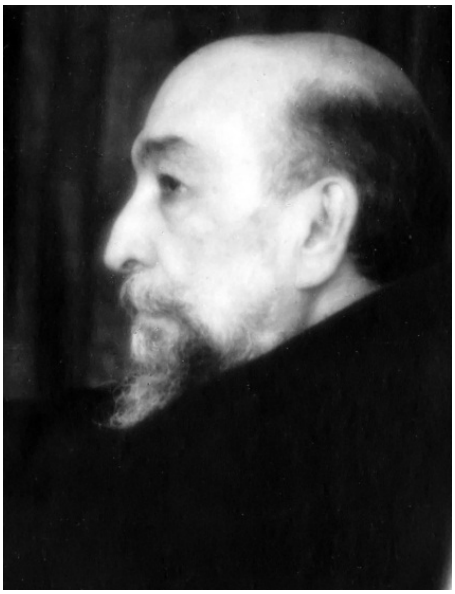
„Amatorul purta barbă şi semăna întrucâtva cu Anatole France. El se întorcea cu bucurie acasă unde regăsea obiectele de artă…”(66)

Combatantul (67,68)

Collège de France, cursul lui Théodule Ribot, care corela psihologia cu stările patologice, şi, la Facultatea de Drept, cursul lui Algave despre doctrinele sociale şi socialiste contemporane. Ioan Cantacuzino l-a introdus în Institutul Pasteur. Aici audia cursul de biochimie al lui Émille Duclaux şi de bacteriologie al lui Émille Roux, iar în laboratorul lui Mecinikov îşi elabora teza de doctorat *Septicémie expérimentale par le coccobacille de Pfeiffer. Essais d'immunisation*, cu care a obţinut în 1901 medalia de bronz a Facultăţii de medicină.

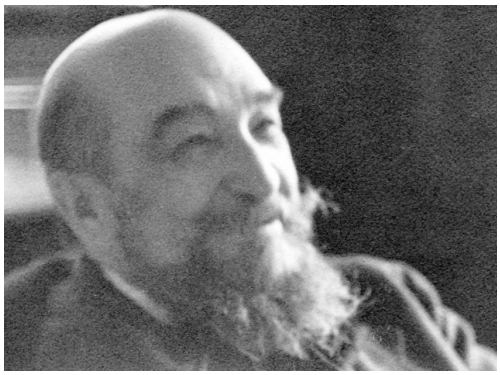
În momente de destindere frecventa, cu alţi tineri români, cafenenele Cluny, Voltaire sau Müller unde au atras simpatia socialiştilor francezi ca Jean Jaurès ori Georges Clemenceau. Vizita muzee, anticariate, cumpăra, cu competenţă de cunoscător, cărţi rare, gravuri, tablouri.

În 1902 a revenit în ţară cu mentorul şi prietenul său Ioan Cantacuzino, care fusese numit profesor la nou înfiinţata catedră de Medicină experimentală de la Facultatea de Medicină din Bucureşti. A acceptat propunerea lui Cantacuzino de a-i fi şef de lucrări şi a organiza laboratorul de cercetări. Bogat înzestrat, energic, organizator de excepţie, cu largă viziune medicală Alexandru Slătineanu nu s-a închis niciodată între pereţii laboratorului. A fost medic secundar în Serviciul pentru boli venerice (1902-1904), apoi în cel de Medicină internă (1904-1906) ale Spitalului Colentina, membru fondator şi colaborator al prestigioasei Revista Ştiinţelor Medicale (1905) şi al Reuniunii Biologice din Bucureşti (1906), prima filială străină a Societăţii Biologice din Paris. Din 1906 a condus spitalul şi sanatoriul pentru tuberculoşi Filaret, la a cărui înfiinţare contribuise. În 1907 a colaborat cu Profesorul Ioan Cantacuzino la reorganizarea serviciului sanitar şi a devenit inspector sanitar pentru epidemii (32). Cu această experienţă şi cu 47 studii de bacteriologie şi medicină experimentală publicate a ocupat catedra de Bacteriologie din Iaşi (33).



Savantul (67,68)

Revenit la Iaşi din Războiul Balcanic, a început, în aprilie 1914, să-şi organizeze laboratorul într-o casă închiriată pe strada Muzelor 18. De la Ministerul Instrucţiunii primise pentru instalare 10.000 lei – sumă cu care putea *„…organiza un laborator de campanie, dar nicidecum un laborator de învăţământ"* – şi un buget anual de 3.000 lei - faţă de 3.500 lei chiria localului (34). Cu bani personali şi donaţii, a realizat ce nu realizase Facultatea de Medicină în 25 de ani : la 22 noiembrie 1915 îşi începea cursul practic pentru studenţi (35), iar în Primul Război Mondial găzduia Laboratorul de Medicină experimentală al Profesorului Cantacuzino evacuat din Bucureşti (36, *vide infra*). După război şi-a dezvoltat laboratorul, care avea acum secţii de bacteriologie, imunologie, chimie fizică, biochimie, hematologie şi histopatologie. Îi solicitau servicii autorităţile medicale şi veterinare, militare şi civile, expertiza calitatea sticlăriei de laborator fabricată pentru prima dată în România. Contracte pentru prestări de servicii îi suplimentau bugetul. Profesorul Slătineanu făcea *avant la lettre* universitate antreprenorială



Spiritualul *„Conversaţia Amatorului era pasionantă. Totul, într-însul, te făcea să uiţi banalul vieţii cotidiene. Problemele de artă, filosofie, literatură şi economie politică alternau în mod natural cu dezbateri de ordine soc*

(37). De la creta şi tabla împrumutate în 1912, a lăsat în 1938, la pensionare, un laborator european modern. O sublinia urmaşul său la catedră, profesorul Stefan S. Nicolau : *„Acest laborator bogat şi admirabil dotat poate fi un subiect de mândrie al ştiinţei româneşti… e mai bogat ca cel al cărui titular am rămas încă în Institutul Pasteur din Paris. Aparate moderne şi extrem de costisitoare ; microscoapele* ***cele mai bune din lume*** *; instalaţie cu peste 25 mese cu faţă din lavă… ; material de sticlărie şi coloranţi în cantităţi mari… Preţuiesc între 10 şi 20.000.000 de lei averea laboratorului de Bacteriologie…Domnia–sa a făcut numeroase donaţii personale laboratorului : aparate scumpe, o bogată bibliotecă ştiinţifică, mobile, tablouri etc. Când se ştie că bugetul anual acordat de Ministerul Educaţiei Naţionale acestui laborator e sub 100.000 lei, nu rămâne decât de admirat opera creată de predecesorul meu"* (38).

În anii 1918-1920 conducea Direcţia Sănătăţii Publice din Ministerul de Interne. În 1919 îl suplinea pe Profesorul Ioan Cantacuzino aflat la Paris pentru tratativele de pace. În 1920 încheia, ca Director al Sănătăţii Publice, cu Epitropia Sf. Spiridon convenţia prin care organiza Spitalul Izolarea

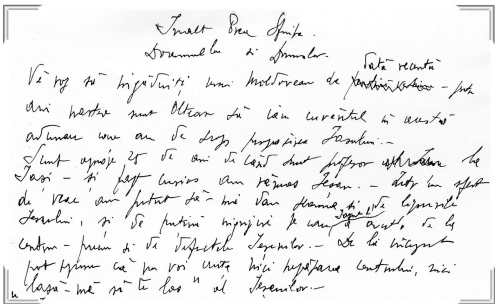
unde a pus bazele învăţământului de Boli Infecţioase la Iaşi (39).

Ca Rector al Universităţii Mihăilene (1923-26) şi membru al Senatului universitar (1928-29, 1933) a continuat lupta contra marginalizării învăţământului ieşean (40-42). Când Moldova rurală era măcinată de pelagră, propunea Ministrului Sănătăţii ridicarea etapizată, pe terenul de la Socola al Facultăţii de Medicină, a unei clinici medicale pentru „*studiul boalelor de nutriţie, dietetică etc.*" Specialistul capabil să organizeze asemenea clinică, Iuliu Niţulescu, tocmai revenise la Iaşi format la şcoala profesorului Mc Collum la Universitatea John Hopkins (40). Nu s-a făcut nimic. Prostie ? Indolenţă ? Rea-voinţă ? Problema a rezolvat-o cu improvizaţii făcute prin Institutul de Igienă şi Spitalul Izolarea. Dar facultatea a pierdut oportunitatea priorităţii şi ...terenul.

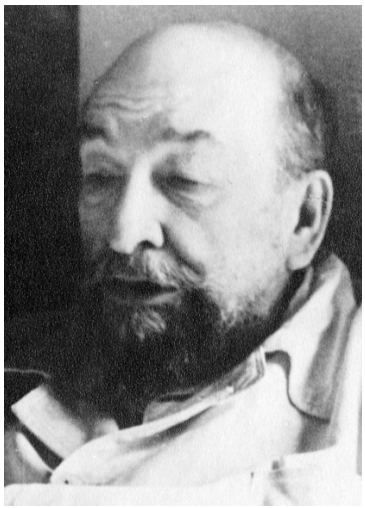
A fost primul Director al Institutului de Igienă din Iaşi (1930-1938), a condus Plasa sanitară de demonstraţie Tomeşti şi a organizat Centrul de tuberculoză şi Sanatoriul Erbiceni. Când Ioan Cantacuzino era Ministrul Sănătăţii l-a secondat în calitate de Secretar general al ministerului (1931-33) (32).

În anii 1926-27, 1930 şi 1933 era Preşedinte al Societăţii de Medici şi Naturalişti din Iaşi şi conducea Comitetul de redacţie al Revistei Medico-Chirurgicale. De-a lungul a 31 de ani a publicat în prestigioasele reviste Viaţa Românească şi Însemnări Ieşene cronică universitară (de la situaţia Facultăţii de Medicină la legenda autonomiei universitare), politică şi socială (de la analiza sindicalismului revoluţionar al lui George Sorel ori nedumeririle unui fost socialist la situaţia reală a ţărănimii române) sau ştiinţifică.

A polarizat în jurul său colaboratori cu care a făcut echipe de lucru competente şi unite. A promovat profesori la Iaşi colaboratori din Laboratorul de Medicină experimentală de la Bucureşti : pe Mihai Ciucă la catedra de Igienă şi Spitalul Izolarea (1922--35), pe C. Ionescu-Mihăieşti la Patologie generală (1925-30), Petru Gălăşescu la Anatomie patologică (1924-38), Ioan Bălteanu la Boli Infecţioase (1927-31), Patologie generală (1930-35), Igienă (1935-42), Ioan Nicolau la Patologie generală şi Medicină experimentală (1936-39), Clinica infantilă (1939-52). Prin ei a creat şcoli care au dus prestigiul Facultăţii de Medicină din Iaşi în ţară şi în lume. A fascinat tineri din facultăţile ieşene de medicină şi ştiinţe. Studenţii medicinişti Ioan Gheorghiu, cu care în 1914 începuse organizarea laboratorului, Ioan Alexa şi Constantin Bart, veniţi în 1920,



Din manuscrisul alocuţiunii Profesorului Slătineanu la adunarea din 1936 a notabilităţilor ieşene pentru propăşirea oraşului (prin bunăvoinţa D-nei Sandra Slătineanu – Sturdza)



Bolnavul (67,68)

i-au rămas discipoli devotaţi. Totdeauna, după 1920, a avut între preparatori şi un chimist. La catedra de Bacteriologie era vie tradiţia Medicinii experimentale: Ioan Gheorghiu studia heterografele de tumori maligne (prioritate bazată pe toleranţa imunologică, citată de J. Bordet, C. Arnouldi, O. Teutschländer şi R. Werner), iar profesorul Alexandru Moruzi făcea chirurgie experimentală. Dintre colaboratorii de la Institutul de Igienă şi de la Spitalul Izolarea remarcabili au fost viitorii profesori ai facultăţilor de medicină din Iaşi – Academicianul Iuliu Niţulescu la Fiziopatologie, Maria Sibi la Biochimie, Maria Franche la Boli Infecţioase, Anton Toma la Ftiziologie, Alexandrina Gaiginschi la Bacteriologie – ori Timişoara – Maria Zalman la Bacteriologie. Coralia Baldovin-Agapi a devenit şefa Secţiei de Streptococi din Institutul Cantacuzino unde şi-a continuat studiile începute la Iaşi.

Intransigenţa şi rectitudinea morală îi erau caracteristice. În 1918, când voci din Consiliul Facultăţii de Medicină îi acuzau de trădare pe profesorii Emanoil Riegler şi Francisc Rainer, apărătorii le-au fost Alexandru Slătineanu, Amza Jianu şi Constantin Parhon. Dar în marele colegiu consecvent, respingând orice compromis, a rămas doar Alexandru Slătineanu (43,44). În 1922 a semnat alături de Victor Babeş, Ioan Cantacuzino ş.a. protestul Asociaţiei generale a Medicilor contra murdarei lucrături politice prin care se urmărea îndepărtarea profesorului Iuliu Moldovan din postul de inspector general sanitar (45).

La catedra de Bacteriologie lucrau voluntari pentru specializarea în medicina de laborator. La Institutul de Igienă organiza cursuri de malariologie, igienă şi medicină preventivă, medicină şcolară, formarea surorilor de ocrotire, cursuri de igienă pentru învăţători.

Alexandru Slătineanu a venit şi a luptat pentru Iaşi până s-a stins din viaţă la 27 noiembrie 1939 cu crezul său *ubi patria ibi bene*. Prea mulţi ieşeni îşi părăseau atunci vatra din convingerea meschină că *ubi bene ibi patria*.

Al doilea interimat. Profesorul *Ioan Bălteanu* a suplinit catedra de Bacteriologie de la pensionarea Profesorului Slătineanu

Requiem aeternam dona eis Domine, et lux perpetua luceat eis (novembris Anno Domini 1939) (67,68)

(1938) până la numirea profesorului Ştefan S. Nicolau (1939). Era titular la Direcţia Institutului de Igienă şi a Spitalului Izolarea. A respectat spiritul şi unitatea acestor şcoli.

Inframicrobiologia* **românească la Iaşi a început, 1939-1942. Ştefan S. Nicolau** (Bucureşti 1896 – Bucureşti 1967) prelua Catedra de Bacteriologie prin Înaltul Decret Regal Nr. 2402 din 7 iunie 1939 *„pe baza legii pentru autorizarea Ministerului Educaţiei Naţionale de a ocupa prin numire directă această catedră".* În 1920 devenise doctor al Facultăţii de Medicină din Cluj, unde a fost remarcat de profesorii Iuliu Moldovan şi Constantin Levaditi.

Inframicrobiologie era sinonimul conceput şi preferat de Ştefan S. Nicolau pentru virologie

Între 1921 şi 1939 a lucrat la Institutul Pasteur din Paris şi la Institutul Naţional pentru Cercetări Medicale din Londra în laboratoarele profesorilor C. Levaditi şi I.A. Golloway. L-au atras mai ales cercetările privind variate viroze şi patogenia acestora. Încă din acea perioadă are priorităţi recunoscute : conceptele de septinevrită (propagarea virusurilor neurotrope prin nervi periferici) şi sincronofilaxie (interferenţa virală), efectul fotodinamic al unor coloranţi asupra virusurilor. Şi-a publicat studiile în prestigioase reviste franceze, engleze şi româneşti. A redactat capitole în *Traité de Microbiologie* al lui Nattan Laurier (1927). A editat monografii ca *Borna Disease and Enzootic Encephalo-Myielitis of Sheep and Cattle* – S. Nicolau and I.A. Golloway (1928). A devenit Doctor în ştiinţe naturale la Sorbona, a fost şef de laborator la Institutul Pasteur şi laureat al Academiei de Ştiinţe din Paris cu premiile *Bellion* (1925), *Bréant* (1930) şi *Montyon* (1935) (43).

La Iaşi, impresionat de realizările predecesorului său, a numit catedra preluată *Institutul de Bacteriologie Dr. Alexandru Slătineanu* şi în faţa localului a pus, cu ceremonial deosebit, bustul în bronz al Profesorului Slătineanu (44).

Cu excelenta dotare la dispoziţie, şi-a continuat cercetările de la Paris. A publicat 11 studii şi a comunicat 8 privitoare la : septinevrita rabică, ultravirusuri, morfogeneza incluziilor în febra galbenă, absenţa neurotropismului la unele tulpini de virus herpetic izolate la Iaşi, herpesul recidivant. Între colaboratori reţinem studentul Radu Portocală şi preparatoarea Artemiza Moţoc. Radu Portocală, student medicinist în Bucureşti, şi-a lucrat la Iaşi, îndrumat de Ştefan S. Nicolau, teza de doctorat *Studiul experimental, histopatologic şi morfologic asupra inframicrobului herpetic,* laureată în 1942 cu premiul *Dr. Gălăşescu* al Facultăţii de Medicină din Iaşi (45,46).

Preda studenţilor cursurile despre virusuri şi conducea lucrările practice privind diagnosticul turbării. Bacteriologia o lăsase pe seama şefului de lucrări, doctorul Constantin Bart, care avea o experinţă de peste 20 de ani în acest domeniu (47). Organizase în 1940 un curs postuniversitar de Microbiologie şi Patologie experimentală. Maria Golăescu, asistentă la Clinica Chirurgicală a profesorului Alexandru Cosăcescu, l-a absolvit în 1942 cu lucrarea *Morfologia corpusculilor elementari vaccinali în ţesuturile animalelor infectate* (46). Aşa a păşit Maria Golăescu spre cariera de profesor de Boli Infecţioase la Spitalul Colentina din Bucureşti.

În septembrie 1942 profesorul Stefan S. Nicolau a plecat la Facultatea de Medicină din Bucureşti unde a pus bazele catedrei de Inframicrobiologie. Relua totul de la capăt. Primii alături i-au fost Radu Portocală (*vide supra*) şi preparatoarea sa de la Iaşi Artemiza Moţoc, care obţinuse de la Ministerul Educaţiei Naţionale şi Cultelor transferul „*în post vacant la catedra de Bacteriologie (Inframicrobiologie) de la Facultatea de Medicină din Bucureşti*" (48). Acelaşi Minister aprobase profesorului Nicolau să împrumute de la Institutul de

Bacteriologie Alexandru Slătineanu din Iaşi un microscop cu fluorescenţă Reichert, un microscop binocular Leitz cu toate anexele, un microtom Spencer, cutii pentru preparate microscopice, cărţi – adresa Nr. 244.888 din 16 noiembrie 1942 cu menţiunea : *„se obligă a restitui aceste aparate, cărţi şi materiale când Ministerul o va cere”*, încuviinţată de Consiliul Profesoral al Facultăţii de Medicină din Iaşi în şedinţa din 7 decembrie 1942 (49,50).

Al treilea interimat a fost asigurat de patru profesori. Episodică a fost trecerea profesorilor, de Anatomie patologică, *Constantin Vasilescu* (octombrie 1942) şi de Parazitologie, *Virgil Niţulescu* (noiembrie 1942). Gheorghe Năstase, profesor de Dermato--Venerologie, a suplinit catedra între ianuarie 1943 şi noiembrie 1945, perioada grea a refugiului facultăţii la Alba Iulia şi revenirii în Iaşii devastaţi de trecerea frontului. Ioan Nicolau, cu experienţa unui fost şef de secţie în Institutul Cantacuzino la Bucureşti, a urmat între decembrie 1945 şi august 1946. Preocupat de viitorul şcolii ieşene de Bacteriologie căuta studenţi talentaţi şi cu pasiune pentru munca de laborator.

Catedra de Bacteriologie *redivivus* : Petru Condrea şi elevii săi. Petru Condrea (Bârlad 1888 - Bucureşti 1967) a venit titular al catedrei de Bacteriologie la 1 noiembrie 1946. Era doctor în medicină de la Bucureşti din 1915. Dobândise ample cunoştinţe de patologie generală, anatomo- şi histopatologie, medicină experimentală, microbiologie şi epidemiologie în şcolile profesorilor Victor Babeş (preparator onorific 1911-13), I. Bălăcescu (şef de laborator la Clinica de Chirurgie infantilă 1919), I. Nanu – Muscel (prozector şi şef al laboratorului de histopatologie şi bacteriologie la Clinica I-a Medicală 1920), Ioan Cantacuzino (preparator 1914--1918, asistent din 1921, şef de lucrări 1925--28, conferenţiar de Patologie comparată din 1929). Se adăuga experienţa anilor medicinei de campanie din Războiul Balcanic şi primul Război Mondial. Au urmat studiile aprofundate la Berlin (1922 : Institutul de Anatomie Patologică) şi Paris (1925-26 : Institutul Pasteur, Institutul Medico-Legal). De la înfiinţarea Institutului de seruri şi vaccinuri *Dr. I. Cantacuzino*, în 1921, a participat la cercetarea ştiinţifică şi producţie ca şef de laborator, apoi Director de secţie. A reprezentat institutul cu diferite ocazii la Zagreb (1927), Praga (1938), Paris (1939) (51). Cu Iaşii avea contacte vechi. În 1918-19 căpitanul medic Condrea Petru era mobilizat, alături de medicii colonel Slătineanu Al., locotent-colonel Ciucă Mihai şi căpitanii veterinar Ciucă Al., medic Nicolau Ioan şi medic Gheorghiu Ioan, în laboratorul de Medicină experimentală : *„… la ordinile M.C.G. pentru a prepara serurile şi vaccinurile necesare în situaţia actuală”* (36,*vide supra*).

Ca profesor titular de Bacteriologie şi Inframicrobiologie, la Iaşi, Petru Condrea a continuat studiile pentru ameliorarea randamentului producţiei de anatoxine şi antitoxine, a contribuit esenţial la studiul şi combaterea epidemiei de tularemie din Moldova anilor 1948-49, a organizat o filială a Institutului Cantacuzino, a refăcut şcoala de microbiologie. Vechii colaboratori ai Profesorului Slătineanu nu mai erau : profesorul agregat Ioan Gheorghiu fusese epurat din universitate chiar când era mobilizat în război (1945) şi arestat în 1950 (52,53,54), conferenţiarul Ioan Alexa îndepărtat în 1945 prin „avansare” în centrala Ministerului Sănătăţii, şeful de lucrări Constantin Bart, cu postul comprimat la 1 octombrie 1947, se retrăsese la Alba Iulia urmat de „dosarul de cadre”. Rămăsese doar asistenta Alexandrina Gaiginschi. Profesorul Condrea a polarizat studenţi şi absolvenţi. În primii şapte ani îi trecuseră prin laboratoare 21 preparatori. Aparent izolat, dar cunoscător de talente şi caractere, impunea

disciplină şi scrupulozitate. Când în 1953 o normare rigidă i-a redus numărul colaboratorilor la şase, profesorul Condrea formase deja mulţi microbiologi de perspectivă. Pe unii i-a reţinut la catedră (viitorii profesori Alexandrina Gaiginschi, Grigore Teodorovici, Eugenia Duca, Natalia Stavri, Sofia Timoşca) sau i-a orientat spre Institutul Cantacuzino la Bucureşti (Alexandru Petrovici, Aurica Cheptea) ori Iaşi (Ioan Pencea, Nicolae Laşcu, Marcus Lazăr), alţii au ajuns şefi ai unor laboratoare de microbiologie (Constanţa Cniş-Dragomir, Maria Olănescu-Antonescu, Carol Feldi). Pentru studenţii medicinişti şi pentru formarea specialiştilor bacteriologi a editat apreciate manuale la redactarea cărora selectase cei mai competenţi colaboratori. La solicitarea Ministerului Chimiei, între 1 februarie 1954 şi 31 ianuarie 1955, catedra a organizat cursul de calificare microbiologică personalului Fabricii de Antibiotice Iaşi, care în decembrie 1955 producea prima şarjă de penicilină românească. Cursuri de perfecţionare au fost apoi solicitate periodic.

Alexandrina Gaiginschi (Iaşi 1904 – Iaşi 2001) era formată în şcoala Profesorului Slătineanu la Institutul de Igienă din Iaşi. Între 1933-36 aprofundase studiul microbacteriilor în laboratoarele profesorilor Albert Calmette şi Alfred Bouquet la Institutul Pasteur din Paris. Era medic primar de laborator când a fost numită asistent al catedrei de Bacteriologie la 1 ianuarie 1939 (55). Profesorul Condrea i-a preţuit competenţa, calităţile umane şi morale promovând-o şef de lucrări (1949) şi conferenţiar (1952). Devenea profesor titular în 1963. A fost un cercetător pasionat – la catedră şi ca şef de secţie la Institutul de Igienă din Iaşi (1941-1951), şef de lucrări la Institutul de Ftiziologie (1951-56), şef de sector la Institutul de Cercetări Medicale al Academiei Române filiala Iaşi (1957 până la pensionarea din 1969) – al fiziologiei şi variabilităţii bacililor tuberculozei, al bacteriilor cu perete defectiv. Studiile sale sunt actuale şi în prezent (56). A format generaţii de bacteriologi dintre care mulţi au ajuns cunoscuţi profesori la Universităţile de Medicină din Iaşi şi Târgu Mureş.

Grigore Teodorovici (Faraoanele, Vrancea 1922 – Iaşi 1992). Caracterizarea făcută de exigentul profesor Condrea la 7 ianuarie 1953 spune multe: *„…numit în postul de preparator în mai 1946 după recomandarea Tov.Prof.Dr. Ion Nicolau,* [care] *mi-a făcut aprecieri elogioase asupra activităţii Tov. Gr. Teodorovici la acea dată. …relevându-se ca cel mai valoros dintre asistenţii laboratorului, a fost propus de noi şi numit ca şef de lucrări în 1949 în care calitate a funcţionat până la recenta restructurare a cadrelor didactice când a fost încadrat ca asistent"* (57). Reîncadrat şef de lucrări la 1 octombrie 1957, prelua în 1959 catedra de Epidemiologie unde a ctitorit noua şcoală ieşeană de epidemiologie. În şcoala profesorului Condrea Grigore Teodorovici şi-a însuşit înalte competenţe de bacteriolog, pe care le-a dovedit ca şef al Secţiei de Microbiologie din Institutul de Cercetări Chimico-Farmaceutice, filiala Iaşi (1957-59), de consilier pentru probleme de microbiologie al Fabricii de antibiotice din Iaşi ca şi în viitoarea carieră de epidemiolog. Anchetele sale epidemiologice, în lungul şi în latul Moldovei, erau lecţii de epidemiologie, de microbiologie şi de patologie infecţioasă.

Omagiem în profesorul Grigore Teodorovici nu numai pe dascălul formator de competenţe şi caractere, ci şi pe cel care 32 de ani a fost sufletul Revistei Medico-Chirurgicale din Iaşi.

Eugenia Duca (Iaşi 1923) rămâne în istoria bacteriologiei prin descoperirea capacităţii nefritogene a *Streptococcus zooepidemicus*, care a determinat în 1968, la Piatra Neamţ, o epidemie de angine transmisă

prin lapte de la vaci cu mastită (58). Abia în 1982 *S. zooepidemicus* a fost înscris pe lista agenţilor transmişi prin lapte şi derivate (59), iar capacitatea nefritogenă i-a fost confirmată de Barnham et al. în 1983 (60) şi de Francis et al. în 1993 (61). Din 1984 prioritatea ieşeană a descoperirii nefritogenităţii acestui streptococ de grup C este citată în repetate ediţii ale marilor tratate ca *Topley and Wilson's Principles of Microbiology and Microbial Infections, Harrison's Principles of Internal Medicine, Oxford Textbook of Medicine* etc.

Şcoala de virologie : Mihai Duca, 1953. În iunie 1948 profesorul Condrea cerea : *„…înfiinţarea unei conferinţe de* ***Inframicrobiologie şi Morfologie Bacteriană*** *anexată catedrei de Bacteriologie"* (62). **Mihai Duca** (Ripiceni 1922 - Iaşi 1998) ocupa acea conferinţă din 15 septembrie 1953. În anii 1950-53, ca tânăr şef de lucrări cu delegaţie de conferenţiar la catedra de Igienă generală, îşi însuşise virologia experimentală în laboratorul de Virologie al Institutului de Igienă din Iaşi unde doctorul Nicolae Constantinescu cerceta turbarea, chorio-meningita limfocitară şi rubeola. În scurt timp a organizat laboratorul de Virologie al catedrei de Microbiologie, a format o echipă de lucru cu care a început cercetări pentru prepararea de vaccinuri virale inactivate cu ioni de argint şi a elaborat, sub îndrumarea Academicianului Ştefan S. Nicolau, dizertaţia *Virusul Coxsackie şi coxsackiozele. Studiu clinic, epidemiologic şi virusologic* susţinută în 1960 pentru titlul de candidat în ştiinţe medicale.

După stagii, în anii 1959-60, la Institutul Pasteur din Paris, *Central Public Health Laboratory* din Londra şi *Staatens Bacteriologiska Laboratorium* din Stockolm, urmate de schimburi de experienţă la Moscova şi Leningrad, a organizat la Iaşi un modern laborator recunoscut ca for metodologic în *World List of Virus Laboratories* (O.M.S., Geneva 1964). A studiat mixovirusurile, adenovirusurile, arbovirusurile şi standardizarea diagnosticului de laborator al virozelor corespunzătoare. Mai mult de 35 de ani a cercetat ecologia virusurilor gripale, a definit *gradientul stratificat* de imunitate antigripală şi relaţia sa cu variaţia naturală a acestor virusuri. Ca recunoaştere a valorii acestor cercetări, Organizaţia Mondială a Sănătăţii i-a acreditat laboratorul ca Centru National pentru studiul şi supravegherea gripei, iar profesorul Mihai Duca a fost numit expert pentru boli virale începând din 1968 şi a lucrat ca ofiţer medical superior în Serviciul de Boli virale din Centrala O.M.S. de la Geneva (1971-73). A fost consultant cu drept de vot al *International Committee on Nomenclature of Viruses*.

Cu prestigiu şi talent organizatoric, profesorul Duca a fost mulţi ani în conducerea Universităţii de Medicină şi Farmacie din Iaşi : Decan al Facultăţii de Igienă (1952-53), prorector pentru activitatea ştiinţifică (1954-67), Rector (1967-71).

FORMULATION BY DESIGN OF EXPERIMENTS OF IMMEDIATE RELEASE TABLETS WITH METFORMIN HYDROCHLORIDE AND GLIBENCLAMIDE (Abstract): The present investigation was based on the latest quality by design principles, using the design of experiments technique. The aim was to attain an immediate release formulation of metformin hydrochloride and glibenclamide and to optimize the delivery of these two different antidiabetic agents within a single-tablet combination. **Materials and methods**: Due to the poor flow properties of metformin hydrochloride, in order to attain the dose uniformity, a wet granulation based manufacturing process was used. The prepared tablets were evaluated for the release of metformin hydrochloride and glibenclamide using validated HPLC methods. The similarity factor was calculated, taking into consideration as reference profile the mean *in vitro* dissolution data of Glucovance®. The formulation process was undertaken using a reproducible DoE generated model, attained by the variation of each of the formulation factors on two levels, followed by the filling of the data resulted from the analytical testing of the tablets. **Results**: The model was fitted using Partial Least Squares method. For the assessment of the level of fitting, Q2, R2 and Anova tests were performed. The desired drug release pattern can be achieved by using a proper percent of superdesintegrant, by reducing the filler and by the presence of extragranulary added binder. **Conclusion**: The results have shown that the experimental responses match the statistical generated model and that the investigation is reproducible. **Key words**: METFORMIN HYDROCHLORIDE, GLIBENCLAMIDE, FORMULATION, DESIGN OF EXPERIMENTS, TABLETS

Prin mecanisme de acţiune complementare, glibenclamida şi metforminul (agenţi diferiţi din punct de vedere chimic) s-au dovedit ideali pentru administrarea concomitentă la pacienţii diabetici într-o formă farmaceutică monodoză de comprimate.

În timp ce sulfonilureele acţionează prin stimularea sintezei de insulină de către pancreas, biguanidele acţionează prin amplificarea metabolismului glucozei, reducând rezistenţa la insulină şi gluconeogeneza hepatică (1).

Formulările efectuate în cadrul acestui studiu corespund unor forme solide orale care conţin 500 mg clorhidrat de metformin şi 2,5 mg glibenclamid pe comprimat.

Obiectivul studiului a constat în optimizarea formulării la scară de laborator a comprimatelor cu eliberare imediată care conţin asocierea metformin/glibenclamid, în raport de 500 mg/2,5 mg.

Cele două substanţe sunt foarte diferite în ceea ce priveşte solubilitatea în apă: clorhidratul de metformin este uşor solubil

(clasa BCS III, care cuprinde substanţele cu permeabilitate mică şi solubilitate crescută), iar glibenclamida este greu solubilă în apă şi prezintă şi un uşor caracter acid (clasa BCS II, care cuprinde substanţele cu permeabilitate mare şi solubilitate scăzută). În consecinţă, obiectivul acestui studiu constă în obţinerea unor comprimate prin combinarea acestor două substanţe, care să asigure eliberarea şi dizolvarea glibenclamidei în timp util manifestării acţiunii terapeutice.

MATERIAL ŞI METODE

Substanţele medicamentoase şi excipienţii (tab. I) folosiţi în formularea comprimatelor corespund normelor de calitate pentru substanţele de uz farmaceutic prevăzute de *Farmacopeea Europeană 6.0*. (3).

Formula generală de experimentare (tab. II) prezintă două variante, în funcţie de masa comprimatului (600 mg sau 620 mg), proporţia excipienţilor fiind aceeaşi în cazul liantului, dezagregantului şi lubrifiantului. Reglarea masei comprimatului se realizează prin modificarea procentului de excipient majoritar (diluantul).

Dispozitivele utilizate: omogenizator în V de 60 L, maşină de comprimat Kilian S250 cu un poanson de diametru ? 12 mm biconvex, Logan HDT 300 Hardtester, tambur rotativ Electrolab EF-2 friabilator, tester de dizolvare Electrolab TDT-08L, HPLC Surveyor Plus.

TABELUL I

Substanţele active şi excipienţii utilizaţi în formulare

Substanţe active şi excipienţi	Producător
Clorhidrat de metformin	Microsin Romania
Glibenclamidă micronizată	USV India
Glibenclamidă nemicronizată	Cadila India
Celuloză microcristalină (Vivapur® Type 101)	JRS Pharma Germania
Lactitol monohidrat granulat	Purac Biochem Olanda
Croscarmeloză sodică (Vivasol®)	JRS Pharma Germania
Polivinilpirolidonă (Plasdone® S-630)	ISP, Elveţia
Stearat de magneziu (Kemilub® EM-F-V)	UNDESA, Spania

Etapele procesului de preparare prevăd granularea umedă a clorhidratului de metformin, urmată de dispersarea geometrică a glibenclamidului în granulat. La amestecul obţinut se adaugă diluantul, liantul (extragranular) şi dezagregantul. După omogenizarea pulberilor, urmează lubrifierea cu stearat de magneziu şi comprimarea.

Planurile de experimente sunt utilizate în prezent pentru majoritatea proceselor de optimizare. Ideea de bază constă în

TABELUL II

Compoziţia calitativă şi cantitativă a formulei generale de experimentare

Formula generală de experimentare		Metformin clorhidrat	Glibenclamidă micronizată/ nemicronizată	Copovidonă intragranular	Celuloză microcristalină/ Lactitol monohidrat	Copovidonă extragranular	Croscarmeloză sodică	Stearat de magneziu	Total
Var. I	%	83.333	0.4166	3	5.45-10.45	0-3	2-4	0.8	100
Var. II		80.645	0.4032	3	8.15-13.15	0-3	2-4	0.8	100
Var. I	mg/ comprimat	500	2.5	18	32.7-62.7	0-18	12-54	4.8	600
Var. II		500	2.5	18.6	50.536 - 81.536	0-18.6	4.8	4.96	620

definirea unui plan experimental în care toţi factorii variază sistematic. Aspectul cel mai important al acestei metodologii se referă la furnizarea unui cadru matematic riguros de ecuaţii liniare sau polinomiale.

Analiza rezultatelor permite identificarea condiţiilor optime de desfăşurare a experimentelor, depistarea influenţei factorilor de formulare, precum şi prezenţa interacţiunilor şi a sinergismelor (2).

Planul de experimentare s-a realizat cu ajutorul programului statistic Modde 9.0 (Umetrics, Suedia).

Pentru experimentare s-a ales un plan factorial cu cinci factori şi două nivele de variaţie.

Variabilele independente (tab. III) : tipul de diluant (Celuloză microcristalină 101/ Lactitol monohidrat) – variabilă calitativă, procentul de dezagregant (2%/4%) – variabilă cantitativă multilevel, masa comprimatului (600 mg/620 mg)–variabilă cantitativă multilevel, procentul de liant extragranular (0%/3%)–variabilă cantitativă multilevel, sortul de glibenclamidă utilizat (micronizată/nemicronizată) – variabilă calitativă.

Variabilele dependente, respectiv proprietăţile farmacotehnice ale comprimatelor (tab. IV), sunt : friabilitatea (intervalul de variaţie : 0-1 %), rezistenţa mecanică (intervalul de variaţie : 50-120 N), dezagregarea (intervalul de variaţie : 0-240 sec), testul de dizolvare *in vitro* cu evaluarea factorului de similaritate f2 (intervalul de variaţie : 30-100%, valoarea ţintă 60%) (F2G, F2M).

Determinările analitice pentru parametrii friabilitate, rezistenţă mecanică, dezagregare şi pentru testul de dizolvare au respectat prevederile Farmacopeei Europene 6.0 (3).

Friabilitatea comprimatelor neacoperite reprezintă fenomenul prin care suprafaţa comprimatelor se deteriorează sau prezintă semne de abraziune sau de rupere, sub acţiunea şocurilor mecanice şi a frecărilor.

TABELUL III

Variabilele independente şi nivelurile corespunzătoare de variaţie

Variabilă independentă	Abreviere	Unitate de măsură	Tip	Nivele de variaţie

Fig. 1. Matricea ce cuprinde condiţiile şi rezultatele experimentării

Testarea friabilităţii reprezintă media a 20 determinări consecutive.

Rezistenţa mecanică a comprimatelor trebuie să fie suficientă pentru a permite procesarea, ambalarea şi utilizarea comprimatelor. Aceasta reprezintă media a 10 determinări consecutive.

Dezagregarea comprimatelor reprezintă capacitatea acestora de a se dezagrega în mediu apos, în timpul prevăzut şi în condiţii bine definite. Testul s-a efectuat cu o limită de dezagregare pentru comprimate neacoperite de maxim 15 minute.

Condiţiile pentru testul de dizolvare *in vitro* au fost următoarele: aparatul nr. 2 (palete), mediu de dizolvare (soluţie tampon pH 7.4 + polisorbat 80 0.03 %), temperatura mediului de dizolvare $37 \pm 0{,}5°C$, viteza de agitare 100 rpm, timpii de prelevare a probelor: 15, 30, 45, 60 min, metode HPLC validate pentru dozarea celor două substanţe active.

Evaluarea factorului de similaritate f2 s-a efectuat pentru a compara curbele de dizolvare a formulelor studiate cu cea corespunzătoare medicamentului de referinţă. Factorul de similaritate f2 defineşte distanţa dintre două curbe de dizolvare şi se calculează folosind următoarea formulă:

$$f_2 = 50 \cdot \log\left\{\left[1+\frac{\sum_{i=1}^{P}(\mu_{ri}-\mu_{ti})^2}{P}\right]^{-\frac{1}{2}} \cdot 100\right\}$$

Unde :

- P = numărul de determinări
- m_{ri} şi m_{ti} = media rezultatelor determinărilor la timpul t_i , pentru medicamentul de referinţă şi pentru formulele testate (4).

Valoarea optimă a factorului de similaritate f2 pentru profilul unui comprimat nefilmat este de 60%. Aceasta permite ca, în momentul filmării comprimatelor, curba de dizolvare să fie cât mai apropiată celei corespunzătoare medicamentului de referinţă (Glucovance®), adică Î100%.

Fig. 6. Rezultatele testului Anova pentru parametrul F2G

Rezultatele obţinute prin analiza parametrilor friabilitate, rezistenţă mecanică, dezagregare, similaritate profil de dizolvare metformin, similaritate profil de dizolvare glibenclamidă au fost interpretate statistic.

Fitarea datelor

Analiza regresională (fitarea datelor) reprezintă o metodă statistică de identificare

a unei relaţii cantitative între variabilele independente (factori) şi variabilele dependente (răspunsuri). Aceasta s-a realizat utillizând metoda Partial Least Squares (PLS), cu o marjă de încredere de 95 % pentru toate răspunsurile obţinute.

Coeficientul regresiei multiple (R^2) şi validitatea ecuaţiei de regresie (Q^2) sunt parametri statistici care evaluează gradul de fitare - corespondenţă cu modelul regresional ales, respectiv al ecuaţiei polinomiale cu datele experimentale. O valoare cât mai apropiată de 1 pentru aceşti parametri indică un model experimental bine ales.

Calitatea fitării a fost evaluată prin determinarea parametrilor statistici R^2 şi Q^2, prin analiza varianţei (testul Anova) şi prin trasarea curbelor de dependenţă.

Analiza varianţei (testul Anova) stabileşte dacă variaţia rezultatelor se datorează modificării factorilor de formulare sau dacă reprezintă o variaţie naturală a fenomenului.

Influenţa factorilor de formulare asupra parametrilor friabilitate, rezistenţă mecanică, dezagregare, factor de similaritate profil de dizolvare (glibenclamidă), factor de similaritate profil de dizolvare (metformin) a fost investigată cu ajutorul diagramelor Coefficient Plot, generate de programul statistic folosit în cadrul cercetării.

REZULTATE

Prin variaţia factorilor de formulare pe cele 2 nivele corspunzătoare au rezultat cele 36 de experimentări cu următoarele rezultate - matricea de experimentare (fig. 1).

Friabilitatea comprimatelor s-a situat în intevalul 0,41-0,97%, sub limita maximă

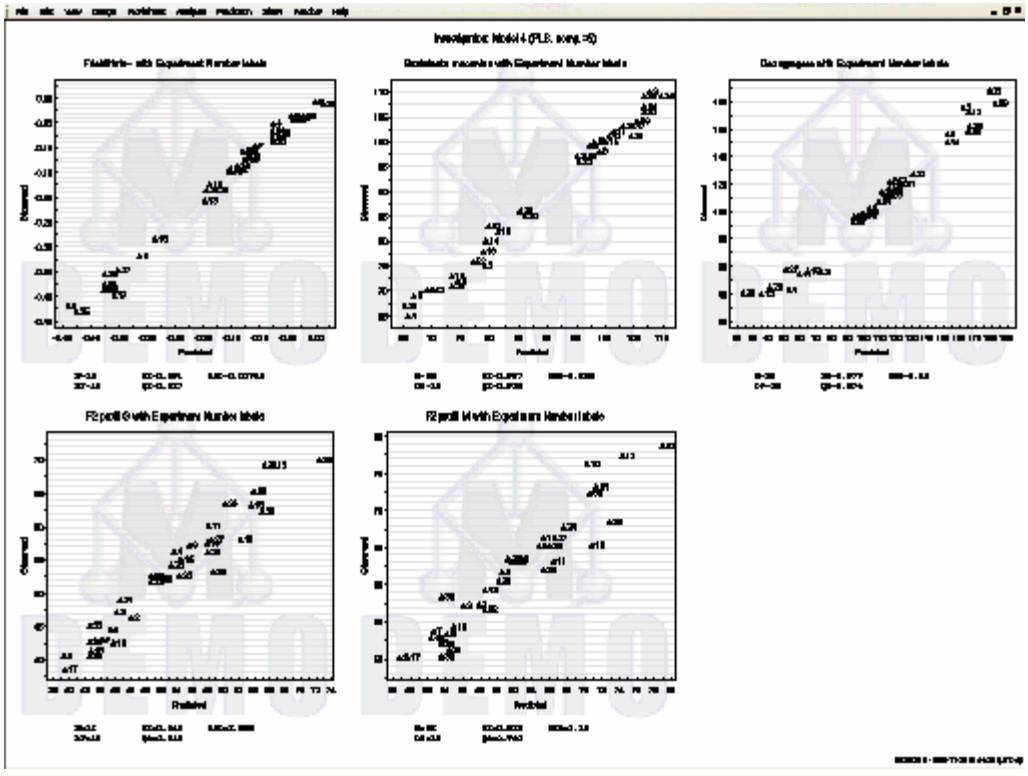

Fig. 7. Curbele reziduale ale răspunsurilor observate în funcţie de răspunsurile estimate pentru parametrii friabilitate, rezistenţă mecanică, dezagregare, factor de similaritate profil de dizolvare (glibenclamidă), factor de similaritate profil de dizolvare (metformin)

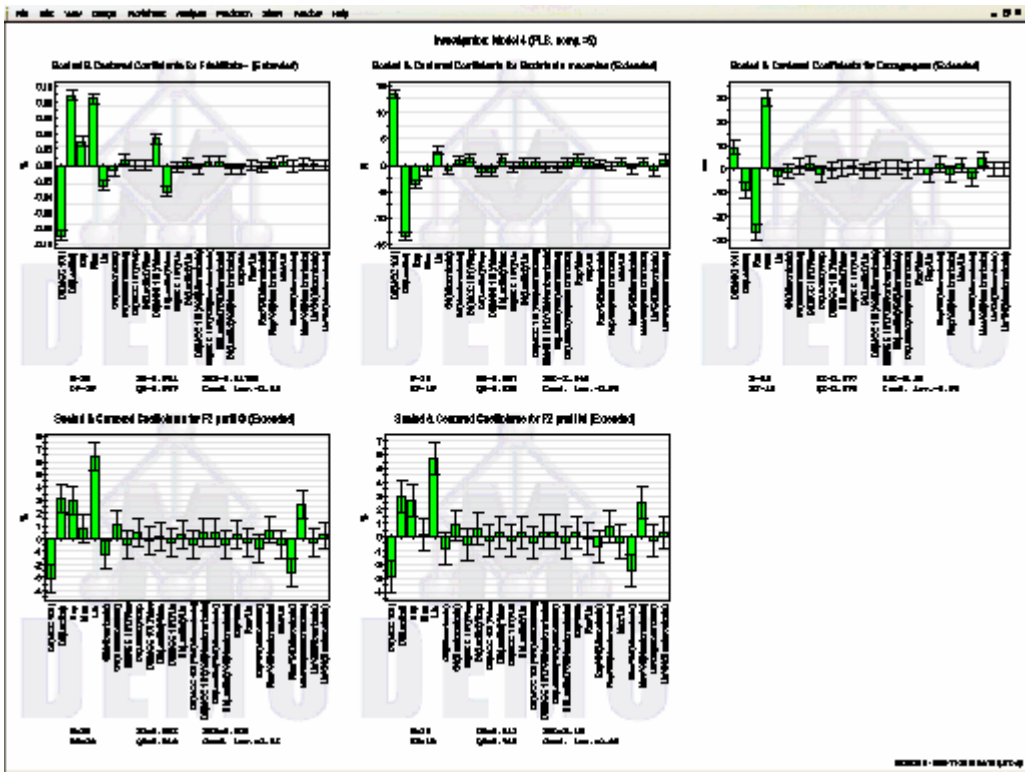

Fig. 8. Influenţa factorilor de formulare asupra parametrilor friabilitate, rezistenţă mecanică, dezagregare, factor de similaritate profil de dizolvare (glibenclamidă), factor de similaritate profil de dizolvare (metformin) (Coefficient Plot).

de admisibilitate de 0,1 %. Rezistenţa mecanică a prezentat valori satisfăcătoare, cuprinse între 67 şi 110 N. Dezagregarea comprimatelor a fost de 40-179 secunde, situându-se sub limita de 15 minute pentru comprimate neacoperite prevăzută de *Farmacopeea Europeană*. Factorul de similaritate F2G a avut valori de 40,5-69,3, iar F2M de 50,2-69,7.

DISCUŢII

Calitatea fitării a fost evaluată prin determinarea parametrilor statistici R_c şi Q_c, prin analiza varianţei (testul Anova) şi prin trasarea curbelor de dependenţă.

Rezultatele obţinute în urma evaluării calităţii fitării (tab. V) au fost satisfăcătoare pentru toţi factorii dependenţi investigaţi, reproductibilitatea modelului prezentând valori de 0,991342 % pentru friabilitate, 0,992863 % pentru rezistenţă mecanică, 0,990329% pentru dezagregare, 0,956383% pentru F2G şi 0,810507% pentru F2M.

Rezultatele testului Anova (tab. VI şi fig. 2-6) arată că, pentru toate răspunsurile "p" este mai mic de 0,05 pentru model şi este mai mare de 0,05 pentru eroare în ceea ce priveşte toţi factorii investigaţi. În consecinţă, variaţia rezultatelor se datorează modificării nivelurilor factorilor de formulare conform planului experimental şi nu unei variaţii aleatoare date de erori experimentale.

Graficele - curbele de dependenţă a valorilor observate (rezultate) în funcţie de valorile estimate de model (fig. 7) - indică o aliniere

satisfăcătoare a punctelor experimentale pe o dreaptă (diagonală la 45°), respectiv o bună fitare a modelului pentru toţi parametrii investigaţi: friabilitate, rezistenţă mecanică, dezagregare, similaritate profil de dizolvare glibenclamidă şi similaritate profil de dizolvare metformin.

În urma analizei diagramelor Coefficient Plot, factorii de formulare care influenţează major friabilitatea comprimatelor sunt: tipul de diluant, masa comprimatului şi procentul de dezagregant utilizat (fig. 8).

Friabilitatea scade o dată cu micşorarea masei comprimatului şi a procentului de dezagregant şi concomitent cu introducerea în formulă a liantului adăugat extragranular.

Factorii de formulare care influenţează rezistenţa mecanică a comprimatelor sunt: tipul de diluant, procentul de dezagregant şi cantitatea de liant introdusă extragranular (fig. 8).

Rezistenţa mecanică a comprimatelor este superioară în cazul utilizării celulozei microcristaline tip 101 ca diluant majoritar, creşte la introducerea liantului extragranular şi scade concomitent cu mărirea procentului de dezagregant utilizat în formulă .

Factorii de formulare care influenţează major dezagregarea comprimatelor sunt: masa comprimatului, procentul de dezagregant, tipul de diluant şi prezenţa liantului extragranular (fig. 8).

Dezagregarea comprimatelor devine mai rapidă o dată cu mărirea procentului de dezagregant şi scade o dată cu introducerea liantului extragranular.

Factorii de formulare care influenţează semnificativ similaritatea profilului de dizolvare a comprimatelor sunt următorii: tipul de diluant, procentul de dezagregant, prezenţa liantului extragranular şi sortul de glibenclamidă (micronizat/nemicronizat) utilizat (fig. 8).

CONCLUZII

Cercetarea unor formulări noi cu substanţe antidiabetice a avut în vedere stabilirea asocierilor cu excipienţi convenabili, prelucrate prin tehnologii care să asigure calitatea produsului final, realizat sub formă de comprimate. În acest sens, au fost studiate asocieri ale substanţelor active cu diferite proporţii de excipienţi, care să asigure cedarea lor corespunzătoare din forma farmaceutică elaborată.

Prepararea comprimatelor cu eliberare imediată ce conţin clorhidrat de metformin/glibenclamid 500 mg/2,5 mg s-a realizat printr-o metodă bazată pe un procedeu de granulare umedă a substanţei active majoritare din formulă.

Conform datelor prezentate (Q_2, R_2, Anova, curbele de dependenţă) se poate concluziona că răspunsurile experimentale se potrivesc modelului experimental ales.

Rata de eliberare a glibenclamidului şi a clorhidratului de metformin s-a îmbunătăţit succesiv cu mărirea proporţiei de dezagregant din formulă, micşorarea proporţiei de diluant din comprimat, introducerea liantului extragranular şi cu folosirea unui sort de glibenclamidă micronizat.

MULŢUMIRI

Colectivului de Cercetare din cadrul Departamentului Dezvoltare Farmaceutică, al Antibiotice S.A., Iaşi, România.

STUDIU CLINIC ASUPRA DISTRIBUŢIEI LEZIUNILOR DENTARE NECARIOGENE LA POPULAŢIA ADULTĂ

Magdalena Curcă, I. Dănilă
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină Dentară
Disciplina de Dentistică Preventivă

CLINICAL STUDY ON THE DISTRIBUTION OF TOOTH WEAR OF THE ADULT POPULATION (Abstract): Tooth wear is becoming increasingly significant in the developed societies, because the etiological factors are frequently present in the daily life. The aim of this study was to assess the distribution of the tooth wear of the adult population in a private practice of dentistry. **Material and method**: The group of study had 614 patients, structured on the following subgroups of age: 18- 30 years, 31-40, 41-50, 51-65 and more than 65 years old. Each patient had a clinical exam and a questionnaire for the diet and the lifestyle, spotlighting the etiology of tooth wear. **Results**: attrition was the most frequent (55.7%), followed by abrasion (32.7%), erosion affected 7.5% of the patients and abfractions are the least frequent (4.1%). Erosions (9.7%) and attritions (59.9%) are more frequent at the feminine gender, and abrasions (40.4%) at the masculine gender. More than half of the abfractions (56%) were found at the youth patients (18-30 years old). Erosions were found in the 31-40 years subgroup at almost 40% of the patients; in the 41-50 years subgroup, abrasion and erosion were found in equal proportions. Abrasion prevails at the 51-65 years subgroup (30.8%). 72% of the consumers of acidic fruits had dental erosions. **Conclusion**: Tooth wear is under the influence of the diet and the age factor. **Key words**: ABRASION, ATTRITON, EROSION, ABFRACTION

Leziunile dentare necariogene sunt descrise ca un fenomen de suprafaţă, spre deosebire de leziunile carioase, în care sunt implicate atât leziuni de suprafaţă cât şi de profunzime. Leziunile dentare necariogene evoluează cu demineralizarea ţesuturilor dentare subiacente, fenomen ce se continuă constant în timp (1).

Leziunile dentare necariogene reprezintă un tip de patologie din ce în ce mai des întâlnită în societăţile dezvoltate, datorită acţiunii factorilor etiologici, care sunt tot mai frecvenţi în viaţa de zi cu zi (dietă, factori de mediu, obiceiuri vicioase, creşterea gradului de igienă orală) (2).

Scopul acestui studiu a fost evaluarea distribuţiei leziunilor dentare necariogene la populaţia adultă dintr-un cabinet privat de medicină dentară.

MATERIAL ŞI METODĂ

Studiul a fost realizat pe un lot de 614 de pacienţi care s-au prezentat la un cabinet de medicină dentară privată din Iaşi pe o perioadă de 3 ani (2006-2009). Lotul a cuprins 285 de pacienţi de sex masculin şi 329 de sex feminin; 155 subiecţi s-au încadrat în intervalul de vârstă 18-30 ani, 170 în intervalul 31-40 de ani, 129 în intervalul 41-50 de ani, 147 în intervalul 51-65 de ani şi 13 de pacienţi aveau peste 65 de ani.

Criteriile de selecţie a subiecţilor au urmărit pacienţi cooperanţi cu vârsta peste 18 de ani şi o valoare a indicelui Smith şi Knight mai mare decât zero.

Pentru fiecare pacient s-a realizat exa-

men clinic şi s-a aplicat un chestionar referitor la obiceiurile alimentare şi modul de viaţă, evidenţiind factorii implicaţi în etiologia diferitelor tipuri de leziuni necariogene, în urma căruia s-au consemnat următoarele date :

- generale (nume, prenume, vârstă, mediu rural sau urban, studii, antecedente generale şi stomatologice) ;
- tipul de băuturi consumate (băuturi acide, băuturi pentru sportivi, ceaiuri, alcool, sucuri naturale din fructe) ;
- eventuale simptome gastrice (vomă, reflux gastro-esofagian, gust acid în cavitatea orală) ;
- tipul de medicaţie ;
- antecedente personale generale, în contextul patologiei asociată altor boli.
- expunerile la mediile acide sau abrazive ;
- gradul de igiena dentară (tehnica, abrazivitatea pastei de dinţi şi orarul de periaj) ;
- obiceiuri vicioase (bruxismul, interpunerea diverselor obiecte între dinţi).
- statusul odonto – parodontal
- leziunile necariogene au fost consemnate diferenţiat în : eroziuni, abrazii, atriţii şi abfracţii.

Datele obţinute au fost centralizate şi analizate utilizând SPSS 16 pentru Windows.

REZULTATE

În urma analizării datelor s-au obţinut următoarele rezultate : 20,19% dintre pacienţi provin din mediul rural şi 79,8% din mediul urban ; 479 de subiecţi au studii medii şi 135 au studii superioare. Din întregul lot de studiu, 4,07% din subiecţi consumă în mod frecvent fructe acide (25), 25,89% băuturi carbogazoase (159), 15,9% sunt consumatori de dulciuri (98), iar 18,89% sunt consumatori de alcool (116). La 44,65% dintre subiecţi am considerat că igiena orală este satisfăcătoare (274), la 24,59% bună (151), la 30,78% igiena fiind nesatisfăcătoare (189). În ceea ce priveşte contactul cu

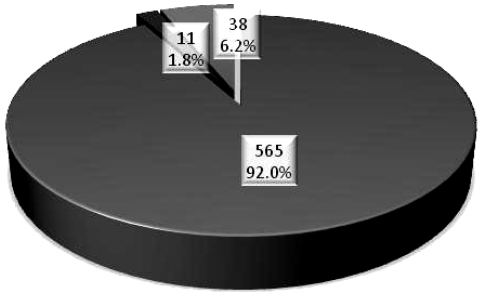

Fig.1. Distribuţia lotului în funcţie de factorii de mediu

factorii de mediu poluanţi 92% (565) dintre subiecţii lotului nu au avut, pe când 6,2% (38) au fost expuşi mediului abraziv şi 1,8% (11) mediului acid (fig.1).

Am evaluat leziunile dentare necariogene în funcţie de sex, constatând existenţa semnificaţiei statistică – datele diferă ca distribuţie semnificativ (tab. I). Din frecvenţa de repartiţie se observă diferenţe majore pentru abrazie unde persoanele de sex masculin se întâlnesc în procent mult mai mare ajungând la 40% (115) faţă de cele de sex feminin, în proporţie de doar 26% (86). Tot diferenţe majore se întâlnesc la eroziune unde persoanele de sex feminin sunt în proporţie aproape dublă faţă de cele de sex masculin (9,7% comparativ cu 4,9%). La leziunile dentare necariogene de tipul atriţiei nu constatăm diferenţe majore în funcţie de sex, pacienţii de sex masculin întâlnindu-se în procent de 50,9%, faţă de pacienţii de sex feminine, care se întâlnesc în proporţie de 59,9%.

În cazul abfracţiei, nu constatăm nici o diferenţă în funcţie de sex (3,9% la sexul masculin, faţă de 4,3% la sexul feminin).

În ceea ce priveşte prevalenţa leziunilor dentare necariogene, 32,7% (201) dintre subiecţi prezintă abrazii, 55,7% (342) prezintă atriţii, 4,1% (25) prezintă abfracţii, iar 46 (7,5%) dintre pacienţi au fost diagnosticaţi cu eroziuni dentare (fig. 2).

TABELUL I

Testul Pearson-Chi pătrat pentru repartiţia leziunilor necariogene în funcţie de sex

Chi-Square Tests			
	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	16.425[a]	3	.001
N of Valid Cases	614		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 11.60.			

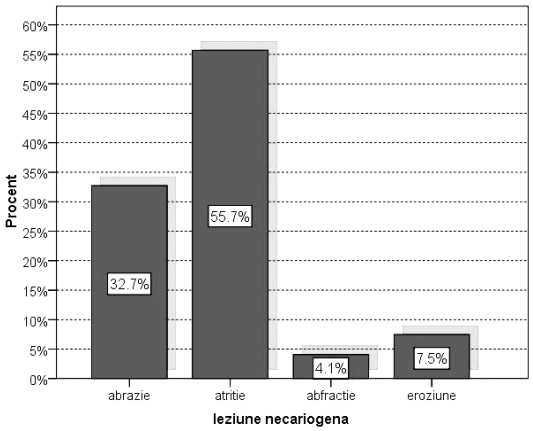

Fig. 2. Distribuţia leziunilor dentare necariogene

Peste jumătate din cazurile cu abfracţie (56%) se întâlnesc la vârstă mică (18-30 ani). Totuşi procente importante din grupele celelalte de vârstă se găsesc şi în celelalte tipuri de leziuni necariogene. Eroziunea se întâlneşte la grupa de vârstă 31-40 de ani în procent de aproape 40% din cazuri. La grupa de vârstă 41-50 de ani, abrazia şi eroziunea se găsesc în procente apropiate (19%), atriţia în procent puţin mai mare (22,8%), iar abfracţia în procent mai mic (12%). La grupul de vârstă 51-65 de ani predomină abrazia cu procent de 30,8% şi atriţia cu un procent de 21,9% (fig. 3). Grupul peste 65 ani este slab reprezentat şi este generator de inconsistenţă statistică.

Am studiat leziunile dentare necariogene în relaţie cu ancheta alimentară, comparând ponderea fiecărui tip de leziune necariogenă (abrazie, atriţie, abfracţie şi eroziune) la pacienţii consumatori de fructe acide cu ponderea tipurilor de leziuni necariogene la lotul martor, acesta constând în grupul de pacienţi la care ancheta alimentară nu a evidenţiat consumul niciunui aliment care poate determina apariţia unei patologii la nivelul cavităţii orale (140 de pacienţi, dintre care 43 prezintă abrazie, 81 atriţie, 3 prezintă abfracţie şi 13 prezintă leziuni erozive).

Studiind leziunile dentare necariogene în funcţie de consumul de fructe acide (fig. 4), am evidenţiat următoarele rezultate:

- dintre cei 25 de pacienţi cu leziuni dentare necariogene consumatori de fructe acide, doar unul prezintă abrazie (4%), comparativ cu 30,7% dintre pacienţii din lotul martor.

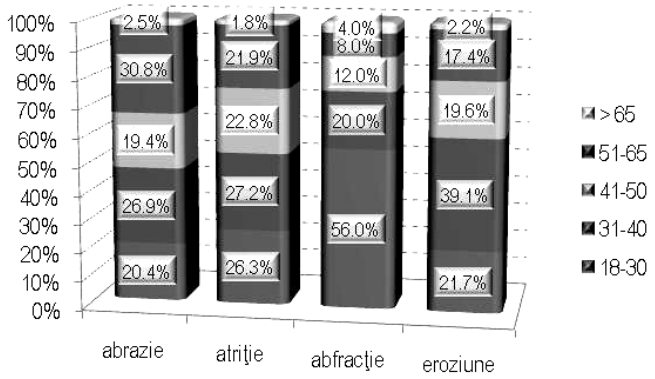

Fig. 3. Prevalenţa leziunilor dentare necariogene comparativ pe intervale de vârstă (%)

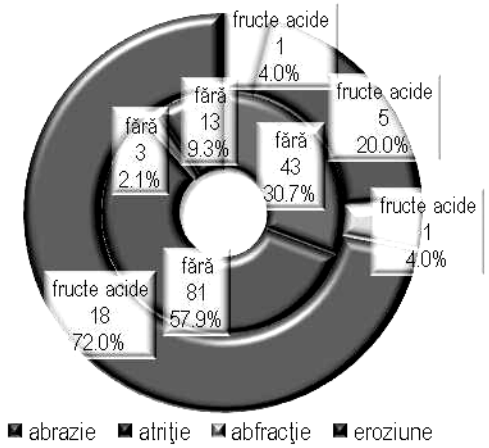

Fig. 4. Prevalenţa leziunilor dentare necariogene la consumatorii de fructe acide

- 20% dintre pacienţii consumatori de fructe acide au fost diagnosticaţi cu atriţie, faţă de 57,9% dintre pacienţii din lotul martor.
- un singur pacient consumator de fructe acide prezintă abfracţie, faţă de 3 pacienţi din lotul martor
- dintre cei 25 de pacienţi consumatori de fructe acide, 18 (72%) prezintă leziuni necariogene de tip eroziv, comparativ cu 13 pacienţi (9,3%) dintre pacienţii din lotul martor.

DISCUŢII

Leziunile dentare necariogene prezintă etiologie plurifactorială, pierderea de substanţă dură dentară având diferite cauze. Eroziunea, atriţia şi abrazia interacţionează şi contribuie la afectarea morfologiei şi funcţionalităţii dentare (1,3). Datele despre prevalenţa uzurilor dentare arată faptul că leziunile dentare necariogene sunt o patologie des întâlnită. Prevalenţa eroziunilor dentare este mai mare la adulţii tineri, ceea ce are ca explicaţie modificările în dietă şi în modul de viaţă la care sunt supuse aceste grupuri de vârstă (4).

Leziunile dentare necariogene tind să devină o patologie relativ frecventă a cavităţii orale, din acest motiv devenind o necesitate identificarea grupurilor cu risc şi aplicarea măsurilor preventive specifice la nivel populaţional (1).

CONCLUZII

Atriţia este diagnosticul cel mai frecvent întâlnit (55,7% din cazuri), fiind urmat de abrazie (32,7%), eroziunile se întâlnesc la 7,5% dintre subiecţi, abfracţiile fiind leziunile cel mai rar întâlnite (4,1%).

Frecvenţa eroziunilor este mai mare la sexul feminin decât la sexul masculin, iar leziunile de tipul abraziei apar mai frecvent la sexul masculin.

Abfracţia se întâlneşte mai frecvent la grupa de vârstă 18-30 de ani, abrazia şi de atriţie apar cu în special la grupele de vârstă 31-40, 41-50 şi 51-65 de ani, pe când leziunile erozive apar la grupa de vârstă 31-40 de ani.

Factorul alimentar influenţează tipul leziunilor dentare necariogene, 72% dintre consumatorii de fructe acide prezentând eroziuni dentare.

GENERALIZED GINGIVAL ENLARGEMENT – EARLY CLINIC MANIFESTATION IN ACUTE LEUKEMIA. CASE REPORT (Abstract): Leukemia is a hematological disorder arises from a hematopoietic stem cell characterized by a disordered differentiation and proliferation of neoplastic cells. Rapidly forming generalized gingival hyperplasia is usually the first sign of this disease (especially in acute forms). This case report describes a 54-year old female who presented rapid gingival enlargement in only three weeks time, heralding the presence of acute monocytic leukemia (AML – FAB M5). The patient was immediately referred for hematologic management, but died five weeks later. Dentists and generalists should always be on guard to observe any oral manifestations that may lead to the early diagnostic of systemic diseases. **Key words**: ACUTE LEUKEMIA, GINGIVAL ENLARGEMENT

HISTO-ANATOMY OF VEGETATIVE ORGANS OF SOME *ARTEMISIA* SPECIES

HISTO-ANATOMY OF VEGETATIVE ORGANS OF SOME *ARTEMISIA* SPECIES (Abstract): **Aim**: Comparative study of three medicinal species of *Artemisia* widespread in our country, focusing on the anatomical structures that contain bioactive compounds, such as glandular hairs and secretory ducts. **Material and methods**: The roots, stems and leaves of *Artemisia annua, A. vulgaris* and *A. absinthium* were preserved in 70% alcohol. Cross-sections were made using the common methodology and were further analyzed microscopically. **Results**: In the secondary structure of the stem there are differences related to the degree of lignification, more pronounced in *A. annua*, and the special structure of the phloem in *A. vulgaris*. The leaf of *A. vulgaris* presents more vascular bundles in the median rib and *A. annua* has fewer protective trichomes on the leaf lamina. The root has a secondary structure with differences in the number of secretory ducts and cortex size. **Conclusions**: The structure of the stem and root is typical secondary with differences in the number and size of the secretory elements. Depending on light exposure, the leaf presents a heterogeneous symmetric or asymmetric mesophyll. **Keywords**: *ARTEMISIA*, HISTO-ANATOMY, SECRETORY ELEMENTS.

Artemisia is one of the largest genera of *Asteraceae* family, with over 500 species spread mainly in the Northern Hemisphere. The genus includes aromatic plants, used for their antimalarial, antiviral, anticancer, antipyretic, analgesic, anti-inflammatory, antioxidant, hepatoprotective, antispasmodic, anticoagulants, anti-ulcer, antianginal, antiseptics and immunostimulating effects. Researches on *Artemisia* species have intensified along with the discovery of artemisinin, the antimalarial compound from *Artemisia annua* (1).

Artemisia genus is characterized by morphological and phytochemical variability and frequently shows polyploidy. Therefore, the different chemotypes and cytotypes synthesize different compounds with diverse biological activity (2). Romanian flora comprises 20 species of *Artemisia*, and the three species (*A. annua, A. vulgaris, A. absinthium*) selected for this study are widespread and well known in traditional medicine (3).

MATERIAL AND METHODS

The vegetative organs belonging to the three species - roots, stems, leaves - were collected during the flowering period (July-September) in the areas surroundings of Iaşi

town. Plants were identified at the Department of Vegetal Biology, Faculty of Pharmacy, Iaşi "Grigore T. Popa" University of Medicine and Pharmacy, and voucher specimens were stored in the department herbarium. The plant material was preserved in 70% alcohol (v/v). Cross sections were made using a hand microtome and a razor and then stained with carmine red and iodine green (4,5). Microscopic preparations were analyzed using a Nikon Eclipse E400 microscope equipped with a Nikon D90 camera.

RESULTS AND DISCUSSION

The structure of the **root of *A. absinthium*** is typically secondary, built on account of the activity of both secondary meristems. It presents a cork cambium with relatively thick cork on the outside and a slightly collenchymatous phelloderm inward (fig. 1). In the internal part of the cortex, there are large secretory canals, tangentially elongated, and arranged in a circle around the central cylinder (fig. 2).

The vascular cambium produces to the exterior an annular area of secondary phloem and a compact central area of secondary xylem with a high degree of lignification, both crossed by numerous medullary rays, partially lignified in the xylem (fig. 2). In the phloem there are alternating parenchyma zones (in which secretory ducts are found) and tangential areas of sclerenchyma fibers. The elements surrounding the fibers have often strong collenchymatous walls. The actual phloem, located near the cambium, forms a relatively thin zone consisting of sieve tubes and companion cells. The secondary xylem shows wood vessels of different diameters, solitary or grouped, situated disorderly in the mass of sclerenchyma fibers. The xylem parenchyma is reduced and completely lignified.

According to the studies by Toma and Rugină (6), *A. absinthium* is missing the cork area in the secondary xylem, which occurs in many *Artemisia* species from arid climates, having the role of protecting the roots against dehydration. This cork is formed through the activity of a deeper cork cambium which gives rise every year to 1-2 layers of cork cells, arranged at the periphery of the annual growth rings of the secondary xylem (6).

The cross section through ***A. annua* root** has a circular outline. It presents cork on the outside followed by a thin cortex bordered on the interior by a visible endoderm surrounding the bulky central cylinder (fig. 3). In the secondary cortex, there can be seen rare secretory ducts, slightly elongated tangentially, isolated or in small groups.

In the central cylinder there is a circular area of phloem surrounding the xylem. The phloem ring is thin, showing two opposite areas with bundles of sclerenchyma fibers (fig. 3,5). Most of the stele is occupied by the compact xylem area, highly lignified, composed of large wood vessels with radial arrangement. The pith is missing. The vascular bundles are separated by medullary rays which gradually widen from the center to the periphery. All reported anatomical items define, at the root level, a secondary structure with massive areas of secondary phloem and xylem.

The outline of ***A. vulgaris* root** cross section is circular. In the periphery there is an area of thick cork and inward, there is a phelloderm area with parenchyma cells, both resulting from the activity of the cork cambium.

In the central cylinder (fig. 4) there is a thin phloem area, with particular structure and annular shape, then a large central xylem area, consisting of two annual growth rings corresponding to the second-

ary structure. Both phloem and xylem are crossed by several multi-layered medullary rays, formed mostly of cellulosic parenchyma and visibly wider in the phloem.

In the stele, there are isolated secretory canals, scattered in the phloem. More obvious are the grouped secretory ducts in the internal region of secondary cortex, almost glued to the endoderm, near the bundles of phloem fibers (fig. 6).

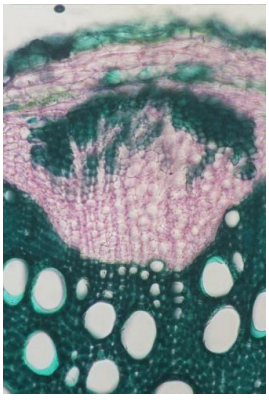

Fig. 5. *A. annua* root – secondary phloem, vascular cambium and secondary xylem (20×)

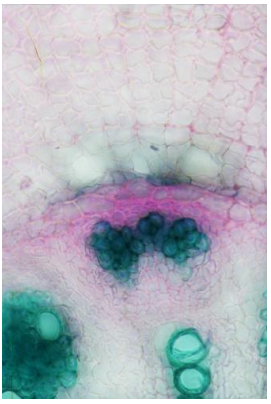

Fig. 6. *A. vulgaris* root – internal cortex with secretory ducts, endoderm, bundles of phloem fibers (20×)

The cross section of ***A. absinthium*** **stem** has a circular ribbed contour and presents an epidermis covered by numerous T-shaped protective trichomes. The trichomes are multicellular, with the terminal part having the shape and position of the compass needle (fig. 8). Near the ribs, under the epidermis there are large collenchyma masses (fig. 7); the rest is represented by a narrow parenchyma cortex. Due to the pronounced lignification of stem, the cross sections were made mostly in the tip area.

In the central cylinder, the secondary structure is formed on the basis of the vascular cambium. Only the intrafascicular cambium works normally, producing less phloem outwards and more xylem inwards. In the primary xylem, vessels are arranged in radial rows, continuously or discontinuously, separated by cellulosic parenchyma (7). Both vascular tissues, although of secondary origin, form a fascicular type structure. Vascular bundles are provided with strong sclerenchyma sheaths on the phloem side (having the aspect of sclerenchyma caps). The vascular bundles seem to touch each other on the sides, being linked by lignified tissue areas (fig. 7). In the center section there is cellulosic parenchyma pith, of lacunose type.

In ***A. annua*** **stem**, depending on the cutting area - top, middle and base - there can be seen a circular shape with more or less pronounced ribs. Compared to the other two species, in this case there is a higher degree of lignification, a reduced bark and greater number of ribs - 19. The epidermis has small cells covered by a cuticle, few T-shaped protective trichomes and characteristic glandular hairs of *Asteraceae* type. Under the epidermis, close to the ribs, there are collenchyma areas followed by a small parenchyma cortex and the endoderm, visible especially next to the ribs.

The central cylinder structure is similar to that of *A. absinthium*. The vascular bundles, of collateral type, are larger near the ribs and smaller between them, connected by a band of sclerenchyma tissue. Outside, above the phloem, there is a sizeable cap of supporting tissue (fig. 9). The multi-layered intrafascicular cambium continues with interfascicular areas, forming a continuous band. The bulk of the section (approx. ¾) is occupied by pith parenchyma.

A. vulgaris **stem** section is similar in shape and contour with *A. absinthium* stem section, except that the number of ribs is smaller and they are more attenuated (fig. 10). On the epidermis, there are no protective hairs or only a small number of broken bases of trichomes can be seen. Next to the ribs, there are large collenchyma areas and a narrow parenchyma cortex.

Both phloem and xylem, although secondary in origin, are organized in bundles (fig. 11). A special type of phloem bundles is present where supporting elements with lignified walls are mixed with others having thin cellulosic walls; to the exterior, there is a consistent sclerenchyma cap (fig. 12). Among these vascular bundles, there are some made only of phloem elements. All of them, together with the cellulosic parenchyma between them, form a ring that shows to its internal face a visible multilayered cambium. Towards the center of the section there is a xylem band consisting of secondary xylem on the outside and primary xylem on the inside. The center of the section is represented by cellulosic parenchyma pith, of lacunose type.

A. absinthium shows an equifacial structure of the **leaf** lamina with symmetrical heterogeneous mesophyll with two rows of palisade parenchyma cells to the upper face and only one layer to the lower face. Between the two areas of palisade tissue there

are two layers of spongy parenchyma cells. The palisade cells are relatively short, with wavy side walls and larger intercellular spaces to the underside of the lamina.

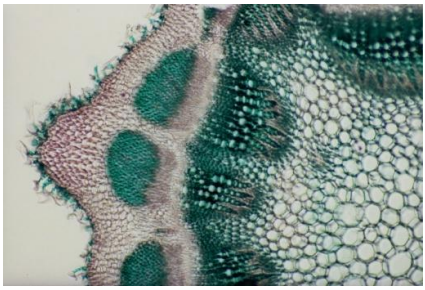

Fig. 7. *A. absinthium* stem – detail (10×)

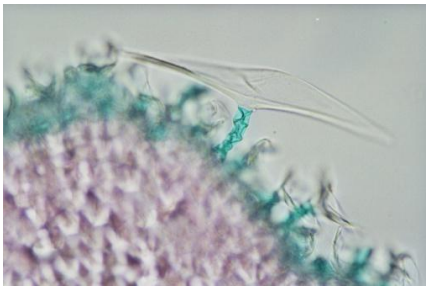

Fig. 8. *A. absinthium* stem – epidermis with T-shaped protective trichomes (40×)

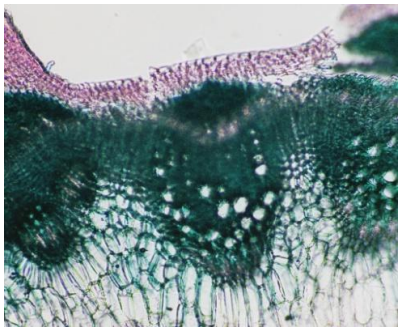

Fig. 9. *A. annua* stem – vascular bundles connected by a band of sclerenchyma tissue (10×)

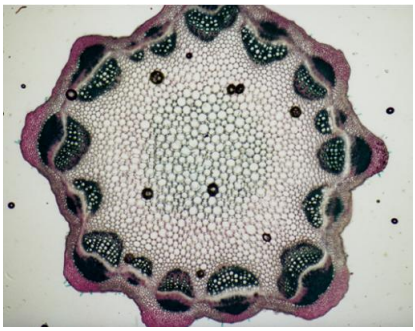

Fig. 10. *A. vulgaris* stem – general view (4×)

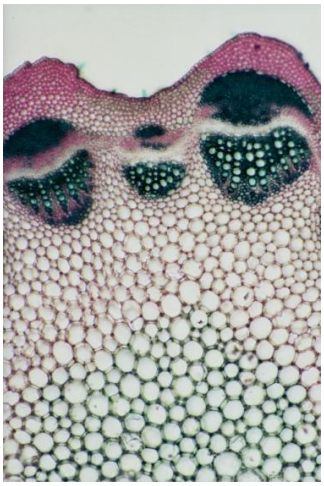

Fig. 11. *A. vulgaris* stem – vascular bundles with sclerenchyma cap (10×)

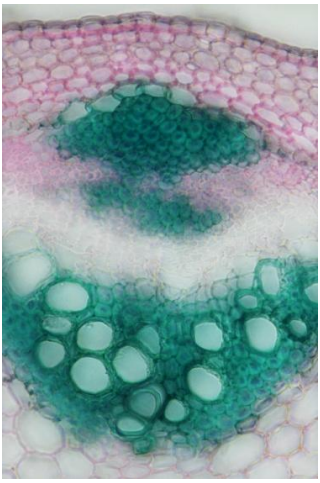

Fig. 12. *A. vulgaris* stem – detail of vascular bundle (20×)

The midrib, prominent on both sides, is more visible on the lower part and presents palisade tissue beneath the upper epidermis (fig. 13). The mid-stem and upper leaves present a single vascular bundle next to the midrib and a reduced collenchyma band above the lower epidermis (fig. 13), whereas the basal leaves show two vascular bundles and collenchyma bands under both epidermises. (fig. 14). In the parenchyma tissue around the vascular bundles of the midrib there are few secretory canals.

The epidermises are wavy, composed of cells with weakly thickened external walls and barely cutinized. On both epidermises - but more frequently on the lower one – characteristic T-shaped protective hairs are present. These trichomes have the terminal cell shaped like a compass needle, arranged perpendicularly to a stalk consisting of 3-5 cells. Biseriate glandular hairs of *Asteraceae* type, with 8 secretory cells, are found in the depressions of lower epidermis.

The lamina is hypostomatic, with anomocytic stomata (8). According to Halmai and Novak (9), in *A. absinthium* only the leaves with both sides exposed to sunlight have equifacial structure. The shaded leaves have bifacial structure due to the asymmetric heterogeneous mesophyll (9).

In the cross section through ***A. annua*** **leaf**, a very evident prominence can be noticed, next to the midrib, towards the upper and lower face (fig. 15). The leaf lamina presents a symmetric heterogeneous mesophyll (fig. 16). Under both epidermises there is a monolayer palisade parenchyma and between palisades there is a spongy parenchyma of 2-3 layers of cells. The median rib (fig. 15) has a collateral vascular bundle centrally located and assimilation tissue.

Next to the midrib, the upper and lower epidermises have collenchymatous cell walls.

In the parenchyma surrounding the vascular bundle of the midrib, there are secretory ducts. On both epidermises can be seen the bases of broken protective hairs, situated mostly on the midrib, and also biseriate glandular hairs of *Asteraceae* type, especially on the lower epidermis. It is important to emphasize the size of *A. annua* leaf, considerably smaller compared to the other two species.

According to Duke et al. (10) there are protective T-shaped trichomes and glandular hairs with biseriate 10-celled glands on the leaves, stems and flowers. There are two biotypes of *A. annua*, with and without secretory trichomes; the biotype lacking glandular hairs does not contain artemisinin. The glandular hairs are more prominent on corolla and floral receptacle than on leaves, stems or bracts (10).

It has been shown that glandular hairs are the site of artemisinin synthesis. Glandular hairs are made of 2 columns of 5 cells which are covered by a common cuticle enveloping the first 3 pairs of apical cells. Since artemisinin is autotoxic for *A. annua*, its location in the subcuticular space prevents the contact of substance with live parts of the plant, while providing protection from insects, herbivores and pathogens (11).

The cross section through ***A. vulgaris*** **leaf** presents a projection next to the median rib, even deeper towards the lower face compared to that of *A. absinthium*. In the midrib there are 3 big vascular bundles of collateral type, centrally located, and 2 smaller ones on the sides, all placed in a general parenchyma devoid of chloroplasts; the assimilation tissue is missing (fig. 17).

The large vascular bundles have small sclerenchyma sheaths at extremities. Above the central bundle there is a secretory canal of volatile oil surrounded by cells arranged

radially (fig. 17). As in *A. absinthium* leaf, next to the midrib, under both epidermises, there is collenchyma bands, the lower one being better developed.

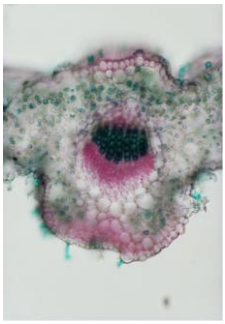

Fig. 13. *A. absinthium* upper leaf – detail of midrib (20×)

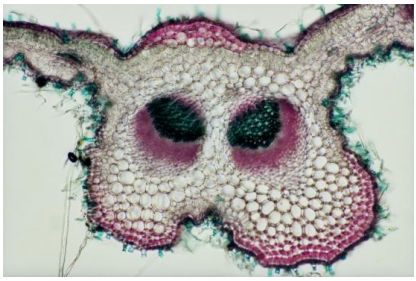

Fig. 14. *A. absinthium* basal leaf – detail of midrib (10×)

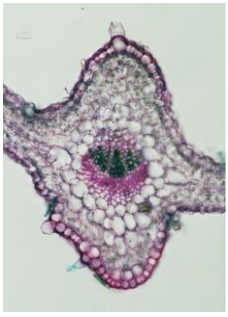

Fig. 15. *A. annua* leaf – detail of midrib (20×)

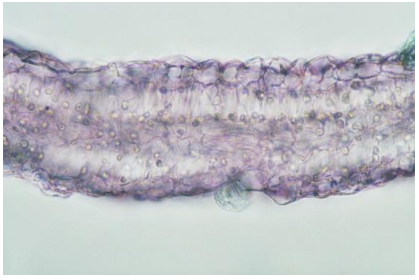

Fig. 16. *A. annua* leaf – detail of mesophyll (40×)

Fig. 17. *A. vulgaris* leaf – midrib detail (10×)

Fig. 18. *A. vulgaris* leaf – detail of mesophyll (40×)

The leaf blade has an equifacial structure with symmetrical heterogeneous mesophyll (fig. 18), showing one-layered palisade tissue under both epidermises, with shorter cells in the lower palisade. The upper epidermis has bigger cells with outer walls thicker than the lower epidermis (fig. 18). Protective trichomes, more frequent on

the lower epidermis, are also T-shaped but slightly different from those of *A. absinthium*: their terminal part has the form of two very long arms.

CONCLUSIONS

Our comparative histo-anatomical study of the three *Artemisia* species revealed a number of resemblances, especially in the stem structure. The stem has many ribs hardened with angular collenchyma, a reduced bark and a central cylinder with an evident secondary structure, and a pith parenchyma in the centre. Differences appear in the degree of lignification, more pronounced in *A. annua* stem and the special structure of phloem in *A. vulgaris* stem.

As to the leaf structure, the similarities are linked to the plant ability to adapt to strong light conditions – mesophyll with symmetrical heterogeneous structure, or to shade – mesophyll with asymmetrical heterogeneous structure. The differences refer to the small size of *A. annua* leaf, a greater number of vascular bundles in *A. vulgaris* midrib and a reduced number of trichomes in *A. annua* leaf. With regard to root anatomy, all the species have a typically secondary structure, with distinctions in the number and dimensions of the secretory ducts, but also in the cortex size – smaller in *A. annua* in comparison with the other two species.

GRAPHICAL USER INTERFACE WITH APPLICATIONS IN SUSCEPTIBLE-INFECTIOUS-SUSCEPTIBLE MODELS (Abstract): Practical significance of understanding the dynamics and evolution of infectious diseases increases continuously in contemporary world. The mathematical study of the dynamics of infectious diseases has a long history. **Aim:** By incorporating statistical methods and computer-based simulations in dynamic epidemiological models, it could be possible for modeling methods and theoretical analyses to be more realistic and reliable, allowing a more detailed understanding of the rules governing epidemic spreading. **Material and methods**: To provide the basis for a disease transmission, the population of a region is often divided into various compartments, and the model governing their relation is called the compartmental model. To present all of the information available, a graphical user interface provides icons and visual indicators. The graphical interface shown in this paper is performed using the MATLAB software *ver.7.6.0*. MATLAB software offers a wide range of techniques by which data can be displayed graphically. The process of data viewing involves a series of operations. To achieve it, I had to make three separate files, one for defining the mathematical model and two for the interface itself. **Results**: Considering a fixed population, it is observed that the number of susceptible individuals diminishes along with an increase in the number of infectious individuals so that in about ten days the number of individuals infected and susceptible, respectively, has the same value. If the epidemic is not controlled, it will continue for an indefinite period of time. By changing the global parameters specific of the SIS model, a more rapid increase of infectious individuals is noted**. Conclusions:** Using the graphical user interface shown in this paper helps achieving a much easier interaction with the computer, simplifying the structure of complex instructions by using icons and menus, and, in particular, programs and files are much easier to organize. Some numerical simulations have been presented to illustrate theoretical analysis.
Keywords: INFECTIOUS DISEASES, SIS EPIDEMIC MODEL, GUI, MATLAB.

Classical research of Kermack and McKendrik (1927) (1) laid the foundations of mathematical modeling in the field of epidemic dynamics. Variables indicate the number of host individuals in various stages - susceptible, infectious and recovered. This formality is the current basis of dynamics modeling and evolution of infectious diseases. To prevent and control their spread, epidemic dynamics has played an essential part in investigating their transmission, predicting trends of development, estimating key parameters from the data published by health departments, under-

standing the characteristics of transmission and implementing prevention and control measures. Both history and reality show that, while people are faced with the threat of several infectious diseases, the importance of the investigation concerning transmission mechanism, spreading rules and strategy for prevention and control have increased rapidly, and such studies are a critical mission to be dealt with as quickly as possible.

In general, the mathematical models applicable in epidemiology divide the population into three compartments (2, 6):

- a susceptible one (marked S), in which all individuals are susceptible to the disease;
- an infected one, marked I, in which all individuals are infected by disease and are infectious;
- an "isolated" one, marked R (removed) in which all individuals are removed from the infected compartment, where S(t), I(t), R(t) denote the number of individuals of the three compartments at the point of time t .

MATERIAL AND METHODS

The Susceptible-Infected- Susceptible model with vital dynamics (births and deaths) is characterized by the following system of differential equations (1):

$$\begin{cases} \frac{dS}{dt} = \mu N - \mu S - \frac{\beta IS}{N} + \gamma I \\ \frac{dI}{dt} = \frac{\beta IS}{N} - \gamma I - \mu I \end{cases} \quad (1)$$

with initial conditions $S(0) = S_0 > 0$, $I(0) = I_0 > 0$ and $S(t) + I(t) = N$, where N is the total number of individuals and β is the total number of contacts. The SIS model shows an increased number of new-born babies in the susceptible compartment at a μN rate and a μS death rate, μI , respectively, where $\frac{1}{\mu}$ is the average life expectancy and $\frac{1}{\gamma}$ is the infectious period (2, 3). Deaths and births are balanced in such a way that total population N remains constant. This model is the simplest epidemiological model and is used for diseases, which do not confer immunity after infection. Susceptible individuals become infected and then become susceptible again after recovery. The model is an endemic one as the disease persists, and it is used in diseases such as gonorrhea, meningitis or streptococcal infections (4).

A graphical interface (Graphical User Interface) is an interface located between the user and electronic devices such as computers, hand-held devices (mp3 players, portable media players), electronic appliances and some office equipment. To present all available information and actions, a GUI provides icons and visual indicators, in contrast to text-based user interfaces, which provide names of commands to be typed in or text navigation (5, 7). This is intended to facilitate the user's work by eliminating the process of writing the software code.

RESULTS

The graphical user interface consists of a panel for displaying different graph views, a panel for controlling graphs and a panel for introducing and controlling parameters (fig. 1).

- **Graph display panel**: This area defines the "axes of coordinates" (abscissa and ordinate) required in graphic view of curves of solutions: S(t), I(t) (fig. 2).
- **Parameter control panel**: In this panel, values of each and every parameter can be changed. To choose the relevant model, one of the models that can be accessed from the top of the graph display panel is selected (fig. 3).

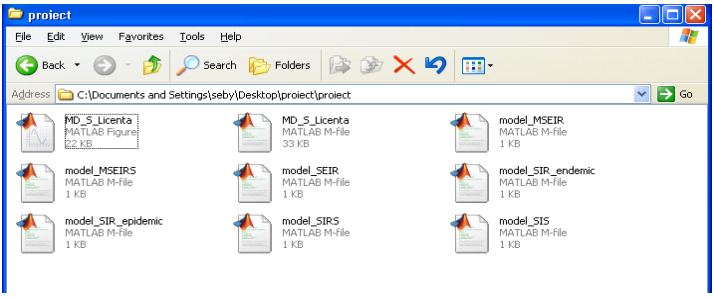

Fig. 1. Files contained by GUI

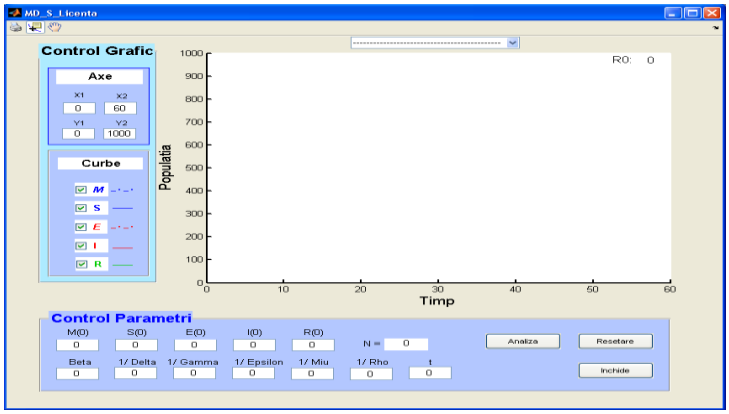

Fig. 2. Graphical user interface with applications in epidemiology

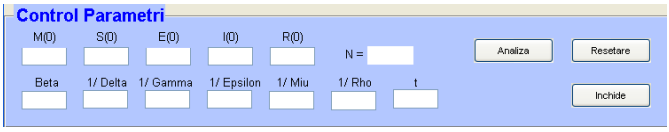

Fig. 3. Parameter control panel

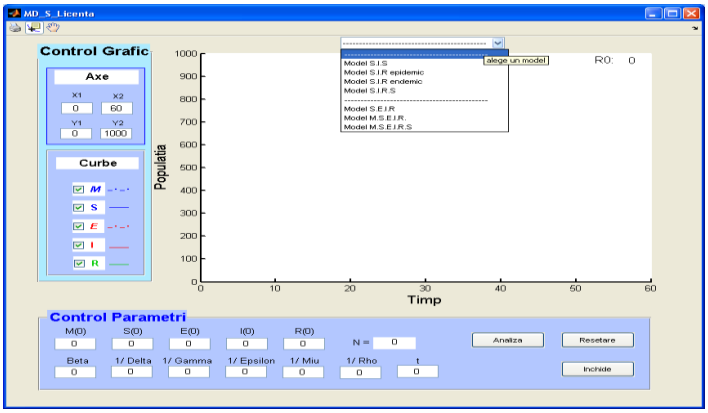

Fig. 4. Example of choosing a model

After having selected a model, the parameter values specific of the models under analysis must be introduced, and parameters that are not specific of the model analyzed will be set to zero. The "Reset" button is pressed to re-enter parameter values and the "Analysis" button is pressed to display the graph. To exit the program, the "Close" button is pressed.

• **Graphic control panel**: At the top, specific values to view the graph obtained will be introduced. Initially, these values are automatically set to the values displayed. Subsequently, according to the user's needs, these values can be modified. The selection buttons to display curves resulting from the analysis are placed at the bottom. Subsequent simulations have been made using epidemiological databases and considering an early time of the epidemic onset.

The SIS model described by the system of equations (1) is characteristic of diseases caused by bacteria. Infected individuals automatically move to susceptible class after recovery. Figure 4 considers a number of contacts of $\beta=5$ during the given time period and an infectious period of $\frac{1}{\gamma}=3$ days. The initial number of susceptible individuals is $S(0)=1000$, while the initial number of infectious individuals is $I(0)=10$. Life expectancy has an average value of $\frac{1}{\mu}=75$, while birth and death rate is $\mu=0.013$.

Should we change the global parameters characteristic of the SIS model, β and $\frac{1}{\gamma}$, we can see a more rapid increase of infectious individuals, corresponding to a lower point of balance reported to the S/I curves (approximately four days). It is also noted that a great variation of the infectious period (from three to ten days) causes a proportional variation of the basic reproductive number, from a value of $R_0=\frac{\beta}{\gamma+\mu}\approx 29$ in the case of a small infectious period, to a higher value, i. e. $R_0\approx 88$ for a incubation period of $\frac{1}{\gamma}=10$. This number R_0 is critical in the beginning of an epidemic (fig. 5, 6).

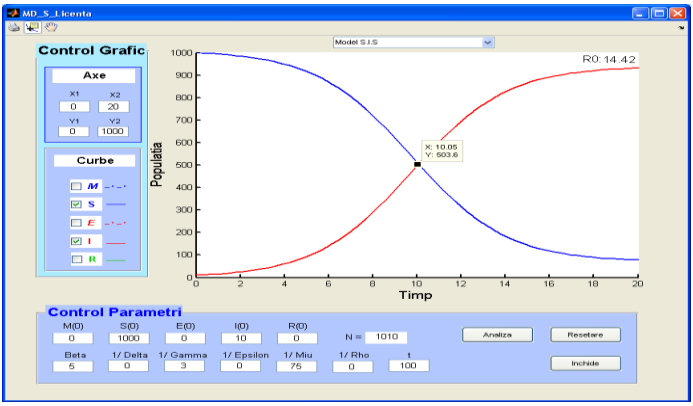

Fig. 5. SIS model analysis for $\beta=5$ and $\frac{1}{\gamma}=3$ values.

I assumed that each contact of an infected individual was with a non-infected, or susceptible. It is more realistic to assume that the number of susceptible contacts is a function of the number of susceptible persons in the population. We also need to specify an initial fraction of the infected population.

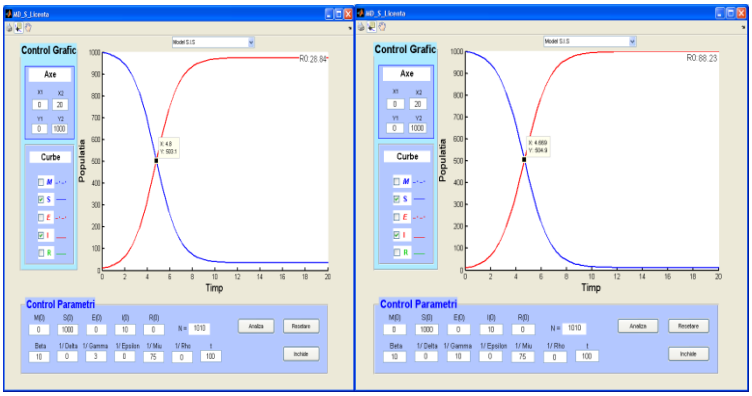

Fig. 6. SIS model analysis a. (up) $\beta = 10$ and $\frac{1}{\gamma} = 3$; b. (down) $\beta = 10$ and $\frac{1}{\gamma} = 10$;

The lack of susceptible individuals slows the epidemic when there are many infective individuals; and many susceptible individuals increase the spread of the epidemic when there are few infective individuals. Because an epidemic usually begins with a small set of infected individuals, let us choose this value to I_0.

CONCLUSIONS

Infectious diseases have always been a fierce opponent. In our study, the use of a graphical user interface provides a much easier interaction with the computer, simplifies the structure of complex instructions, using icons and menus. To prevent and control their spread, numerical and mathematical modeling of epidemic dynamics has played an essential part in investigating their transmission, estimating key parameters from the data published by the departments of health, understanding the characteristics of transmission and implementing prevention and control measures. Using the graphical user interface suggested by this paper, detailed calculation experiments may be carried out, that may help planning the response of authorities in case of a pandemic situation. I have not considered a mathematical model to represent a specific disease in this paper, because my main objective was to demonstrate the idea that the infection transmission can easily be studied using graphical user interfaces.

PLANT-DERIVED ANTICANCER AGENTS. CURCUMIN IN CANCER PREVENTION AND TREATMENT (Abstract): Nowadays cancer is still a major public health issue. Despite all the progresses made in cancer prevention, diagnosis and treatment, mortality by cancer is on the second place after the one caused by cardiovascular diseases. The high mortality and the increasing incidence of certain cancers (lung, prostate, colorectal) justify a growing interest for the identification of new pharmacological agents efficient in cancer prevention and treatment. In the last fifty years many plant-derived agents (vinblastine, vincristine, vindesine, paclitaxel, docetaxel, topotecan, irinotecan, elliptinium) played a major role in cancer treatment. Other very promising plant-derived anticancer agents (combrestatins, betulinic acid, roscovitine, purvalanols, indirubins) are in clinical or preclinical trials. Curcumin, a liposoluble polyphenolic pigment isolated from the rhizomes of *Curcuma longa* L. (*Zingiberaceae*), is another potential candidate for new anticancer drug development. Curcumin has been reported to influence many cell-signaling pathways involved in tumor initiation and proliferation. Curcumin inhibits COX-2 activity, cyclin D1 and MMPs overexpresion, NF-kB, STAT and TNF-alpha signaling pathways and regulates the expression of p53 tumor suppressing gene. Curcumin is well-tolerated but has a reduced systemic bioavailability. Polycurcumins (PCurc 8) and curcumin encapsulated in biodegradable polymeric nanoparticles (NanoCurc) showed higher bioavailability than curcumin together with a significant tumor growth inhibition in both *in vitro* and *in vivo* studies. **Keywords:** ANTICANCER AGENTS, PHYTOCHEMICALS**,** CURCUMIN, MOLECULAR TARGETS, BIOAVAILABILITY.

At the beginning of the 21st century, cancer is still a major global public health issue. Recent statistics show that cancer is the second-leading cause of death after cardiovascular diseases. But it is the first most frequent cause of death in 45-65 years old people including a high percentage of working population. The most common cancers in term of incidence are the lung, breast and colorectal cancers. Cancer incidence is supposed to increase dramatically in the next years. In these circumstances, cancer is a research priority in understanding its basic mechanisms, identification of early diagnostic methods and especially in development of efficient treatment methods. In recent years, interest for anticancer drugs with high efficiency and good tolera-

bility has increased and it will probably continue to increase in the near future (1, 2).

PHYTOCHEMICALS IN CANCER TREATMENT

In the last fifty years many plant-derived agents played a significant role in cancer chemotherapy. Numerous phytochemicals with antitumor activity have been isolated from plants. Only few advanced into clinical use; most of them served as prototype chemical structures for semisynthesis and synthesis of more potent analogues (3).

The first plant-derived anticancer agents in clinical use were vinblastine and vincristine, bisindole alkaloids isolated from *Catharanthus roseus* G. Don. sin. *Vinca rosea* L. (*Apocynaceae*). Vinblastine, vincristine, semisynthetic derivatives of vinblastine (vinorelbine, vindesine) block mitosis in metaphase leading to apoptosis. They bind to microtubule ends suppressing their dynamics which is essential for chromosomes movements to the two poles of the mitotic spindle. Vinblastine (Velbe®), vincristine (Oncovin®), vinorelbine (Navelbine®) and vindesine (Eldisine®) are used in the treatment of leukemias, lymphomas, advanced testicular, breast and lung cancers, Kaposi's sarcoma (3, 4, 5).

Podophyllotoxin, an aryltetralin lignan, was first isolated from *Podophyllum peltatum* L. (*Berberidaceae*). Later on, it was isolated from other *Podophyllum* species (*P. emodi* Wall sin. *P. hexandrum* Royle, *P. pleianthum* Hance).

Podophyllotoxin blocks polymerization of tubulin and mitotic spindle assembly arresting mitosis in metaphase. All trials regarding clinical uses of podophyllotoxin failed because its severe side effects (nausea, vomiting, damage of normal tissues). Therefore, extensive studies were carried out in order to obtain more potent and less toxic semisynthetic derivatives. These studies led to etoposide and teniposide, cyclic acetals of epipodophyllotoxin-glucoside.

Unlike podophyllotoxin, these derivatives irreversibly inhibit catalytic activity of DNA topoisomerase II. Etoposide and teniposide form stable complexes with DNA and topoisomerase II. These complexes induce irreversible breaks in single- and double-stranded DNA leading to cell death. Etoposide (Vepesid®, Etopophos®, Eposin®) and teniposide (Vumon®) are used in the treatment of lymphomas, acute leukaemia, small cell lung, testicular, ovarian and bladder cancers (3, 4, 6, 7).

Paclitaxel (taxol) is a polyoxygenated diterpenoid isolated from *Taxus brevifolia* Nutt. (*Taxaceae*, Pacific Yew) and other *Taxus* species (*T. wallichiana* Zucc.). Like other plant-derived antitumor agents, paclitaxel is a spindle poison. But its mechanism of action is completely different and unique. Paclitaxel stabilizes the microtubules supressing their depolymerization to tubulin. In addition, paclitaxel induces apoptosis by inactivating apoptosis stopping protein Bcl-2. Paclitaxel (Taxol®, Abraxane®) is used in refractory ovarian cancer, metastatic breast and lung cancer, Kaposi's sarcoma. Docetaxel, a semisynthetic analogue of paclitaxel, is more active than the latter. Docetaxel (Taxotere®) is used for the treatment of metastatic breast cancer and non-small cell lung cancer (3, 4, 6, 8).

Campthotecin is a quinoline alkaloid isolated from *Camptotheca acuminata* Decne (*Nyssaceae*), *Ophiorrhiza pumila* Champ. ex Benth. (*Rubiaceae*), *Mapia foetida* Miers. (*Acanthaceae*). Campthotecin selectively inhibits DNA topoisomerase I but it was

withdrawn from clinical trials due to its severe toxicity (nephrotoxicity, myelosuppression). Topotecan and irinotecan are the only semisynthetic analogues of camptothecin in clinical use. Both compounds are soluble in water and have the same mechanism of action as camptothecin: they bind covalently to topoisomerase I blocking the enzyme activity. Topotecan (Hycamtin®) is used for the treatment of ovarian cancer and small cell lung cancer while the major therapeutic indication for irinotecan (Camptosar®) is the treatment of colorectal cancer (3, 4, 6, 8).

Other plant-derived anticancer agents in clinical use are homoharingtonine and elliptinium. Homoharingtonine, an indole alkaloid from *Cephalotaxus harringtonia* var. *drupacea* (Sieb and Zucc.) (*Cephalotaxaceae*), induces apoptosis, tumor growth and metastasis by inhibiting tumor neoangiogenesis. Homoharingtonine (Ceflatonin®) is used in various leukemias, including those resistant to standard treatment. There have been reported cases of complete remission in patients with chronic myelogenous leukemia. Elliptinium is an ellipticine derivative, an indole alkaloid isolated from several genera of the *Apocynaceae* family, especially from *Bleekeria* genera (*Bleekeria vitensis* A. C. Sm.). It acts similar to alkylating agents by forming covalent linkages with DNA. Elliptinium (Celiptium®) is used in the treatment of breast cancer (3).

Numerous plant-derived anticancer agents are in the clinical and preclinical development; some of them proved to be very potent and might become anticancer drugs in the near future.

Combrestatins are compounds with different structures (bibenzyl, stilbene, phenantrene skeleton) isolated from *Combretum caffrum* (Eckl. & Zeyh.) Kuntze (*Combretaceae*).

The most active combrestatin, combrestatin A-4, is a stilbene derivative; it binds to beta-tubulin blocking microtubule and mitotic spindle assembly. Its phosphate, hydrosoluble, is now in phase II clinical trials in USA and Great Britain. Magnetic resonance imaging experiments showed that combrestatin A-4 phosphate reduces blood flow to tumor cells. In bioassays based on animal models a sodium phosphate derivative of combrestatin A-4 blocked blood supply in metastatic tumors leading to tumor necrosis. Numerous structural analogues of combrestatin A-4 have been synthetized; some of them are in clinical and preclinical trials (3, 4, 6).

A promising case is that of betulinic acid, a lupane-type pentacyclic triterpene, very common in many plants. Betulinic acid has selective cytotoxicity against several human melanoma cancer cell lines (MEL-1, MEL-2, MEL-4, B16). Betulinic acid induces apoptosis through multiple mechanisms: rapid increase in intracellular reactive oxygen species production, disruption of mitochondrial membrane potential, DNA fragmentation. Studies on its possible clinical use in topical and systemic formulations are in progress (3, 4, 9).

Many plant-derived anticancer agents, investigated in preclinical and clinical trials, are potent inhibitors of cyclin-dependent kinases. These enzymes play a key role in cell cycle regulation and their overexpression is associated with tumorigenesis. Important examples are roscovitine and purvalanols (synthetic analogues of olomucine, purinic derivative from cotyledons of radish, *Raphanus sativus* L., *Brassicaceae*), indirubins (bis-indoles from *Indigofera tinctoria* L., *Leguminosae* and their substituted derivatives) (3, 10).

CURCUMIN AND MOLECULAR TARGETS IN CANCER PREVENTION AND TREATMENT

In the last years, numerous studies reported that curcumin has a huge potential in cancer prevention and treatment. Curcumin, a polyphenol with a diferuloymethane skeleton, was first isolated from from the rhizome of *Curcuma longa* L. sin. *C. domestica* Valeton (*Zingiberaceae*), an Indian species commonly known as turmeric. The therapeutic potential of curcumin was investigated in numerous inflammatory, cardiovascular, neurodegenerative, immunologic and metabolic disorders. Besides, there are many reports on the capacity of curcumin to induce cell cycle arrest and apoptosis and reduce tumor invasion and angiogenesis. The mechanisms are numerous and complex involving modulation of both cell signaling pathways and enzymes activity (11-16).

The overexpression of COX-2 in different types of tumors has already been reported. In the hormone-dependent breast cancer, COX-2 stimulates aromatase activity increasing estrogen secretion. Curcumin inhibits COX-2 activity and consequently reduces estradiol secretion in patients with hormone-dependent breast cancer (12, 13).

In the malignant cells, the aberrant activity of the transcription factors induces not only the tumor progression but also the resistance of the tumor cells to chemotherapy and radiotherapy. Many of the tumor cells protect themselves against apoptosis *via* nuclear factor-kappa B (NF-kB), one of the main transcription factors that regulate the expression of many genes involved in inflammation, cell proliferation and survival. Curcumin blocks the degradation of the unit alpha of NF-kB inhibitor (IkB); thus NK-kB remains in a latent, inactive form in the cytoplasm being unable to enter the nucleus, bind to DNA and activate transcription (12, 13). In multiple myeloma, lymphomas, leukemias, certain solid tumors there has been reported an increased activity of the signal transducer and activator of transcription (STAT). STAT induces cell growth and proliferation by increasing the expression of Bcl-2 and Bcl-xl thus inhibiting the apoptosis. It is obvious that STAT modulation might be a possible approach in cancer therapy. Curcumin inhibits the phosphorylation of STAT3 thus blocking its translocation to the nucleus. Curcumin also inhibits STAT1 phosphorylation but not STAT5 phosphorylation (12, 14).

The p53 tumor suppressing gene acts as a transcription factor which activates the genes involved in the regulation of the cell cycle. In normal cells, it blocks the cell cycle in the G1/S phase until the DNA lesions are repaired. If the lesions are extensive and cannot be repaired, p53 initiates apoptosis. The mutations in the p53 gene represent the most frequent genetic modification seen in human cancers. In head and neck squamous cell carcinoma curcumin selectively induces apoptosis in the G2 phase of the cell cycle mainly by regulating the expression of p53 (13, 14).

Cyclin D1 is a nuclear protein involved in the cell cycle regulation. Cyclin D1 and the cyclin-dependent kinases Cdk4 and Cdk6 are responsible for the transition from the G1 phase to the S phase of the cell cycle. Cyclin D1 overexpression leads to the abnormal proliferation of the cells by shortening G1 phase. In tumor cells curcumin regulates the aberrant expression of Cyclin D1 and the activity of Cdk4 (13, 14).

The tumor transformation is often correlated with an abnormal activity of the growth factors, their receptors and signal-

ing pathways. The aberrant expression of the epidermal growth factor receptors (EGFR) was reported in numerous solid tumors, including colorectal cancer. By blocking the receptors of the epidermal growth factor (EGF) and vascular endothelial growth factor (VEGF), curcumin significantly inhibits the neoangiogenesis which allows tumor growth and metastasis (12).

Curcumin inhibits the tumor invasion and angiogenesis by inhibiting the matrix metalloproteinases (MMPs) overexpression. A significant growth in the synthesis of MMPs is correlated with an aggressive tumor development and a high metastatic potential. MMP-2 and MMP-9 have recorded a significant decrease in the prostate and breast cancer cells treated with curcumin. In the cell line Colo-205 curcumin reduced the activity of MMP-2. There was also reported a reduced degradation of the extracellular matrix that is strongly involved in the tumor dynamics (12, 14, 15).

The tumor necrosis factor (TNF) represents a family of proinflammatory cytokines playing a major role not only in inflammation but also in tumor initiation and proliferation. The proinflammatory effects of TNF are mainly due to its ability to activate NF–kB. TNF-alpha, a vital member of the TNF family, induces the phosphorylation and degradation of IkB; NF-kB is thus released from its cytoplasmic location being able to enter the nucleus and act as a transcription factor. Curcumin suppresses TNF-alpha signaling by inhibiting NF-kB translocation into the nucleus (12, 14).

The mitogen-activated protein kinases (MAPKs) signaling pathway is intensively studied as a possible target in cancer prevention and treatment. In human ovarian cancer cells resistant to cisplatin, curcumin induced apoptosis by modulating the activity of p38 MAPK, kinases involved in NF-kB activation (1).

CURCUMIN IN HUMAN STUDIES

The promising results in the phase I clinical studies regarding the effects of oral administration of curcumin in patients with pancreatic, cervical and cutaneous cancer supported the initiation of phase II studies in which curcumin proved high efficacy in patients with colorectal and pancreatic cancers (12, 15, 16).

In a phase II study, curcumin (8 g per day for 8 weeks) significantly reduced NF-kB, COX-2 and STAT3 expression in patients with pancreatic cancer. At the beginning of the study, most of the pacients had significant higher levels of these markers than those found in healthy volunteers. No toxic effects were recorded. Despite its limited absorption, curcumin was active in patients with pancreatic cancer (17).

In another study, 62 patients with cancerous lesions on some external organs (vulva, breast, skin) were treated topically with curcumin. There were reported a reduction of itching in almost all patients, a reduction of lesions in 10% of the patients and a reduction of exudates in 70% of the patients. An increase of local itching was reported in a single patient with scalp melanoma (12).

A prospective phase I clinical study on 23 patients with high-grade prostatic intraepithelial neoplasia revealed the safety and tolerance of a new plant-based supplement, Zyflamend®, one of its ingredients being curcumin. Zyflamend® was administered orally (780 mg x 3/day for 18 months) both as monotherapy and in combination with nutritional supplements (probiotics, multivitamins, green and white tea extracts, docosahexaenoic acid). The stand-

ard biomarkers and the prostate-specific antigen (PSA) were monitored every three days. At the end of the treatment, reduced values for the C reactive protein and NF-kB were determined in the serum. 40% of the patients showed a 25-50% reduction of PSA. Zyflamend® was well-tolerated by all the patients (17).

CURCUMIN TOLERANCE AND BIOAVAILABILITY

Clinical studies showed that the administration of high doses of curcumin (2-12 g/day) generated few side effects, mild nausea or diarrhea (15). However, curcumin has a reduced systemic bioavailability at oral administration (11). This reduced bioavailability is reflected in its inability to inhibit the pulmonary and mammary tumors in patients treated *per os* and intravenously. Curcumin is practically insoluble in water whereas in neutral and alkaline solutions its degradation occurs very quickly. Several potential transport systems were tested in order to increase the bioavailability of curcumin such as: nanoparticles, liposomes or conjugates with polyethilenglycol.

PCurc 8 is a polyacetal-based polycurcumin, soluble in water and stable under physiological conditions. *In vitro* studies on several cancer cell lines (SKOV-3, MCF-7, OVCAR-3) showed that PCurc 8 blocks the cell cycle in the G0/G1 transition phase or in the G1 phase mainly through a caspase-3 dependent pathway. *In vivo* studies also showed a remarkable tumor-inhibiting capacity of this polymer (18).

NanoCurc, curcumin encapsulated in biodegradable polymeric nanoparticles, has a high systemic bioavailability when compared to pure curcumin. Administration of NanoCurc in association with Gemcitabine determined a full regression of the metastases in orthotopic pancreatic cancer models. The inhibition of the tumor growth was accompanied by a reduction in the NF-kB activity and MMP-9 and cyclin D1 expression (19).

CONCLUSIONS

The capacity of curcumin to modulate numerous cell signaling pathways and to interact with different molecular targets proves the real therapeutic potential of this compound. Both *in vitro* and *in vivo* studies support the therapeutic value of curcumin. Further studies are needed to identify the analogues with high bioavailability and efficiency in cancer prevention and treatment.

EVALUATION OF CARDIAC PARAMETERS USING ELECTRICAL IMPEDANCE PLETHYSMOGRAPHY

C. Corciovă, M. Turnea, Daniela Matei, D. Andrițoi
University of Medicine and Pharmacy "Grigore T. Popa" – Iaşi
School of Medical Bioengineering

EVALUATION OF CARDIAC PARAMETERS USING ELECTRICAL IMPEDANCE PLETHYSMOGRAPHY (Abstract): Impedance plethysmography is a method for determining changes in body tissue volumes, based on the measurement of electric impedance at the body surface. Because it is a non-invasive and cost-effective method to measure and analyze hemodynamics, it would bring to physiologists very important diagnostic information for the continuous care of critical patients with hemodynamic disorders. **Methods:** This study aimed at acquiring non-invasively and at analyzing plethysmografic waves by measuring the electrical impedance. For measurements we built a device that was designed as an injection module with a microcontroller, a programmable waveform generator, and a voltage controlled current source which generates a sinusoidal pulse with adjustable frequency (10–200 kHz) and adjustable intensity. In output, the device delivers an analogical signal representing the variation of the impedance of the explored section. The acquisition of the bioimpedance signal on PC was made easier by the use of a National Instrument data acquisition device, the NI USB 6009. **Results:** The bioimpedance signal processing, the user interface and the display were managed by MATLAB. Sample impedance data for a test subject are presented. From the experimental results, it is shown that the proposed bioimpedance measuring system could provide good performance over the frequency range for central or peripheral territory. **Conclusion:** The clinical importance of these findings is that this method can measure vascular parameters noninvasively, continuously and more conveniently in humans. **Key words:** IMPEDANCE, MICROCONTROLLER, BLOOD FLOW, CARDIAC PARAMETERS, VOLTAGE CONTROLLED CURRENT SOURCE.

In biomedical engineering, the term of bioimpedance is used in order to describe the response of a living organism to an external electric current applied on it. This technique is used on humans and animals in order to measure certain parameters, such as the blood flow or organism composition. The accumulation of knowledge in bioimpedance field led to the development of devices for measuring the cardiac flow and the circulating blood volume in different territories. The biologic materials, such as blood and muscular tissue, are poor conductors, as compared to other materials classified as conductors, (for instance, copper), at the frequencies used in order to measure the physiologic activity ($f < 10^6$ Hz). At higher frequencies, these biological materials have resistive properties, and at high frequencies they behave as dielectrics. The interest frequencies in the physiologic activity assessment by impedance are, usu-

ally, comprised between 20 kHz and 200 kHz. In order to discharge of the influence of other physiologic activities, such as ECG, EEG, EMG and the inferior limit frequency is set at 20 kHz. At the same time, the injected currents' intensities should not exceed some milliamperes in order to avoid muscles and nerves' stimulation (1).

The human tissue has both resistive properties and capacitive ones. Nowadays, there are several attempts of equivalent electrical circuits in order to describe the electrical properties of the tissues. The most used attempt comprises three components. It can comprise two resistances and a condenser or two condensers and a resistor. Figure 1 (a) presents the serial equivalent bioimpedance circuit, formed of two resistances and a condenser.

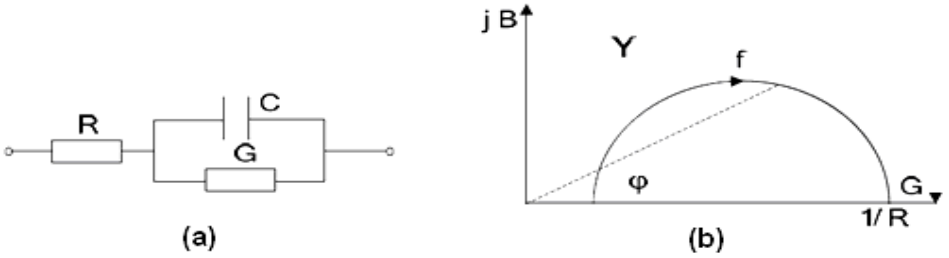

Fig. 1 The serial circuit 2R – 1C (a) and its response in frequency (b)

The circuit allows feeding in alternating current (DC) and current limitation at high frequencies. It is possible to obtain the same values for several frequencies for a single set of values of the components. The series circuit model characterizes the best tissue electrical impedance phenomenon, because the time parameter is uniquely defined (equations 1-7). This circuit was often used as an electrical equivalent of the skin, with resistance (R) representing the more profound series tissues with the skin formed of (G) and (C) in parallel. The response in frequency of this circuit is represented in figure 1 (b). The electrical model of the series circuit 2R-1C can be described by the following equations:

$$Z = R + \frac{G - j\omega C}{G^2 + \omega^2 C^2} \quad (1)$$

$$Z = R + \frac{1}{C(1 + j\omega\tau_z)}$$

$$\tau_z = \frac{C}{G} \quad (2)$$

$$\varphi = \arctan\left(\frac{\omega C}{G(1 + RG) + \omega^2 C^2 R}\right) \quad (3)$$

$$\varphi = \arctan\left(\frac{\omega C}{G(1 + RG + \omega^2 \tau_z \tau_2)}\right) \quad (4)$$

$$Y = \frac{G(1 + RG) + \omega^2 C^2 R + j\omega C}{(1 + RG)^2 + \omega^2 C^2 R^2}$$

$$Y = \frac{G(1+RG+\omega^2\tau_z\tau_2 + jw\tau_z)}{(1+RG)^2+(w\tau_2)^2} \quad (5)$$

$$\tau_2 = CR$$

$$C_{ext} = \varepsilon' = \frac{C}{(1+RG)^2+(\omega\tau_2)^2} \quad (6)$$

$$\varepsilon'' = \frac{G(1+RG+\omega^2\tau_z\tau_2)}{\omega[(1+RG)^2+(\omega\tau_2)^2]} \quad (7)$$

The impedance is the parameter which characterizes the two resistances and a condenser in series, because it is defined by a time parameter (τ_Z) (eq. 2). This time parameter is independent of (R) if the circuit was passed through by current. As a consequence, the impedance parameter has the advantage of measuring the characteristic frequency determined by (τ_Z) and is directly connected to the capacity (C) and conductance (G) connected in parallel (for instance, the membrane effect in tissues), unaffected by an access resistance.

MATERIAL AND METHODS

For the purpose of reducing the action areas derived from the stimulation electrodes and electrodes polarization itself, the technique adopted in the study is the method of the four electrodes. A pair of electrodes injects a constant current and variable frequency in the human tissue, and another pair of electrodes measures the potential difference between them (fig. 2) (3).

Figure 3 presents the block diagram of the proposed system of measuring the bioimpedance. It contains a microcontroller, a programmable wave generator and a source of current controlled in tension. Bioimpedance signal acquisition on a PC was performed by using a data acquisition device, USB NI 6009 from National Instruments. Located between the acquisition system and the PC, it ensures bioimpedance signal digitalization and its transfer on the PC for a subsequent processing.

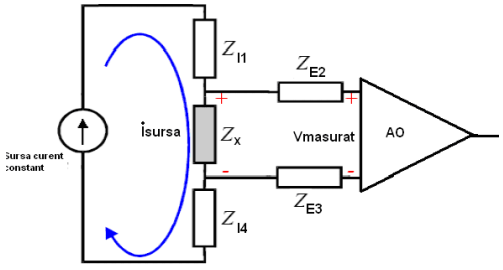

Fig. 2. The method of the four electrodes:
Z_{i1}, Z_{i4} – current injection electrodes;
Z_{E1}, Z_{E3} – signal collection electrodes

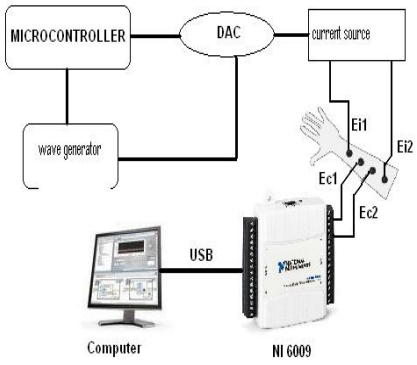

Fig. 3. Block diagram of the measuring system

The microcontroller employed belongs to MSP 430 class from Texas Instruments. They represent a family of microcontrollers with very low energy consumption, consisting of several circuit elements, which, interconnected among them, form different modules specific for medical applications. The microcontroller was modified in order to be fed from a 9 V battery too, for the purpose of being used also in portable monitoring applications.

The current sources are usually designed and produced using the following types of circuit: the mirror current type, feedback multi-operational and modified Howland circuit. The structure of the latter is very simple and has a high performance. The basic diagram of Howland designed circuit is presented in fig. 4.

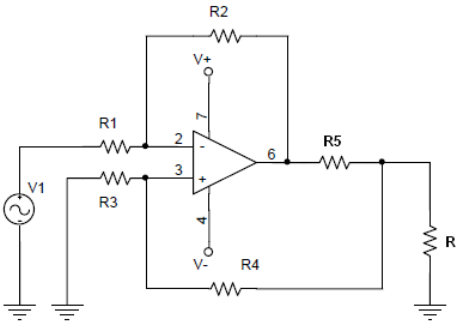

Fig. 4. Current source circuit diagram

After the practical achievement of the current source, a necessary condition is its calibration. In order to do so, resistor networks with tolerance of 1% were built. Networks with different values were tested (10 Ω, 150 Ω, 300 Ω, 510 Ω, 1000 Ω) and their impedance at discharge was measured for different frequencies.

Impedance signal acquisition on the PC was performed by using National Instrument data acquisition device, USB NI 6009. This card, placed between the equipment and the PC, ensures bioimpedance signal digitalization and its transfer to the PC for a subsequent processing. NI USB 6009 features: 8 analogical entrances (14-bit, 48 kS/s), 2 analogical discharges (12-bits, 150 S/s), 12 I/O digital; 32-bit counter, bus-powered for high mobility via the USB; signal connectivity. USB-6009 was configured and tested using MAX (Measurement and Automation Explorer).

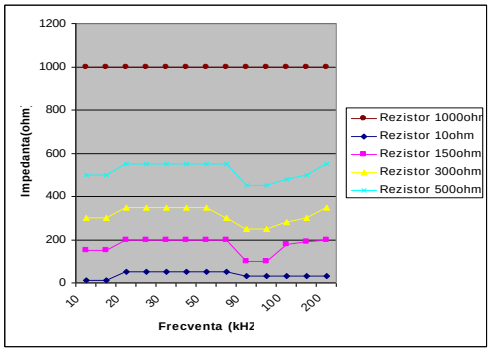

Fig. 5. System calibration – impedance variation for a calibration network value according to frequency

RESULTS AND DISCUSSION

The data analysis program was developed in MATLAB. It offers the opportunity of creating user interfaces by the Graphical User Interface Instrument GUIDE. The purpose of implementing the graphical user interface (GUI) in this project, was of obtaining programs more easy to use by means of certain visual elements associated with control actions and display actions as slides, buttons, menus, diagrams, etc. (5).

A graphical user interface offers to him a manner of interoperating very efficiently with all the elements coordinated by this environment. Its achievement requested the construction of a dendritic structure, based on two directions: one specific to the per-

sonal data associated to each patient, and the other associated to the analysis and determination of certain parameters specific to the plethysmographic waves.

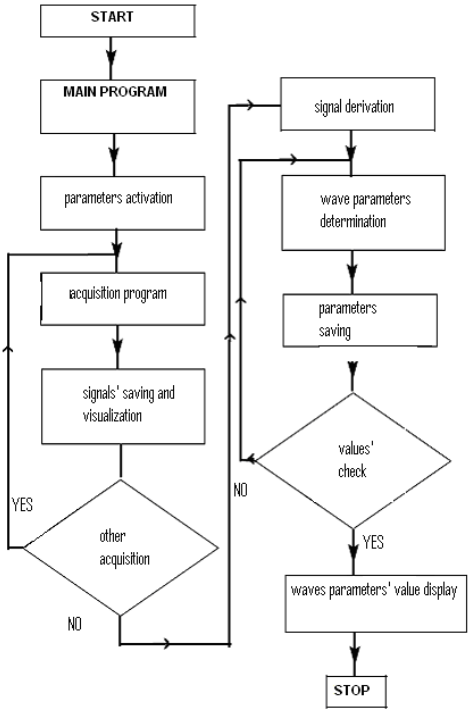

Fig. 6. Logical acquisition and processing diagram of the impedance signal

The total measured impedance Z (t) has three components: Z_0, $Z_R(t)$ and $Z_H(t)$. The component with the higher weight is the thoracic impedance Z_0, which reflects the electrical characteristics of the total thoracic mass (tissues, liquid and air). In a healthy man, Z_0 increases at about 25 Ω, and in a woman the values are, on an average, by 5 Ω higher. The second component, $Z_R(t)$, reflects the respiratory activity, which induces impedance changes of about 1 Ω. The third component, $Z_H(t)$, is synchronized with the cardiac cycle and reaches 0.10-0.15 Ω. As Z_0 does not modify in time, $Z_R(t)$ and $Z_H(t)$ determine together the modifications of the total thoracic impedance. The records were performed on 20 subjects, clinically normal. The values obtained at central level are presented in table I.

TABLE I

The average values of the central cardiac parameters

Parameter measured	Value
Cardiac rhythm (beats/min)	63.8±5.4
Beat volume (ml)	104.2±28
Pre-ejection period (ms)	125.7±9
Cardiac index	8.2±2
LVET (ms)	180±16

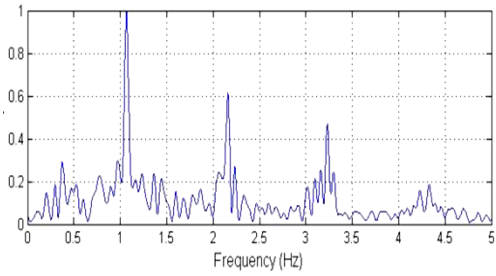

Fig. 7 The power specter of the plethysmografic signal

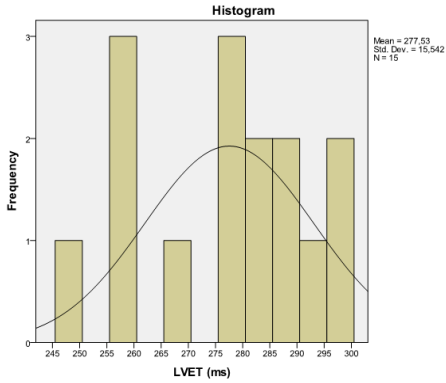

Fig. 8 Variable LVET distribution reported to the normal distribution for the studied group

CONCLUSIONS

The final solution chosen in the design and construction of the acquisition system of the electrical impedance signal proved to be viable and it corresponded from a technical point of view. The software used in calculating the central and peripheral vascular parameters was achieved by means of an accessible working environment.

The electrical impedance plethysmography is a technique which can be used on a wider scale for hemodynamic assessments. It can occupy an important place in assisting the physician in the diagnosis and continuous surveillance at patient's peripheral and central vascular level. Knowing the vascular modifications due to the use of heat and different cold modalities, physical exercises and walking can provide precious information on the circulating system subject to an effort. Determining vascular modifications associated with therapeutical modalities, vasoactive drugs and the disease conditions can offer useful orientations for a future treatment. The electrical impedance plethysmography technique has a high potential for the use in hospital and in the ambulatory, in patient care department, but also in research.

PATIENTS' SATISFACTION WITH CONVENTIONAL DENTURES AND MINI IMPLANT ANCHORED OVERDENTURES (**Abstract**): The aim of this study was to assess complete edentulous patient satisfaction with two treatment alternatives - conventional dentures and mini implant anchored overdentures. **Materials and methods**: Study sample comprised 36 patients - 18 treated with newly made conventional prosthesis and 18 with mini implants anchored overdentures, with a ball attachment system (from IMTEC Corporation). **Results:** Patients treated with mini implant anchored overdenture presented a higher satisfaction regarding chewing ability (all of them reported satisfactory mastication, 50% accusing occasionally discontent) compared with the conventional denture group (28% reported impaired masticatory function and 39% occasionally discontent). Denture's retention was better in the mini implant overdenture sample (only 17% reported occasional problems, none of them feel the need to use denture adhesives), compared to the conventional treatment alternative (28% were dissatisfied about this issue). Both treatment alternatives were seen as being highly satisfactory regarding the aesthetic restoration of facial appearance and for performing phonation. Still, in the complete denture group 22% of patients claimed difficulties in articulating certain phonemes. The main reasons why patients refused implant treatment were its higher cost and fear of surgery. **Conclusions:** Patients treated with mini implant anchored overdentures were more satisfied than those treated conventionally, due to the increased retention and stability of dentures, mastication efficiency and improved comfort, these having probably a positive effect on the quality of life. **Key words:** PATIENT SATISFACTION, DENTURE, OVERDENTURE, MINI IMPLANTS, MASTICATION.

According to World Health Organization, complete edentulism - as a result of loss of all teeth, treated with complete conventional denture - is a form of disability for most people, due to the reduced functionality and poor balance of the prosthesis (1, 2). Patient satisfaction with the prosthetic device depends on his/her ability to masticate, speak, and also on the aesthetic appearance after treatment. Berg and colleagues have shown that 66% of patients with conventional dentures were dissatis-

fied due to general discomfort, poor denture retention and chewing ability, and pain associated with wearing dentures, especially in the mandible. Even after making new dentures, 10 to 45% of patients were still dissatisfied with the treatment outcome in general, complaints related to prosthesis instability, mastication or aesthetics being present (3).

Currently, there is an increased interest for treatment alternatives indicated in complete edentulism - especially for implant supported ones. These are seen as modern and successful treatment options, indicated especially in high difficulty clinical cases, where there are lower odds to obtain a successful outcome by restoring the edentulous with conventional dentures (4). Although implant overdentures have become a first choice treatment for mandibular complete edentulism, as McGill Consensus states, still there are many clinical situations where the application of conventional implants is impossible without prior surgical interventions (e.g., bone split, bone addition) (5). Frequently, given the advanced age of patients, an associated systemic pathology is present, that may be related to a poor tolerability of surgical interventions.

Small diameter implants - called mini implants - can be a solution in many high difficulty edentulism cases, in which conventional implants have no applicability. There is a lack of scientific evidence regarding this treatment alternative, being present a limited number of longitudinal studies. The success rate reported by most authors exceeds 92.6%, on an observation period up to six years. Among the advantages of mini implant supported overdentures can be mentioned the minimally invasive characteristic of the technique, the immediate loading of implants, improved prosthetic device functionality and the reduced treatment cost (6-10). These are some of the reasons why, nowadays, this alternative presents an increased popularity.

The aim of this study was to assess complete edentulous patient satisfaction with two treatment alternatives - conventional dentures and mini implant anchored overdentures. Also, it was evaluated the perception of edentulous patient on implant anchored overdentures, as an alternative to the conventional treatment.

MATERIAL AND METHODS

At the Dental Prosthodontic Clinique, Department of Complete Denture, Faculty of Dental Medicine, Bucharest, an observational study was conducted on a group of 36 complete edentulous patients, seen from 2009 -2010. 21 were women and 15 were men, aged between 50 and 85 years. Of the 36 patients selected for study, 18 received conventional complete dentures and 18 mini implants anchored overdentures. The patients considered eligible to be included in the study were complete edentulous, with good oral hygiene, no local inflammatory processes or disorders of the oral mucosa, who had no general conditions to contraindicate surgery.

Conventional complete dentures were performed according to the current guidelines in this field. For implant overdentures, mini implants from the IMTEC Company were used – being applied a minimum of 4 in the lower jaw and 6 in the upper jaw. The mini implants used had different lengths (10, 13, 15, 18 mm) and diameters (1.8, 2.1, 2.4 mm). A ball attachment system was used, the implant being fitted with spherical crown portion. The complete denture pre-

sented a corresponding part - a metallic matrix with O-ring. The type of implant loading was chosen based on the quality of bone and insertion torque measured at the implant site. For values below 35 Ncm delayed loading of implants were used and over this value, the implants were loaded immediately (11-13).

One month after treatment's end, the patients were asked to complete a questionnaire, designed by the authors. The first part of the questionnaire recorded patient's personal data (name, address, age, educational level, and profession, occupation and life conditions), the reason for treatment request, personal and family history – systemic and local. The second part of the questionnaire evaluated patient's satisfaction with the old dentures, as well as with the newly ones - by questioning the level of dentures' retention, mastication ability, and comfort with dentures, phonation, and esthetics. The last part of the questionnaire contained questions used for evaluating patient's perception on dental implants, aspects regarding the financial possibilities and his/her interest in this treatment alternative.

RESULTS

Patients treated with mini implant anchored overdentures and conventional dentures presented similar characteristics (table I).

TABLE I

Characteristics of the patients

Variables		**Conventional dentures**	**Mini implant overdentures**
number of patients		18	18
Age	Mean	68.5	64
	Range	52-85	50-76
Sex	Male	6	9
	Female	12	9
Period of edentulousness	Upper Jaw	3-30 years	3-8 years
	Lower Jaw	3-30 years	6-15 years
Level of education	Low	8	6
	Medium	8	6
	High	2	6

In the conventional denture group, the main reasons of patient dissatisfaction with the previous prosthesis were the following: 33% of women and 50% of men reported problems in mastication and regarding the aesthetics; 17% mentioned denture's poor retention; 17% claimed the fracture of the prosthetic device; 16% accused phonation problems. Other complaints were related to teeth wear and deterioration of the material. The patients received a total of 32 dentures, of which 54% were maxillary and 46% mandibular dentures. After the application of newly made conventional dentures, an improvement in overall satisfaction with the prosthetic device related to aesthetics and mastication efficiency has been documented. Still, 28% reported masticatory deficiencies and retention problems, 17% frequently using denture adhesives. All

patients declared themselves satisfied with the aesthetics and with the restoration of the facial contours. 22% claimed difficulties in articulating certain phonemes (fig. 1). Perceived discontents were different according to sex, men being usually more satisfied. 67% of women and 83% of men reported no retention deficiencies. 25% of women and 50% of men reported a satisfactory mastication.

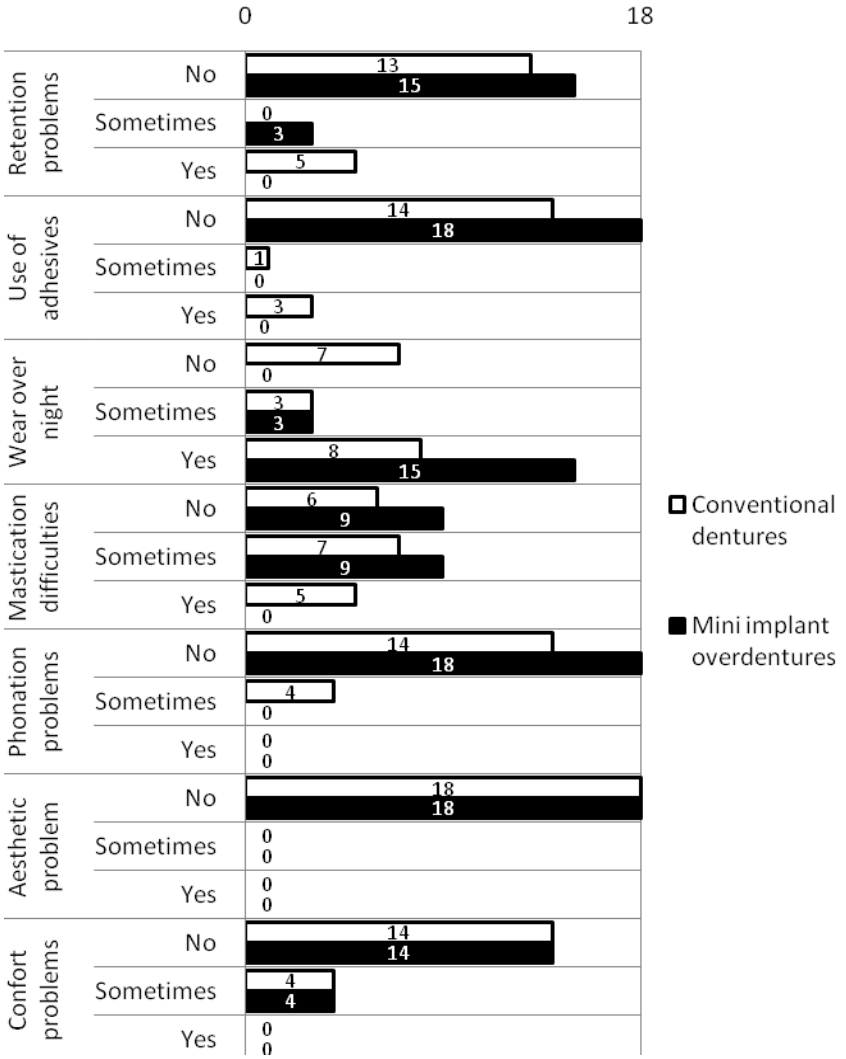

Fig. 1. Comparative assessment of newly made complete dentures and mini implant overdentures

In the mini implants anchored overdenture group, a total of 18 dentures (2 maxillary and 16 mandibulary) were fabricated. Within this group of patients, the main

dissatisfaction reasons with the old conventional dentures were related to poor retention and its stability. 100% of women and 75% of men reported difficulty during chewing. Other reasons were related to aesthetics problems, phonation, and dentures deterioration in time. With mini implant overdentures, an improvement of patient's perception regarding prosthesis's stability and chewing ability was noticed (fig. 1). Denture's retention was not considered a problem anymore by a rate of 89% of women and 78% of men, the rest showing only some occasional problems. Mastication was satisfactory for all patients, occasionally discontents being reported by 33% of women and 67% of men. The aesthetics, phonation and comfort have not been problematic for patients who were generally satisfied by these issues.

Regarding patients' perception on the use of dental implants, with the purpose of retaining conventional dentures, from the conventional denture group, women had a greater interest than men for the use of dental implants and mini implants (75% women compared to 67% men). From them 1 patient declared that he doesn't know about this treatment alternative (fig. 2). Among the main reasons why patients refused implant treatment were their high cost and fear of surgery.

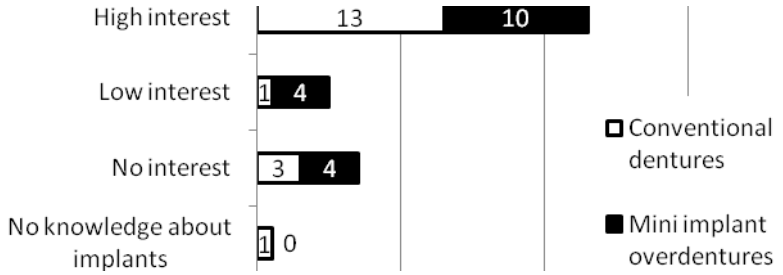

Fig. 2. Patients' perception and knowledge on implant supported overdentures

DISCUSSION

Implants supported overdenture treatment is considered beneficial especially for the patients who had persistent problems related to the retention and stability of conventional dentures, especially in the lower jaw. This treatment alternative favors an improved patient satisfaction with the prosthetic device, however, being quite restrictive in terms of cost, but also in terms of local and general clinical features cannot be considered a routine treatment for all complete edentulous patients.

In literature, studies have reported an overall patient's satisfaction with conventional dentures of 34%, comparing with 60% in patients with overdenture treatment. In the current study, the results are similar, both groups of patients reporting improved functionality with dentures, considerably higher in mini implants overdenture group. Patients with lower levels of education and lower income were more satisfied with chewing ability, aesthetics of denture, and phonation in both groups studied. This may be the consequence of the fact that these patients had lower expectations regarding treatment outcome. Patients who experienced many problems in previous treatments showed more dissatisfaction with the

current prosthesis, unlike those who considered previous prosthesis as being satisfactory. Patients' age influenced the ability to adjust to the dentures - older patients on their first prosthesis reporting more difficulties in adapting compared to the youngest ones.

The improvement in masticatory function is the main benefit brought by the use of implant therapy for edentulous patients. According to literature data, only 15% of patients treated with conventional denture are able to chew harder foods in comparison with a percentage of 88% to 96% patients treated with implant overdenture (10). In our study, among patients with mini implant overdentures, mastication was generally seen as being satisfactory, only occasionally chewing discontent being reported. Patients receiving conventional treatment presented lower chewing ability, being higher in male than in women. In terms of improving social life, patients among overdenture group reported an improvement - retention not being seen as a problem, adhesives not being used at all.

In general, edentulous patients from our sample showed knowledge and increased interest regarding implant treatment alternative. Few patients showed little interest in implant treatment, the main reason being the fear of surgical intervention. Other reasons for refusal of implant treatment were the cost and the insufficient information about this alternative.

CONCLUSIONS

Conventional dentures performed correctly can provide a satisfactory treatment outcome for a large number of complete edentulous patients, treatment's success depending on a number of factors related especially to the doctor's and technician's experience, and to the local conditions and patient's behavior. Patients treated with mini implant anchored overdentures were more satisfied than those treated conventionally, due to the increased retention and stability of dentures, mastication efficiency and better physical comfort. Although the cost of the implant prosthesis is considered high by most patients, they begin to be aware and to understand the benefits of this treatment alternative. Mini implants anchored overdenture offers, beside a minimally invasive intervention, the possibility of immediate functionality, reducing time and cost, being indicated in older people with complete edentulism, especially in the lower jaw.

CONTRIBUTIONS TO THE CHEMICAL STUDY OF THE ESSENTIAL OIL ISOLATED FROM CORIANDER FRUITS (SANDRA CULTIVAR) **(**Abstract): *Coriandrum sativum* L. (*Apiaceae*) is a well known herb, native to the Mediterranean region, also intensively cultivated in Romania. The essential oil obtained from *Coriandri fructus* posseses antimicrobial, antioxidant and anxiolytic effects. Many parameters such as genetic and climatic factors or agronomical practices can influence the yield and composition of the volatile fraction. Plant density is an important factor for the microenvironment in coriander field. **Aim**: In order to study the effect of planting density on the yield of the essential oil and its composition, a bifactorial experiment was carried out on coriander plants (Sandra cultivar). **Material and method**: The experiment was performed with three plant densities on the row (0, 15 and 20 cm); the distance between plant rows was 12.5, 25 and 50 cm, respectively. So, it resulted nine experimental variants. The essential oils obtained by hydrodistillation from fruits have been characterized using gas chromatography and mass spectroscopy analysis (GC-MS). **Results**: The highest yield (7.9866 kg/ha) was obtained for the plants spaced at 20 cm in between and 25 cm row spacing. The highest content of monoterpene alcohols (50.96%) was obtained with 25 cm row spacing and plant spaced at 0 cm on the row. The main components in all oils were monoterpene alcohols (40.75% - 50.96%) and monoterpenes (32.43-38.44%). **Conclusion**: The essential oil of coriander fruits (Sandra cultivar) does not meet the requirements of the European Pharmacopoeia, especially concerning the content in linalool. Nevertheless, the high content in monoterpene alcohols and monoterpenes recommends the use of the essential oil as immunomodulatory, analgesic and anti-inflammatory agent in rheumatology and also as an antibacterial and antiviral agent. Consequently, the changes in yield and composition of the essential oil of Sandra coriander should be assesed during several periods of vegetation in order to conclude on its pharmaceutical quality. **Key words**: *CORIANDRUM SATIVUM* L., ESSENTIAL OIL, COMPOSITION, VARIABILITY.

Coriandrum sativum L. (*Apiaceae*) se cultivă pentru fructele bogate în ulei volatil, utilizându-se ca atare sau sub forma fracțiunii volatile în industria alimentară, în parfumerie şi pentru obținerea unor fitomedicamente sau suplimente alimentare.

Dependent de zona de proveniență şi cultură, uleiul volatil, constituit majoritar

din monoterpene, se regăseşte în fructe în proporţii ce variază de la 0.1% (India) la 1.7% (Norvegia) (1). Componentele majore la un ulei volatil de calitate sunt linaloolul (60%-80%), camforul şi α-pinenul (2, 3, 4).

Influenţa unor factori externi precum soiul, condiţiile pedoclimatice şi de cultură, au fost intens studiate în străinătate cu privire la acumularea uleiului volatil în fructe. La noi în ţară se cultivă în special două soiuri indigene omologate, şi anume soiurile Sandra şi Omagiu. Dacă în cercetările efectuate până în prezent pe cele două soiuri s-a urmărit îndeosebi randamentul la hectar al producţiei de fructe, compoziţia chimică a uleiului volatil nu a fost investigată după cunoştinţele noastre, mai ales în corelaţie cu condiţiile de cultură. Studiul de faţă prezintă rezultatele înregistrate la analiza chimică calitativă şi semicantitativă a uleiului volatil separat din coriandru, **soiul Sandra**.

MATERIAL ŞI METODE

A fost supus analizei uleiul volatil separat din fructele de coriandru Sandra, cultivat la SCDA Secuieni (Neamţ, România), în anul 2009, în cadrul unui experiment în care s-a urmărit influenţa spaţiului de nutriţie (fig. 1) asupra producţiei de ulei volatil şi a compoziţiei sale chimice.

Factorii de cultură investigaţi au fost:

- distanţa între rânduri: a=12.5 cm; b=25 cm; c=50 cm;

- distanţa între plante pe rând: a=nerărit (0 cm); b=15 cm; c=20 cm.

A B C

Fig. 1. *Coriandrum sativum* L., soiul Sandra: A- în faza de răsărire; B- rozetă de frunze; C- în faza de înflorire

S-au obţinut 9 variante experimentale codificate S1-S9, perioada de vegetaţie până la maturarea fructelor fiind de 122 zile.

Fructele recoltate la începutul lunii august au fost uscate şi supuse distilării cu vapori de apă, izolând în acest mod fracţiunea volatilă pentru care s-a determinat randamentul la extracţie. Compoziţia chimică a uleiului volatil a fost determinată prin gazcromatografie cuplată cu spectrometrie de masă (GC/MS), utilizând un **cromatograf de gaze** Agilent Technologies tip 7890A şi un **spectrometru de masă** Agilent tip 5975C. Pentru separarea componentelor s-a folosit o **coloană** DB-5MS (30 m x 0.25 mm x 0.25 µm). **Temperatura coloanei** a fost programată să crească cu rata de 10ºC/min de la 35°C până la 280°C, iar temperatura finală a fost menţinută pentru încă 7,5 minute. **Temperatura injectorului** a fost de 250°C, **rata de splitare** fiind de 50:1. **Faza mobilă** folosită a fost heliul (1mL/min). **Volumul injectat** a fost de 0.2 µL ulei volatil. În ceea ce priveşte spectrometrul de masă, **temperatura sursei** a fost de 230°C, iar **temperatura cva-**

drupolului de 150°C. Componentele separate au fost identificate prin compararea spectrelor obținute cu cele existente în Wiley Library.

REZULTATE ŞI DISCUȚII

La distilarea cu vapori de apă a materialului vegetal s-a stabilit randamentul de extracție, calculându-se producția în ulei volatil exprimată în kg/ha (tab. I).

TABELUL I

Producția de fructe de coriandru şi ulei volatil la hectar

Codificare	Producție fructe (kg/ha)	Ulei volatil, randament (ml/100 g fructe uscate)	Producție în ulei volatil (kg/ha)
S1	591.2	1.4	7.2008
S2	603.9	1.4	7.3555
S3	602.5	1.5	7.8626
S4	654.3	1.4	7.9694
S5	633.2	1.4	7.7124
S6	612.0	1.5	7.9866
S7	403.5	1.4	4.9146
S8	423.6	1.4	5.1594
S9	456.2	1.3	5.1596

Din tabel reiese faptul că soiul face parte din categoria coriandrului cu înaltă productivitate pentru ulei volatil, dar dacă luăm în considerare producția la hectar pentru fiecare variantă în parte, constatăm că S7-S9 (la care semănarea s-a făcut la 50 cm distanță între rânduri) furnizează cantități care nu depăşesc 5,16 kg, fapt care trebuie pus pe seama numărului redus de indivizi (deci şi de fructe)/unitatea de cultură (fig. 2).

Pentru a stabili calitatea uleiului volatil, am determinat prin GC/MS compoziția chimică calitativă şi cantitativă a celor 9 probe de coriandru, rezultatele fiind redate în tabelul II.

După cum reiese din tabel, compoziția chimică variază foarte mult, numărul cel mai mare de componente volatile fiind determinat pentru varianta S3 (44 componente), iar cel mai mic pentru S2 (35 componente), ceea ce nu înseamnă că prima ar fi din punct de vedere calitativ şi cea mai bună.

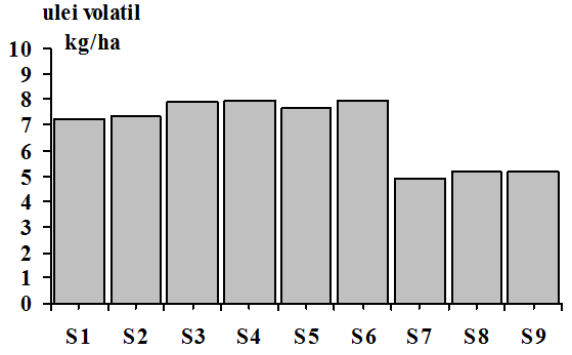

Fig. 2. Cantitatea de ulei volatil produsă/ha

Dacă ne referim la calitatea farmaceutică a fracțiunilor volatile separate din fructele celor nouă variante de coriandru Sandra, trebuie să urmărim cerințele Farmacopeei Europene ed. a 6-a, care impune o serie de limite (5) în cadrul monografiei *Coriandri aetheroleum*. Comparativ cu aceste cerințe, cele nouă uleiuri volatile au prezentat abateri, uneori importante (tab. III).

Din datele prezentate reiese clar că uleiurile volatile analizate conțin cantități insuficiente de linalool (41%-45%, față de minim 65%), în timp ce acetatul de geranil nu a putut fi cuantificat în nicio probă. Pe de altă parte, toate probele depăşesc valorile admise pentru α-pinen, γ-terpinen, p-cimen şi în măsură mai mică, pentru geraniol.

TABELUL III

Calitatea farmaceutică a uleiurilor volatile de coriandru (soiul Sandra)

Componentă	Cerință Ph. Eur. ed. a 6-a	Determinat (%)								
		S1	S2	S3	S4	S5	S6	S7	S8	S9
α-pinen	**3.0-7.0%**	10.66	12.89	9.76	10.58	9.46	9.42	10.43	9.45	8.97
limonen	**1.5-5.0%**	4.55	4.37	4.49	4.11	4.35	4.28	4.47	4.30	4.21

t-geraniol	**0.5-3.0%**	3.60	3.03	4.42	3.97	4.36	4.37	3.65	3.60	4.88

u= sub 0.01 %

Datorită acestor carențe, trebuie să tragem concluzia că uleiul de coriandru Sandra (producție 2009) nu întruneşte calitățile farmaceutice (deci terapeutice) cerute de

Farmacopeea Europeană, ediția a 6-a.

Grupând componentele identificate pe subgrupe de terpene, am obținut rezultatul redat în tabelul IV.

TABELUL IV

Compoziția chimică a uleiurilor volatile de coriandru pe subgrupe principale de compuşi

Grupă compuşi (%)	Aria (%)								
	S1	S2	S3	S4	S5	S6	S7	S8	S9
Hidrocarburi monoterpenice	36.81	38.44	34.90	33.91	34.33	33.67	36.32	32.43	32.97
Monoterpenoli	47.91	47.78	47.75	50.96	49.40	49.48	48.70	50.51	49.87
Monoterpencetone	5.88	5.32	5.85	5.74	5.99	6.16	5.73	5.94	6.23
Monoterpenaldehide	0.14	0.18	0.28	0.22	0.25	0.22	0.07	0.22	0.28
Monoterpenesteri	3.20	0.03	4.38	3.59	4.19	4.30	0.11	3.26	4.66
Total monoterpene	**93.94**	**91.75**	**93.16**	**94.42**	**94.16**	**93.83**	**90.93**	**92.36**	**94.01**
Sescviterpene	0.21	0.15	0.34	0.22	0.38	0.27	0.20	0.20	0.34
Compuşi alifatici	0.13	0.06	0.29	0.12	0.10	0.13	0.13	0.08	0.19
Compuşi aromatici	5.22	5.09	5.53	4.88	4.96	5.26	5.36	5.43	4.88

Urmărind valorile înscrise în tabel constatăm că din punct de vedere cantitativ predomină monoterpenolii (47,75%-50,96%), urmați fiind de hidrocarburile monoterpenice (32,43%-38,44%) şi, în mai mică măsură, de monoterpencetone (5,32%-6,23%), compuşi aromatici (4,88%-5,53%) şi monoterpenesteri (0,11%-4,66%). Dacă însă ne oprim atenția doar asupra celor două subgrupe majore de compuşi din compoziția uleiurilor de coriandru Sandra, constatăm că, adunate, ele reprezintă între 82.65% (S3) şi 86,22% (S2).

Din punct de vedere al acțiunii farmacologice, monoterpenolii (linalool, geraniol, 4-terpineol) reprezintă imunomodulatori eficienți, care protejează organismul mai ales față de situații de stres; acționează astfel armonizant asupra sistemelor hormonal, cardiac şi nervos, dermoregenerator, dar şi antibacterian şi antiviral, fără a distruge flora dermică normală. În plan psihic, sunt adaptogene, reglând producția hormonilor de stres, astfel încât calmează starea de agitație, relaxează psihic, cresc percepția pozitivă a mediului înconjurător şi dau senzația de armonizare cu acesta (6).

Pe de altă parte, hidrocarburile monoterpenice, puternic lipofile, penetrează rapid prin piele şi mucoase (inclusiv respirator), având o acțiune stimulant generală, analgezică, antiinflamatoare, iar la aplicare pe piele, blând contrairitantă. Mai ales α-pinenului i se datorează aceste din urmă efecte, din cauza modulării funcției corticosuprarenale. Limonenul, în schimb, pe lângă acțiunea antibacteriană şi antivirală, vine şi cu un efect imunostimulator. Datorită lor, uleiurile bogate în monoterpene reprezintă un tonic psihic, stimulând capacitatea de concentrare şi gândirea logică şi acționând anxiolitic.

CONCLUZII

Se pare că pentru o producție convenabilă de fructe, respectiv de ulei de coriandru, plantele au nevoie de un spațiu de nutriție adecvat. Cele mai bune rezultate s-au obținut, din acest punct de vedere, la

variantele de cultură S4 şi S6, pentru care spațiul între rânduri a fost de 25 cm, iar distanța între plante de 20 cm (S6), respectiv 0 cm (S4). Rărirea excesivă (S7-S9) nu asigură o bună exploatare a terenului agricol, producția de fructe şi deci, de ulei, fiind redusă.

Pentru coriandrul soiul Sandra cultivat la SCDA Secuieni în anul 2009, în condițiile menționate, chiar dacă producția de fructe şi ulei volatil este convenabilă, trebuie să apreciem că materialul vegetal recoltat nu corespunde cerințelor impuse de Farmacopeea Europeană ediția a 6-a, mai ales prin conținutul redus în linalool determinat în fracțiunea volatilă.

Cu toate acestea, având în vedere conținutul mare în monoterpenoli şi hidrocarburi monoterpenice, uleiul de coriandru soiul Sandra ar putea fi utilizat în preparate cu aplicare topică mai ales în reumatologie ca imunomodulator, antiinflamator şi analgetic, dar şi ca antibacterian şi antiviral.

Se impune repetarea studiului pe mai mulți ani de cultură, pentru a putea trage o concluzie finală şi a atenționa producătorii, dacă soiul se dovedeşte a nu corespunde cerințelor de calitate.

DENTAL TREATMENT STRATEGIES FOR ELDERLY PATIENTS (Abstract): The elderly are influenced from a various and complex combination of factors, such us individual genetic predispositions, lifestyle, society and environment. the sum of all the individual life experiences concerning the dental care, the caries, the periodontal and iatrogenic diseases. **Aim** : This paper evaluates the dental treatment in the elderly. **Material and methods** : The study was performed on 112 patients, aged over 65, at the Clinical Department of Dental Semiology und Geriatric Dentistry, Iaşi, Romania. **Results** : The treatment interventions were dental hygiene procedures (in 97 patients), restaurations (in 29 patients), removable partial and total denture preocedures (in 50 patients), fixed prosthetic procedures (in 18 patients), rebasing of dentures (in 25 patients) and teeth extractions (in 26 patients). There were 36 endodontic emergencies and 15 periodontal emergencies and 8 emergencies that resulted from other causes. **Conclusions** : The periodical dental examinations and the proper daily oral hygiene routine are still important in the old age and they should not be neglected, because the prosthetical components request also treatment interventions. **Key words** : ELDERLY PATIENT, DENTAL CARE, ORAL STATUS, DENTAL TREATMENT

Modificările survenite prin îmbătrânire influenţează tabloul clinic al unor îmbolnăviri şi fac dificilă culegerea informaţiilor, stabilirea diagnosticului şi a strategiei de tratament şi influenţează negative prognosticul (1).

În cazul îmbătrânirii fiziologice gradul de afectare a organelor este variabil, îmbătrânirea ca proces în sine poate fi evaluată după tipare diferite, în funcţie de corespondenţa ce se stabileşte între vârsta biologică şi vârsta cronologică (2,3).

Îmbătrânirea patologică se referă la îmbătrânirea fiziologică ce interferează cu fenomene patologice, fiind rezultatul acţiunii asupra organismului a unor factori de mediu extern sau intern care schimbă cursul normal al procesului de îmbătrânire (4).

Vârsta înaintată reprezintă prin ea însăşi un element de prognostic nefavorabil pentru pacient, dar acest lucru nu trebuie folosit ca argument împotriva unei examinări atente care să releve potenţialul şi riscul la care este supus pacientul respectiv (5,6).

În general nu există o patologie specifică vârstnicului dar întreaga patologie capătă o tentă caracteristică (6,7).

Scopul lucrării este de a evalua necesitatea, strategia şi răspunsul la tratament stomatologic la pacientul vârstnic.

MATERIAL ŞI METODĂ

Au fost examinaţi 112 pacienţi vârstnici cu vârste de peste 65 de ani, selectaţi dintre bolnavii care au solicitat asistenţă stomatologică în Serviciul Clinic de Semiologie Stomatologică şi Gerontostomatologie Iaşi.

Pacienţii luaţi în studiu au fost supuşi unui examen clinic atent, general şi local, completat de examene paraclinice: studiul de model, examen radiografic, etc, care ne-au permis stabilirea vârstei biologice care, raportată la cea cronologică, să permită stabilirea geroindexului general şi local care stă la baza succesului în practica geriatrică.

Doleanţele pacienţilor s-au raportat atât la dureri, cât şi la tulburări funcţionale. S-a insistat pe valoarea unei bune anamneze şi a unui examen obiectiv, urmărind ca primă etapă a evalua: starea generală, medicaţia, capacităţile psihice, capacităţile fizice, situaţia socială, starea generală.

Examenul clinic gerontologic a urmat acelaşi algoritm ca la adult, dar cu particularităţi de etapă specifice vârstei înaintate şi cu necesitatea consultului interdisciplinar.

S-a realizat anamneza afecţiunilor stomatologice, necesară pentru evaluare atitudinii pacientului în legătură cu tratamentele stomatologice şi motivaţia sa, precum şi o examinare atentă în vederea detectării unor eventuale afecţiuni ale mucoasei orale, modificări ale ocluziei, deviaţii de deschidere şi închidere.

S-a înregistrat şi schimbarea în starea de sănătate orală (ameliorare sau deteriorare), privind cariile şi condiţia parodontală, precum şi alte aspecte ale dentiţiei (dinti, proteze etc). Statusul cariilor a fost clasificat astfel: absenţa cariilor, carii fără implicare pulpară, carii cu implicare pulpară. Starea parodontală a fost clasificată prin scorul parodontal cel mai sever pe o scară după cum urmează: sănătate parodontală (absenţa modificărilor, sângerare la sondare, pungi parodontale ≥5,5 mm, mobilitate verticală (gr III) şi pungi purulente. O schimbare pozitivă în scorul celei mai severe stări a fost considerată o îmbunătăţire, iar o schimbare negativă a fost considerată o deteriorare a sănătăţii orale. Dacă nu a existat nicio modificare a celui mai căzut scor, s-a comparat numărul de dinţi cu cele mai grave scoruri, pentru a indica schimbările survenite între două evaluări de sănătate orală.

Terapia completă a disfuncţiilor sistemului stomatognat a necesitat un număr mare de tratamente odontale, parodontale şi protetice, grupate în urgenţe în caz de durere, paleative, tardive.

REZULTATE ŞI DISCUŢII

Din punct de vedere al repartiţiei pe grupe de vârstă se constată o preponderenţă a celor din grupa 65-75 ani faţă de cei din grupele 75-84 ani şi peste 85 ani (tab. I).

TABELUL I

Repartiţia cazurilor pe grupe de vârstă.

GRUPA DE VÂRSTĂ	NUMĂR CAZURI	PROCENT %
65-74 ANI	87	77,67%
75-84 ANI	14	12,50%
PESTE 85 ANI	11	9,83%
TOTAL	112	100,00%

În urma anamnezei amănunţite şi a examenului obiectiv s-a permis stabilirea unui bilanţ biologic şi a unui bilanţ nutriţional.

S-a evidenţiat o patologie generală, stabilindu-se un procentaj de patologie pentru fiecare grupă (tab. II).

TABELUL II

Repartiţia procentuală a bolnavilor pe grupe de vârstă şi de boală

AFECŢIUNI	GRUPURI DE VÂRSTĂ		
	65-74 ANI	75-84 ANI	PESTE 85 ANI
Boli cardiovasculare	40,9	41,8	46,9
Boli osteo-articulare	16,2	17,3	17,6
Boli metabolice	6,8	5,9	3,7
Boli ale SNC	9,7	11,3	10,9
Boli digestive	7,9	3,8	4,1
Boli ale sistemului respirator	8,1	6,9	5,9
Alte boli	19,1	11,9	12,01

S-a constatat depistarea multor afecţiuni neglijate de bolnavi şi s-a căutat orientarea conduitei terapeutice stomatologice.

Din considerente medicale, psihice (8) sau dentare, din cauza absenţei unităţilor masticatorii, a leziunilor odontale multiple, a bolii parodontale sau a protezărilor nefuncţionale, alimentaţia este necorespunzătoare, incompletă sau neechilibrată (9).

La examenul extraoral s-au observat modificări la nivelul feţei, traduse printr-o tendinţă de lăţire a feţei, datorită creşterii diametrului transversal (Zy-Zy) şi scăderea dimensiunii verticale a etajului inferior, datorată uzurii dentare necompensate prin erupţii, fie edentaţiei şi resorbţiei osoase (6,9). Reducerea texturii şi a elasticităţii buzelor se datorează modificărilor de vârstă la nivel muscular şi tegumentar.

Examenul oral prezintă edentaţii totale, iar pe arcadele dentare au mai rămas dinţi funcţionali. Scăderea numărului de dinţi restanţi pe bolnav, odată cu înaintarea în vârstă, arată că lipsa măsurilor profilactice la vârsta a III-a sunt definitorii pentru pierderea dinţilor, din cauza abandonului îngrijirii, în speranţa unei protezări mobile (10,11).

S-a constatat un număr mare de edentaţi total, protezaţi şi neprotezaţi, la ambele maxilare. Dintre aceştia, protezarea fusese realizată doar la 75% (tab. III, fig. 1).

TABELUL III

Statusul pacienţilor luaţi în studiu

Status	Nr. pacienţi
Dentiţie	
Edentaţe bimaxilară	54
Edentaţe unimaxilară	26
Proteze fixe (totală şi parţială)	59
Neprotezaţi	28
Protezaţi	84
Carii (pacienţi dentaţi)	
Fără carii	25
Carii simple	29
Carii complicate	31
Parodonţiu (pacienţi dentaţi)	
Sănătos	28
Sângerare gingivală	48
Pungi profunde	14
Pioree alveolară	7
Mobilitate gradul III	15

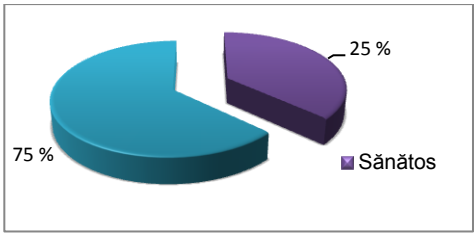

Fig. 1. Statusul pacienţilor luaţi în studiu protezaţi vs neprotezaţi

S-au remarcat diferite tipuri de leziuni carioase, o formă particulară fiind aceea cu localizare la nivelul coletului dinţilor, uneori cu evoluţie rapidă până la fractura dintelui (fig. 2). Pe lângă aceasta, la pacienţii dentaţi, se observă dispariţia treptată a stratului de smalţ, indicând fenomenul de exfoliere şi tendinţa modificării culorii smalţului dentar-cenuşiu. Din cauza periajului intempestiv, se produce în timp o pierdere de smalţ, observată mai adesea pe faţa vestibulară a caninilor şi a premolarilor.

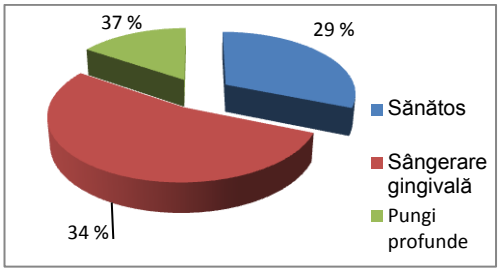

Fig. 2. Leziuni carioase la pacienţii luaţi în studiu

Când se păstrează mai mulţi dinţi restanţi pe arcadă, atriţia la vârstnic este cea mai importantă şi evidentă modificare a smalţului dentar legată de procesul de senescenţă, proces ce determină uzură ocluzală şi proximală a smalţului consecutiv contactului dento-dentar (12). Datorită solicitării funcţionale normale procesul de atriţie apare la toţi dinţii şi determină o micşorare a înălţimii coronare împreună cu aplatizarea conturului proximal, ducând la o reducere progresivă a volumului total al smalţului şi chiar a dentine, cu atingerea camerei pulpare (13,14).

Se observă fenomenul de abraziune sub forma unor faţete de uzură localizate pe suprafaţa obturaţiilor, a coroanelor de înveliş şi pe suprafaţa smalţului. Abrazia de tip patologic este frecventă, ca urmare a dezechilibrelor ocluzale, generate de iatrogenii, prin lipsa unor tratamente corecte, care să restabilească continuitatea arcadelor morfologic şi funcţional.

În cazul patologiei endodontice, s-au avut în vedere calcificările pulpare posibile puse pe seama tulburărilor metabolice prin carenţele vitaminice frecvente la vârstnici.

Boala parodontală la pacientul vârstnic are o evoluţie foarte lentă, cu absenţa fenomenelor dureroase, cu existenţa pungilor parodontale, a recesiunii gingivale şi mobilităţii dentare de diferite grade (3,5) (Fig. 3.

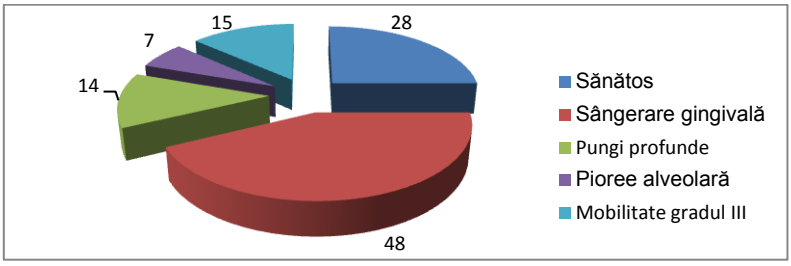

Fig. 3. Statusul parodontal al pacienţilor luaţi în studiu

Analiza clinică a pacienţilor vârstnici protezaţi şi neprotezaţi a pus în evidenţă afecţiuni ale parodonţiului, ale mucoasei orale şi unele disfuncţii ale articulaţiei temporo-mandibulare.

Tratamentul a cuprins manopere odontale, parodontale, protetice (tab. IV).

S-a ţinut cont de starea generală, evitându-se riscul şi temporizarea tratamentului până la echilibrarea constantelor biologice.

În cadrul afecţiunilor odonto-parodontale s-au urmărit eliminarea factorului microbian, creşterea rezistenţei gazdei şi reducerea substratului nutritiv disponibil pentru agenţii microbieni responsabili de apariţia afecţiunilor (15,16). Pentru îndepărtarea plăcii bacteriene s-au indicat metode chimice şi perioada aplicării în funcţie de limitele fizice ale pacientului. S-au realizat aplicaţii topice cu fluoruri, pentru creşterea rezistenţei ţesuturilor dentare la atacul acid, pentru favorizarea remineralizării în cazul leziunilor carioase incipiente şi pentru acţiunea împotriva plăcii bacteriene. Terapia odontală s-a realizat conservator prin tratament convenţional.

TABELUL IV

Tipuri de tratamente efectuate

Tipuri de tratamente efectuate	Nr pacienţi

Restaurări	29
Extracţii	26
Tratament protetic conjunct	18
Tratament protetic mobilizabil	50
Proteze totale (uni/bimaxilare)	18
Rebazare/optimizare proteze totale	25
Urgenţe stomatologie	
Endodontice	36
Parodontale	15
Altele	8

Specifice persoanelor în vârstă sunt gingivitele hiperplazice de cauză medicamentoasă, care de multe ori pot da naştere la false pungi parodontale prin hiperplazia marginii libere a gingiei, deşi epiteliul joncţional se găseşte la nivelul joncţiunii smalţ-cement şi nu se observă pierderi osoase (13,17).

Terapia parodontală efectuată a permis preîntâmpinarea apariţiei unei disfuncţii a sistemului stomatognat prin refacerea stării de sănătate parodontală, micşorarea sau dispariţia mobilităţii, limitarea fenomenelor de migrare dentară şi îndepărtarea planurilor înclinate traumatizante.

Tratamentul gnato-protetic a inclus pregătirea preprotetică şi proprotetică, bazate pe principiile punerii în condiţii optime a elementelor sistemului stomatognat, în raport de indicii clinico-biologici generali, loco-regionali şi locali (18,19).

Pentru instituirea unui tratament stomatologic individualizat bolnavilor vârstnici, este necesară cunoaşterea aprofundată a caracteristicilor bio-psiho-sociale şi spirituale ale acestei categorii.

Multe dintre bolile cronice pe care le prezintă vârstnicul cresc riscul aplicării tratamentului stomatologic sau chiar îl contraindică şi de aceea este foarte importantă colaborarea cu medicul generalist (10).

La diabetici există o prevalenţă mai mare a afecţiunilor stomatologice, de tipul candidozelor, uscăciunea neexplicată a cavităţii bucale, boli parodontale şi multiple carii (5,6).

Hemodializaţii şi cei cu transplant renal constituie un grup special care va fi tratat în strânsă colaborare cu specialistul nefrolog,

deoarece riscul intervenţiilor dentare este crescut (5,11).

Datorită dependenţei de medicaţie anticoagulantă, antiplachetară, antiinflamatorii nesteroidiene şi ticlopidine, mulţi dintre vârstnici au un risc crescut de sângerare (10, 11).

Îmbătrânirea oro-facială şi aspectul general constituie un index în aprecierea vârstei persoanei respective (4,5).

Odată cu înaintarea în vârstă apar modificări de culoare, de grosime ale tipului de dentină, care devine săracă în substanţe organice şi anorganice, căpătând un aspect translucid şi devine mai dură.

De asemenea, pulpa scade în volum, datorită formării în continuu de dentină secundară care reduce spaţiul pentru pulpă, care după 75 de ani poate fi complet obliterat.

Distrucţia parodontală se caracterizează prin pierderea ataşamentului periodontal şi reducerea înălţimii osului alveolar.

Bolile structurilor orale şi maxilo-faciale reprezintă circa 13% din totalitatea bolilor întâlnite la pacientul cu vârsta peste 65 de ani, când există o patologie specifică a sistemului stomatognat (11,14,21).

CONCLUZII

Datorită fragilităţii tisulare, a depresiei mecanismelor defensive şi a modificărilor morfo-funcţionale prin procese de involuţie patologia sistemului stomatognat prezintă un indice de gravitate crescut.

Diagnosticul geriatric necesită o cooperare interdisciplinară.

Variantele terapeutice vor fi raportate la prognosticul stării sistemului stomatognat.

Patologia orală întâlnită la pacientul vârstnic impune acordarea unei atenţii deosebite gerontoprevenţiei şi dispensărizării corecte prin controale periodice, în care se înlătură factorii nocivi, se corectează funcţiile şi se depistează leziunile într-un stadiu incipient.

STUDIES REGARDING CHEMICAL COMPOSITION OF LAVENDER VOLATILE OILS (Abstract): **Aim**: In this paper, we studied comparatively volatile fractions obtained by hydrodistillation from 5 samples of lavender flowers (*L. angustifolia* ssp. *angustifolia*, L. *hybrida*, *L. angustifolia* spp. p*yrenaica*, *L. angustifolia* spp. *angustifolia* cv. Munstead and cv. Hidcote blue) cultivated during 2009 in the Botanical Garden from Galati. **Material and methods**: The essential oils have been characterized using gas-chromatography and mass spectroscopy analysis (GC-MS). **Results**: The main compounds in all lavender volatile oils were: linalool (20.60%-35.99%), linalyl acetate (12.58%-19.65%), lavandulyl acetate (3.74%-10.48%), t-β-ocimene (1.26%-9.23%), α-terpineol (3.67%-6.73%), nerol (0.81%-3.32%), neryl acetate (0.95%-3.64%) and β-caryophyllene (0.93%-2.43%). **Conclusions**: None of the separated volatile fractions met the minimal quality parameters for the standard volatile oil of fine lavender used in aromatherapy. Low concentration in monoterpene esthers could be explained by the fact that, on one hand, the average daily temperature during the blooming period is below the one from Mediterranean Sea area, and, on the other hand, the city of Galati is only 42 meters above the sea level (the volatile oil from fine lavender used in aromatherapy is obtained from plants cultivated at 800-1200 meters altitude). **Key words**: ESSENTIAL OILS, *LAVANDULA*, CHEMICAL COMPOSITION

Genul *Lavandula* (*Lamiaceae*) cuprinde peste 30 de specii larg distribuite şi cultivate pe întreg globul pentru calităţile medicinale şi parfumistice ale inflorescenţelor lor.

Dintre acestea, oficinală este *Lavandula angustifolia* Miller (sinonim *L. vera* D.C, *L. angustifolia* Chaix ex Vill), care creşte spontan în întreg bazinul mediteraneean, dar se cultivă, mai ales în scopul extracţiei uleiului volatil, extrem de valoros, în Alpii Francezi (Provence), la altitudini de 800-1200 m, Spania, Maroc, Italia, Croaţia, Anglia, Tasmania şi Argentina, precum şi în România.

Şi alte trei specii de *Lavandula* sunt cultivate pe scară largă, în scopul separării, din inflorescenţe a uleiului volatil utilizat în aromaterapie: *L. stoechas* L., cunoscută ca rozmarin sfânt (Romero santo), *L. latifo-*

lia Medikus şi *L.hybrida* Rev. (*L.burnati* Briquet), foarte asemănatoare lavandei adevărate cu toate că este un hibrid între *L. angustifolia* şi *L. spica*, cunoscută sub denumirea de lavandină (1, 2).

Deoarece este cunoscut faptul că atât conținutul în ulei volatil, cât şi compoziția chimică variază mult de la o specie de lavandă la alta, precum şi în funcție de varietate, condiții pedoclimatice, altitudine sau metodă de extracție, ne-am propus în lucrarea de față să realizăm un studiu comparativ al fracțiunilor volatile separate prin hidrodistilare din florile unor specii şi varietăți de *Lavandula* cultivate la noi în țară şi interpretarea, în funcție de componentele identificate a eventualelor calități aromaterapeutice.

MATERIAL ŞI METODĂ

Materialul vegetal a fost constituit din flori de levănțică recoltate în iunie 2009 de la 2 subspecii de *Lavandula angustifolia* (ssp. *angustifolia* şi ssp. *pyrenaica*), 2 varietăți de cultură (*Lavandula angustifolia* ssp. *angustifolia* Munstead şi Hidcote blue), precum şi de la specia *Lavandula hybrida*, cultivate în Grădina Botanică Galați.

Izolarea şi determinarea cantitativă a fracțiunii volatile s-a realizat prin hidrodistilarea timp de 3 ore a materialului vegetal uscat, în aparatul Neo-Clevenger. Conținutul în ulei volatil al produsului vegetal s-a exprimat conform prevederilor Ph Eur. ed a 6-a, şi anume: mL ulei volatil la kg produs vegetal.

Compoziția chimică a uleiului volatil a fost stabilită prin analiza gaz-cromatografică cuplată cu spectrometrie de masă (GC-MS) în următoarele condiții: Gaz-cromatograf Agilent type 7890A; Spectrometru de masă Agilent 5975C; Coloană cromatografică DB-5MS (30 m x 0.25 mm x 0.25 μm); Faza mobilă: Heliu 1 mL/min; Temperatura injector 250ºC; Temperatura detector 280ºC; Regim de temperatură: inițial 35ºC, apoi creştere cu 10ºC/min. de la 35ºC la 280ºC (7.5 minute constant); Volum injectat: 0.2 μL ulei volatil. Rata de splitare: 1:100. Identificarea substanțelor din probele analizate gaz-cromatografic s-a făcut pe baza comparației între spectrul de masă şi spectrele din biblioteca Wiley.

REZULTATE ŞI DISCUȚII

Prin măsurarea volumului de ulei volatil rezultat la hidrodistilare s-a stabilit randamentul de extracție prezentat în tab. I.

TABELUL I

Conținutul în ulei volatil al probelor de *Lavandula*

Proba	Codificare	η (mL) în ulei volatil determinat/kg material vegetal uscat
L.angustifolia ssp. *angustifolia*	**LAA**	90.00
L.angustifolia ssp. *pyrenaica*	**LAP**	40.00
L.*hybrida*	**LAH**	30.00
L.angustifolia ssp. *angustifolia* Munstead	**LAM**	56.20
L.angustifolia ssp. *angustifolia* Hidcote blue	**LHB**	30.00

Concentrația în ulei volatil a probelor de lavandă variază între 30 şi 90 mL/kg produs vegetal uscat. Lavanda oficinală (*Lavandula angustifolia* ssp. *angustifolia*-LAA), precum şi cultivarul Munstead (LAM) sunt cele mai bogate în ulei volatil (90 şi respectiv, 56,20 mL /kg produs vegetal uscat), în timp ce *Lavandula hybrida* (LAH) şi varietatea Hidcote blue (LHB) au cel mai scăzut conținut (30 mL/kg produs vegetal). Toate probele de lavandă corespund cerințelor Ph Eur. ed. a 6-a (min. 13 ml ulei volatil/kg produs vegetal uscat), dar numai trei (LAA, LHB şi LAM) ar putea fi socotite că prelucrează *Lavandula angustifolia* Mill.

Analiza gaz-cromatografică a uleiurilor volatile obținute din florile de lavandă a demonstrat prezența unui număr mare de componente, acesta situându-se între 50 (proba LHB) şi 68 (proba LAP), reprezentând 92,90% şi respectiv 96,12% din totalul fracției volatile. Probele LAA, LAM şi LAH au un număr de 54, 61 şi respectiv 62 de componente, ceea ce constituie 91,99%, 91,66% şi 96,68% din total.

Cei mai importanți componenți identificați în uleiurile volatile analizate sunt redați în tab. II.

Componentele majore în toate probele sunt monoterpenele: linalool (20,60%-35,99%), acetat de linalil (12,58%-19,65%), acetat de lavandulil (3,74%-10,48%), t-β-ocimen (1,26%-9,23%), α-terpineol (3,67%-6,73%), nerol (0,81%-3,32%), acetat de neril (0,95%-3,64%) şi sescviterpena: β-cariofilen (0,93%-2,43%).

Grupând compuşii identificați pe categorii structurale, se obține compoziția chimică indicată în tabelul III.

În baza compoziției chimice uleiul volatil de lavandă se utilizează în fito- şi aromaterapie pentru calitățile sale antiinflamatoare, analgetice, spasmolitice, dezinfectante, febrifuge, imunostimulatoare, dermoregeneratoare, cicatrizante, tensioreglatoare, psihoechilibrante, anxiolitice, antidepresive şi sedativ/stimulante (1,3).

Prevederile standard în aromaterapie pentru uleiul de levănțică cer un conținut de 40-50% monoterpenesteri (componente principale acetat de linalil şi respectiv, lavandulil), 30-40% monoterpenoli (linalool), 7-13% monoterpene (ocimen) şi până la 8% sescviterpene (β-cariofilen) (1,4), dar în uleiurile volatile analizate se înregistrează următoarea situație:

- conținutul în monoterpenoli corespunde strict cerințelor doar în cazul lavandei oficinale (LAA) şi varietății sale de cultură Munstead (LAM);

- nivelul monoterpenesterilor este sub 40% în toate probele, fiind necorespunzător utilizării în aromaterapie;

- exceptând *Lavandula angustifolia* (LAA) şi *L. hybrida* (LAH), hidrocarburile monoterpenice cărora li se atribuie acțiunea tonic generală şi de creştere a capacității de concentrare, prezintă concentrații care se încadrează în standardul de aromaterapie; valorile mai ridicate pentru cele două probe menționate ar putea determina un efect antiinflamator şi analgezic mai pregnant prin reacția contrairitantă pe care o declanşează la aplicarea uleiurilor pe piele;

- varietatea de cultură Hidcote blue (LHB) a lavandei oficinale nu corespunde din punct de vedere al conținutului în sescviterpene, iar

- proba *L.angustifolia* ssp. *pyrenaica* (LAP) prezintă un conținut dublu în monoterpenoxizi față de valoarea standard;

- prezența cumarinei în probele LAP şi LAM impietează de asemenea utilizarea respectivelor uleiuri în aromaterapie.

Față de cele prezentate, trebuie să admitem că uleiul volatil separat din florile de *Lavandula hybrida* Rev. (care furnizează aşa-numita lavandină) şi *Lavandula angustifolia* ssp. *pyrenaica* se diferențiază de celelalte trei (LAA, LHB şi LAM), care se încadrează, conform definiției produsului, în categoria *L.angustifolia* Mill. Comparând uleiul de lavandină distilat din florile de *L. hybrida* Rev. de la Galați, cu datele cerute în aromaterapie pentru acest produs, vom constata din nou (1), că acesta nu corespunde prevederilor. Dacă uleiul de lavandină de uz terapeutic trebuie să aibă un conținut de 35-45% monoterpenesteri (preponderent acetat de linalil), 30-40% monoterpenoli (preponderent linalool), hidrocarburi monoterpenice 5-10%, monoterpencetone 4.5-5.5% (preponderent camforă), oxizi 2.5-3.5% (preponderent 1,8-cineol) şi 2% sescviterpene, concluzionăm că LAH corespunde în privința primelor două grupe de compuşi terpenici volatili, dar hidrocarburile monoterpenice sunt supradimensionate, iar cetonele, oxizii şi sescviterpenele, subdimensionate.

Dacă se urmăreşte **calitatea farmaceutică** a uleiului volatil obținut din florile de lavandă oficinală (*Lavandula angustifolia* ssp. *angustifolia*), ținând cont de prevederile specificate în Ph Eur. ed. a 6-a (5), se constată că nicio probă nu corespunde întrutotul din acest punct de vedere (tab. IV).

TABELUL IV

Calitatea farmaceutică a uleiului volatil obținut din probele de *L.angustifolia* ssp. *angustifolia*

Component (%)	Prevederi Ph Eur. ed. a 6-a	LAA	LHB	LAM
limonen	< 1	1.32	0.97	1.42
cineol	< 2.5	0.82	-	1.17
3-octanona	0.1-2.5	0.21	0.09	0.53
camfor	< 1.2	0.47	1.35	0.24
linalool	20-45	24.35	28.06	26.90
acetat de linalil	25-46	18.23	13.12	17.38
4-terpineol	0.1-6	-	2	3.75
acetat de lavandulil	> 0.2	3.74	9.46	8.42
lavandulol	> 0.1	-	0.80	1.46
α-terpineol	< 2	5.20	6.71	4.42

CONCLUZII

Fracțiunile volatile separate din cele 2 subspecii şi 2 varietăți de cultură ale speciei *Lavandula angustifolia*, precum şi de la specia *Lavandula hybrida* s-au dovedit a fi foarte diferite din punct de vedere chimic. Nici unul dintre uleiurile volatile de lavandă nu a prezentat toți parametrii de calitate impuşi pentru utilizarea în aromaterapie, cea mai importantă abatere fiind subdimensionarea conținutului în monoterpenesteri la circa 1/2-1/3 din valoarea standard. De asemenea, uleiul volatil din probele oficinale de lavandă nu corespunde întrutotul cerințelor de calitate impuse de ediția în vigoare a Farmacopeei Europene. Conținutul mic în esteri monoterpenici ar putea fi explicat prin faptul că temperatura medie zilnică în perioada de înflorire este mai mică în zona Galați-România prin comparație cu cea din zona mediteraneană. Totodată, orașul Galați este situat la o altitudine de 42 m deasupra nivelului mării, în timp ce uleiul de lavandă folosit în aromaterapie se obține de la plante cultivate la 800-1200 m deasupra nivelului mării. În aceste condiții, când începând cu data de 01.05.2011, Comunitatea Europeană impune respectarea condițiilor de admisibilitate a produselor vegetale de uz farmaceutic în funcție de alinierea lor la standardele europene, înainte de a le aduce pe piața farmaceutică, producătorii noştri de uleiuri volatile ar trebui să le controleze din punct de vedere chimic, chiar dacă ştiu sigur că au respectat prescripțiile privind proveniența botanică şi organul de plantă (menționat în definiție) în cursul prelucrării.

2. Institutul Naţional de Cercetare-Dezvoltare pentru Microbiologie şi Imunologie Cantacuzino Filiala Iaşi

CONSTRUCTION AND CHARACTERISATION OF A SELECTIVE MEMBRANE ELECTRODE FOR THE ASSAY OF LISINOPRIL (Abstract) : In order to analyze lisinopril using a selective membrane electrode, the electro-active compound was obtained and included in the selective membrane. The new analysis method was developed and validated. **Material and method** : The electro-active compound was obtained through the precipitation of lisinopril in acidic media using silicowolframic acid solution. The membrane was obtained by mixing the electro-active compound with polyvinylchloride using tetrahydrofurane as solvent. The solution was evaporated in order to obtain a thick membrane, which was then attached at one end of a polyvinylchloride tube. The internal Ag/AgCl reference electrode was inserted in that tube. The assembly was filled with a lisinopril internal solution. The electrode was characterized by establishing the following characteristics : electrode slope, selectivity, optimal pH range, response time and life-time period. The developed method was validated. **Results** : The method showed a good linearity in the range of 10^{-7} and 10^{-2}M (the correlation coefficient r = 0.9991). The detection limit (LD) was $8,66 \times 10^{-8}$M and the quantification limit (LQ) was $7,8 \times 10^{-7}$M. There were established the precision (RSD = 1.73%) and the accuracy (mean recovery was 99.92%) **Conclusions** : The experimental results demonstrated a good sensibility. **Key words** : LISINOPRIL, MEMBRANE-SELECTIVE ELECTRODE, POTENTIOMETRY, VALIDATION

Lisinoprilul face parte din clasa inhibitorilor enzimei de conversie a angiotensinei, fiind indicat în tratamentul hipertensiunii arteriale şi insuficienţei cardiace congestive.

Au fost obţinuţi şi studiaţi relativ puţini electrozi membrană selectivi pentru analiza compuşilor din această clasă, precum lisinoprilul, enalaprilul şi ramiprilul (1,2,3).

Lucrarea de faţă prezintă construcţia şi caracterizarea unui electrod membrană selectiv, precum şi metoda de determinare potenţiometrică a lisinoprilului ce foloseşte acest electrod (4,5,6).

MATERIAL ŞI METODĂ

Reactivi şi aparatură :

- soluţie apoasă, stoc de lisinopri10^{-2}M ;
- soluţii de lucru de concentraţii între 10^{-3} M şi 10^{-9}M obţinute prin diluţia cu apă distilată a soluţiei stoc de lisinopril ;
- soluţie internă de referinţă – soluţie de lisinopril 10^{-5}M preparată în soluţie saturată de AgCl ;
- soluţii tampon acetat pH = 4,0 şi 5,0 (7) ;
- soluţii apoase de KNO_3 0,01M, 0,1M, 1M, 1,5M ;

- electrod de calomel ;
- potenţiometru/pH-metru Hanna Instruments 300.

Sinteza complexului lisinopril-acid silicowolframic

La un volum de 20 mL soluţie apoasă de lisinopril 1% s-au adăugat 10 mL HCl 2 M, iar apoi în porţiuni mici şi sub agitare soluţia de acid silicowolframic 5% în exces, până la precipitarea completă. După un repaus de aproximativ o oră, precipitatul format a fost separat prin filtrare, folosind un creuzet filtrant G_4 şi a fost spălat cu o soluţie saturată de precipitat şi cu apă distilată. Precipitatul a fost uscat în exicator la vid, la temperatura camerei, până la masă constantă.

Prepararea membranei selective

O cantitate de 0,01 g complex lisinopril-acid silicowolframic s-a dizolvat în 6,2 g soluţie de clorură de polivinil 5% şi s-au adăugat 0,68 ml dioctilftalat cu rol de plastifiant. Din această soluţie s-au introdus 1,5 mL în interiorul unui inel din inox cu diametrul interior de 30 mm, aşezat pe o placă din sticlă şi lipit în exterior cu soluţie de polietilenă în tetrahidrofuran. După evaporarea solventului, în interiorul inelului a rămas o membrană polimerică ce a înglobat materialul electroactiv.

Construcţia electrodului membrană selectiv

Membrana obţinută s-a aplicat la capătul unui tub de policlorură de vinil utilizând ca adeziv soluţia de policlorură de vinil 5% în tetrahidrofuran şi s-a lăsat să se usuce timp de 24 de ore. În corpul electrodului cu membrana selectivă ataşată s-a introdus soluţia internă de referinţă în care a fost imersat un fir de Ag acoperit cu AgCl. Ca soluţie internă de referinţă s-a utilizat o soluţie de lisinopril de concentraţie 10^{-5}M realizată într-o soluţie saturată de clorură de argint, pentru a mări durata de viaţă a electrodului de referinţă intern prin reducerea solubilităţii clorurii de argint depusă pe firul de argint ce intră în construcţia electrodului membrană selectiv.

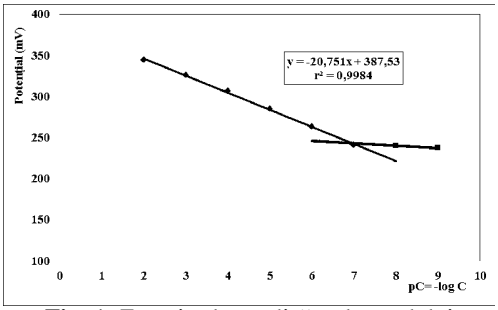

Fig. 1. Funcţia electrodică a electrodului lisinopril–selectiv

Caracteristicile funcţionale ale electrozilor membrană selectivi

Celula electrochimică formată din electrodul membrană ion–selectiv de construcţie proprie ca electrod indicator şi electrodul de calomel cu rol de electrod de referinţă extern a fost imersată în soluţia probei de analizat ce conţine lisinopril şi circuitul a fost închis cu ajutorul milivoltmetrului electronic cu rezistenţă internă mare (potenţiometru/pH-metru Hanna Instruments 300).

Efectul pH-ului s-a determinat prin măsurarea potenţialului la trei nivele de concentraţie : 10^{-2}, 10^{-4}, 10^{-7}M lisinopril ; modificarea pH-ului s-a realizat prin adăugare de soluţii tampon.

Influenţa tăriei ionice s–a studiat prin determinări pe seturi de soluţii de lisinopril, folosind soluţii de KNO_3 de diferite concentraţii pentru a ajusta tăria ionică. S-au comparat valorile pantelor dreptelor de calibrare obţinute prin metoda regresiei liniare şi s-a stabilit concentraţia soluţiei de KNO_3 ce a determinat o tărie ionică constantă pentru care panta a avut cea mai mare valoare.

Timpul de răspuns şi timpul de viaţă au fost evaluate prin înregistrarea valorile potenţialelor funcţie de timp.

Selectivitatea electrodului a fost testată din punctul de vedere al interferenţei ionii K^+, Na^+, CH_3COO^- şi NO_3^- deoarece aceştia au fost introduşi în soluţiile probelor de măsură în cazul ajustării pH-ului şi a tăriei ionice. Selectivitatea a fost apreciată prin coeficientul de selectivitate K.

TABELUL I
Valorile potenţialului de electrod pentru valori diferite ale tăriei ionice

pC = lgC	Soluţie KNO_3 0,01M	Soluţie KNO_3 0,1M	Soluţie KNO_3 1M	Soluţie KNO_3 1,5 M
2	310,6	321,9	344,6	344,1
3	295,4	303,5	326,4	326,7
4	280,2	287,6	307,2	306,4
5	265,6	270,3	290,1	289,4
6	250,7	253,9	264,3	263,6
7	235,6	236,3	240,8	240,2
Panta	**-14,96**	**-16,97**	**-20,64**	**-20,62**

TABELUL II
Valorile coeficienţilor de selectivitate calculate

Nr. crt.	Interferent	E(I)	E(II)	P	Coeficient de selectivitate, K
1	Na^+	306,8	136,2	20,75	$1,884 \cdot 1010^{-06}$
2	K^+		128,4		$1,031 \cdot 10^{-06}$
3	CH_3COO^-		115,5		$3,805 \cdot 10^{-07}$
5	NO_3^-		112,8		$3,088 \cdot 10^{-07}$

Funcţia electrodică a fost stabilită astfel: s-au efectuat măsurători de potenţial pe o serie de soluţii de lisinopril de concentraţie 10^{-9} până la 10^{-2}M. S-a trasat curba de calibrare a electrodului reprezentând potenţialul în funcţie de valoarea pC = – lg [lisinopril]. S-au determinat domeniul de răspuns liniar, panta electrodului şi potenţialul standard condiţional al electrodului.

Validarea metodei

Pentru determinarea liniarităţii s-au preparat, prin diluţii succesive cu apă distilată, soluţiile de lucru de concentraţii cuprinse în intervalul 10^{-2}–10^{-9}M. S-au citit valorile potenţialului folosind aceeaşi celulă electrochimică. Datele obţinute s-au prelucrat prin regresie matematică şi s-a trasat curba de calibrare. Metoda se consideră liniară dacă coeficientul de corelaţie este mai mare decât 0,998.

Precizia şi exactitatea au fost evaluate astfel: au fost analizate probe într-un domeniu de concentraţie de ±25% faţă de concentraţia de interes ce are valoarea de 10^{-4}M (10^{-3}M, 10^{-4}M, 10^{-5}M). În cazul preciziei se efectuează 2 seturi de probe pentru a evalua repetabilitatea metodei şi precizia intermediară. Pentru fiecare valoare a concentraţiei au fost efectuate un număr de trei determinări. Precizia şi exactitatea se exprimă prin deviaţia standard relativă (RSD) a valorilor obţinute care trebuie să fie mai mică de 2%.

Limitele de detecţie şi cuantificare s-au calculat utilizând metoda grafică (8,9,10).

REZULTATE ŞI DISCUŢII

Funcţia electrodică

Panta electrodului pentru domeniul liniar este P = –20,751 mV/decadă de concentraţie, iar potenţialul standard condiţional al electrodului determinat de pe curba de calibrare, prezentată în fig. 1, este $E_0' = + 387,53$ mV.

Influenţa tăriei ionice: valorile potenţialului de electrod înregistrate la diferite valori ale tăriei ionice sunt prezentate în tab. I.

Tăria ionică (constantă) pentru care panta a avut cea mai mare valoare s-a realizat prin adăugare de soluţie **KNO_3 1M**.

Efectul pH-ului: s-a stabilit că domeniul de pH optim este cuprins între 4,0 şi 5,0. Măsurătorile de potenţial pentru curba de calibrare şi determinarea potenţiometrică a lisinoprilului au fost efectuate după

TABELUL III
Liniaritatea metodei

Lisinopril pC = –lg C	Potenţial (mV)				
	Seria I	Seria II	Seria III	Seria IV	Media
2	343,5	342,6	344,6	345,1	343,95
3	326,6	325,2	326,1	325,9	325,95
4	305,2	306,6	305,4	306,8	306,00
5	285,8	286,4	284,9	286,5	285,90
6	264,2	266,2	265,2	267,0	265,65
7	240,7	243,2	242,3	241,4	241,90
Coeficient de corelaţie şi regresie **r = 0,9991, r^2 = 0,9983** Eroare standard = 1**,7298** Intercept = **386,3** Panta = **-20,32**					

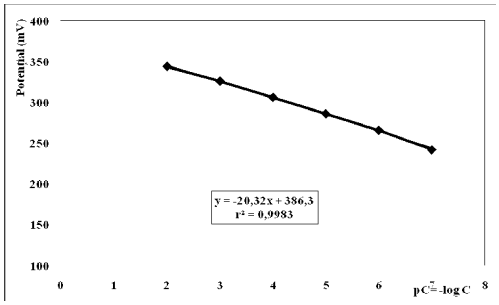

Fig. 2. Dreapta de calibrare

ajustarea valorii pH-ului la valoarea 4,0 prin adăugare de **soluţie tampon acid acetic-acetat de sodiu pH = 4,0.**

Timpul de răspuns este de aproximativ 15 secunde. Stabilitatea valorilor potenţialului de electrod este bună pentru o perioadă de aproximativ 2 luni, după care valoarea pantei electrodului începe să se modifice datorită degradării treptate a membranei selective.

Selectivitatea electrodului: valorile coeficienţilor de selectivitate sunt cuprinse în tab. II.

Valorile coeficientului de selectivitate, K, sunt foarte mici ceea ce indică că prezenţa ionilor testaţi în probe nu influenţează calitatea determinărilor.

Prin prisma acestor rezultate obţinute, procedura adoptată pentru determinarea cantitativă a lisinoprilului cu ajutorul noului electrod membrană selectiv a fost următoarea: din soluţia stoc de lisinopril 10^{-2}M se prepară prin diluţii succesive cu apă distilată soluţiile de lucru, de concentraţii în intervalul 10^{-3} - 10^{-7} M; din fiecare soluţie de lisinopril se măsoară un volum de 10 mL, se aduce în pahare Berzelius de 25 mL şi se adaugă un volum de 1,5 mL soluţie tampon pH = 4,0 şi 1,5 mL KNO_3 1M. Se citesc valorile potenţialului folosind electrodul de construcţie proprie şi electrodul de calomel (electrod de referinţă).

Validarea metodei

Liniaritatea metodei: s-a studiat liniaritatea pentru domeniul de concentraţie 10^{-7}–10^{-2}M. Datele obţinute sunt evaluate statistic (tab. III), iar prelucrarea acestora conduce la obţinerea dreptei de calibrare (fig. 2).

Domeniul de concentraţii în care electrodul prezintă un răspuns liniar este cuprins între **10^{-7} M şi 10^{-2} M**. Dreapta de calibrare calculată prin regresie matematică este:

$$\mathbf{E = -20,32 \times pC + 386,3}$$
$$\mathbf{(r^2 = 0,9983)}$$

Limita de detecţie şi Limita de cuantificare

Limita de detecţie are valoarea pC = 7,062 **($LD = 8,66 \times 10^{-8}$M)**

Limita de cuantificare are valoarea pC = 7,10 **($LC = 7,80 \times 10^{-8}$M)**

Precizia metodei: se constată că atât pentru fiecare set de date separat, cât şi pentru ambele seturi de date luate împreună, deviaţia standard relativă are o valoare mai mică de 2% (**RSD = 1,79%),** deci metoda de analiză este precisă (tab. IV)

Exactitatea: din valorile experimentale

TABELUL IV
Precizia şi exactitatea metodei

Conc. (mol/L)	Repetabilitatea metodei		Precizia intermediară		Exactitatea metodei	
	E (mV)	Regăsire %	E (mV)	Regăsire %	E (mV)	Regăsire %
10^{-3}	325,2	98,05	325,6	102,60	325,4	100,30
	325,5	101,44	325,2	98,05	325,3	99,17
	325,3	99,17	325,4	100,30	325,2	98,05
10^{-4}	305,1	100,54	305,3	102,85	305,0	99,41
	304,9	98,29	304,9	98,29	305,2	101,69
	305,3	102,85	305,1	100,54	305,1	100,54
10^{-5}	284,6	98,53	284,9	101,93	284,7	99,65
	284,8	100,79	284,7	99,65	284,6	98,53
	284,9	101,93	284,6	98,53	284,9	101,93
Date statistice	**Medie** = 100,17% **RSD** = 1,73%		**Medie** = 100,30% **RSD** = 1,84%		**Medie** = 99,92% **RSD** = 1,32%	

(tab. IV) se constată că pe domeniul de concentraţie studiat regăsirea medie este de 99,92%, iar deviaţia relativă standard (RSD = 1,32) este mai mică de 2% ; deci metoda de analiză propusă este exactă.

CONCLUZII

A fost construit şi caracterizat un electrod membrană selectiv ce utilizează ca material electroactiv complexul lisinopril-acid silicowolframic.

Electrodul membrană selectiv a fost caracterizat prin stabilirea funcţiei electrodice, efectul pH-ului, influenţa tăriei ionice, timpul de răspuns şi timpul de întrebuinţare, precum şi selectivitatea electrodului.

Metoda de analiză a fost validată, stabilindu-se : liniaritatea metodei (pe domeniul 10^{-2}M-10^{-7}M), coeficientul de corelaţie (r = 0,9991), limita de detecţie ($8{,}66\times10^{-8}$M), limita de cuantificare ($7{,}8\times10^{-8}$M), precizia metodei (RSD = 1,73%) şi exactitatea metodei (regăsire medie = 99,92%, RSD = 1,32%).

În concluzie, metoda de analiză propusă este simplă, uşor de executat şi sensibilă. De asemenea metoda este liniară, precisă şi exactă.

2. Departamentul de Protetică dentară

CLINICAL EVALUATION OF THE POSIBILITIES OF RESTORING THE DENTAL AND PERIODONTAL ESTHETICS USING VENEERS *VS.* METAL CERAMIC CROWNS (Abstract): Achiving the esthetic balance is one of the most important aims of the restorations used for the anterior area of the dental arches. **Aim**: To evaluate the posibilities of veneeers and metal ceramic crowns to restore dental and periodontal esthetics. **Material and method**: We have evaluated 90 restorations, 40 veneers and 50 metal ceramic crowns, analysing the following parametres: gingival index, bleeding index, palque index, also restorations margins index, presence/absence of secondary decays, marginal integrity index and the aspect of the rstorations surfaces. The study also evaluates patient staisfaction using questionares. **Results**: Even the veneers seem to be more indicated to restore dental and periodontal esthetics, the esthetic outcome depends mainly on the way the clinician evaluates and manages the tissues and less on the technique used (all ceramic or metal ceramic). **Key words**: VENEERS, METAL CERAMIC CROWNS, DENTAL ESTHETIC, PERIODONTAL ESTHETICS

Coroanele metalo-ceramice, deşi eficiente din punctul de vedere al refacerii funcţionalităţii unităţilor odonto-parodontale, prezintă o serie de dezavantaje cum ar fi necesitatea realizării unei preparaţii ce presupune îndepartarea unei cantităţi importante din structura dentară, necesitatea plasării subgingvale a marginii vestibulare ale preparaţiei atunci când se realizează la nivelul dinţilor arcului anterior maxilar, existenţa infrastructurii metalice care alterează capacitatea porţelanului de a reda translociditatea naturala a dinţilor şi uneori a culorii acestora. Faţetele ceramice rezolvă o serie dintre neajunsurile coroanelor de înveliş metalo-ceramice deoarece necesită preparaţii minime, de obicei doar la nivelul smalţului, permit refacerea morfologiei şi esteticii dentare, presupun amplasarea pragului preparaţiei la nivel supragingival, deci prezintă o serie de avantaje incotestabile. În aceeaşi masură însă indicaţiile lor trebuie stabilite cu discernământ, utilizarea lor fiind o varintă optimă doar în anumite cazuri, deci nu pot substitui sub nici o formă în totalitate coroanele de înveliş.

SCOPUL STUDIULUI

În cadrul acestui studiu ne-am propus realizarea unei comparaţii între coroanele de înveliş metalo- ceramice şi faţetele de porţelan din punctul de vedere al:

- Conservării stării de sănătate parodontală
- Capacităţii de resturare a echilibrului estetic
- Conservării rezultatelor în timp

MATERIAL ŞI METODĂ

Am evaluat astfel 90 de restaurări protetice, dintre care 40 au fost faţete de porţelan (grup I) şi 50 au fost coroane de înveliş metalo-ceramice (grup II).

Din grupul nr I au facut parte 8 barbaţi şi 12 femei cu vârste cuprinse între 27 şi 56 ani iar din grupul nr II au facut parte 10 barbaţi şi 15 femei, cu vârste cuprinse între 24 şi 62 ani.

Aceste două grupuri au fost divizate la rândul lor în subgrupuri în funcţie de vechimea restaurărilor protetice :

- Între 0 şi 6 luni
- Intre 7 luni şi 24 luni
- Mai vechi de 24 luni

Toţi pacienţii incluşi în studiu au fost selectaţi astfel încât să nu prezinte afecţiuni care să influenţeze starea de sănătate parodontală. Au fost astfel excluşi pacienţii care urmau tratamente cu ciclosporine, betablocante, anticoncepţionale, antiinfamatorii şi pacienţii cu afecţiuni cronice (ex : diabet). Am exclus din studiu pacienţii fumători.

În vederea evaluării stării de sănătate parodontala precum şi a gradului de refacere funcţională a unităţilor odonto-parodontale măsuratorile au fost efectuate de către 3 evaluatori. Aceştia au urmat acelaşi protocol de lucru şi au examinat aproximativ acelaşi număr de pacienţi. Calibrarea evaluatorilor a avut în vedere explicarea detaliată a protocolului de examinare cu realizarea unor determinări prealabile începerii studiului. Pentru calibare şi verificarea acurateţii/reproductibilităţii datelor s-au făcut şi evaluări încrucişate (fiecare evaluator a facut determinări la câte 6 pacienţi din celelalte loturi de studiu), concordanţa datelor culese având o rata de 97%.

Evaluarea stării de sănătate parodontală a presupus următoarele determinări :

- Investigarea profunzimii spaţiului biologic parodontal. Măsurarea s-a realizat după metoda clasică, în şase puncte : DV, V, MV, MP, P, DP.
- Determinarea indicelui de sângerare gingivală
- Determinarea indicelui de placă bacteriană

Pentru evaluarea profunzimii spaţiului biologic parodontal precum şi pentru determinarea indicelui de sângerare s-au utilizat sonde parodontale gradate . Determinarea indicelui de placă s-a realizat cu ajutorul revelatorilor de placa bacteriană.

Investigarea gradului de refacere funcţională a unităţilor odonto-parodontale a presupus analiza următorilor parametri :

- Indicele de localizare a marginilor restaurării protetice (1) :
- Prezenţa /absenţa cariilor secundare
- Gradul de integritate marginală a restaurărilor
- Aspectul suprafeţei restaurărilor protetice : structură, culoare, formă

Ultimii trei parametri au fost apreciaţi utilizând criteriile Ryge de evaluare clinică (2). Pentru acest parametru s-au luat în considerare numai suprafeţele vestibulare ale restaurărilor.

Pentru determinarea gradului de satisfacţie din punct de vedere estetic precum şi a gradului de confort, fiecare pacient a completat un chestionar unde a raspuns la următoarele întrebări :

1. Cum apreciaţi din punct de vedere estetic tratamentul protetic efectuat : 1- Excelent ; 2- Bun ; 3- Acceptabil ; 4- Inacceptabil
2. Cât de confortabile vi se par coroanele/faţetele realizate : 1- Excelent ; 2- Bun ; 3- Acceptabil ; 4- Inacceptabil

Datele au fost interpreatate din punct de vedere statistic utilizând teste t perechi, datele obţinute în cadrul celor două grupuri de studiu fiind analizate cu ajutorul testelor Krusall – Wallis. Pentru evaluarea modificărilor în timp din cadrul subgrupelor definite la nivelul celor două grupe de studiu am utilizat analiza de variabilitate a datelor.

REZULTATE

Am evaluat în total un nr de 90 de res-

TABELUL I

Rezultatele investigării stării de sănătate parodontală

Indice/tip de restaurare	Vestibular		Palatinal	
	Interproximal	Central	Interproximal	Central
Profunzimea spaţiului periodontal				
➢ FP	2,28	1,50	2,12	1,42
➢ CCM	2,52	1,67	2,48	1,73
Indicele de sângerare				
➢ FP	0,40	0,22	0,39	0,17
➢ CCM	0,64	0,25	0,77	0,60
Indicele de placă				
➢ FP	0,93	0,82	1,89	1,62
➢ CCM	0,89	0,75	0,48	0,25

taurări protetice, 40 de faţete de porţelan (FP) şi 50 de coroane de înveliş metalo--ceramice (CCM)

Pentru faţetele de porţelan vechimea medie a restaurărilor a fost următoarea :

0-6 luni : 2,6 luni

7-24 luni : 12,9 luni

< 24 luni : 35,5 luni

Pentru coroanele de înveliş metalo-ceramice vechimea medie a restaurărilor a fost următoarea :

0-6 luni : 2,5 luni

7-24 luni : 15,6 luni

< 24 luni : 38,7 luni

Rezultatele investigării stării de sănătate parodontală sunt prezentate în tabelul I.

Procentul situsurilor prezentând o profunzime a spaţiului periodontal mai mare de 3 mm a fost mai mic în cadrul lotului de faţete de porţelan. Frecvenţa pungilor parodontale de 4 mm a fost de 1% la nivelul suprafeţelor vestibulare ale faţetelor, de 4% în cazul feţelor vestibulare ale CCM şi de 2% în cazul faţelor palatinale ale CCM. Nu au existat diferenţe semnificative din punct de vedere statistic între determinările realizate la nivelul situsurilor apreciate la nivelul CCM şi cele evaluate la nivelul FP.

Indicele de sângerare a crescut proporţional cu creşterea indicelui de localizare a marginilor restaurării protetice (fig. 1,2).

Pentru fiecare grupa de indici (0-3) de localizare a marginilor restaurării, indicii de sângerare prezentau valor mai mari în cazul CCM decât în cazul FP.

Nu s-au constatat diferenţe semnificative din punctul de vedere al indicelui de sângerare între subgupele de vechime sau în cadrul aceleiaşi subgrupe de vechime.

Indicele de placă bacteriană a fost în general scăzut pentru faţa vestibulară şi nu a variat important statistic între cele doua grupuri de studiu. Înregistrarea indicelui de localizare a marginilor restaurării protetice a aratat ca 56 % dintre marginile FP au fost plasate juxtagingival iar 21% au fost plasate supragingival.

În cazul CCM 28% dintre marginile restaurărilor protetice au fost dispuse juxtagingival la nivelul feţei vestibulare în timp de 62% au fost plasate subgingval. La nivelul feţelor palatinale ale CCM, 31% dintre acestea erau dispuse juxtagingival şi 49% dispuse subgingival.

Evaluatorii au apreciat calitatea suprafeţelor restaurărilor protetice şi culoarea acestora ca fiind mai bună în cazul FP decât în cazul CCM în cazul restaurărilor incluse în grupa de vechime 0-6 luni (85%α vs 30%α) precum şi a celor incluse în grupa de vechime > 24 luni (75%α vs 35%α).

Nu s-au înregistrat diferenţe semnificative din punct de vedere statistic între cele două grupe de studiu în ceea ce priveşte capacitatea de restabilire a formelor şi contururilor, deşi 35% dintre coroanele analizate şi 32% dintre faţete erau supraconturate ca urmare a preparaţiei insuficiente.

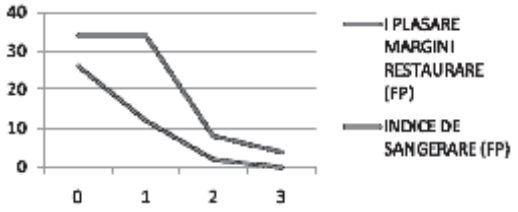

Fig. 1. Variaţia indicelui de sângerare în funcţie de indicele de plasare a marginilor restaurării protetice (FP)

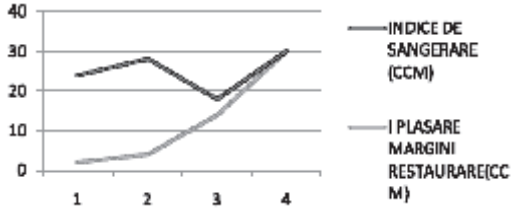

Fig. 2. Variaţia indicelui de sângerare în funcţie de indicele de plasare a marginilor restaurării protetice (CCM)

Nu s-au decelat fracturi nici în cadrul grupului FP nici în cadrul grupulu CCM.

Integritatea marginală a restaurărilor nu a diferit semnificativ din punct de vedere statistic între cele două loturi.

3 CCM au prezentat carii secundare (6%).

În ceea ce priveşte gradul de confort nu s-au înregistrat diferenţe semnificative, pacienţii apreciindu-l cu excelent şi bun. 80% dintre pacienţii incluşi în lotul cu FP cu o vechime mai mare de 24 de luni au apreciat ca excelent rezultatul estetic spre deosebire de 40% dintre pacienţii aceluiaşi subgrup dar trataţi cu CCM.

DISCUŢII

Succesul /eşecul diferitelor metode de restaurare a echilibrului estetic al unităţilor dento-parodontale depinde în cea mai mare măsură de maniera în care clinicianul gestionează suportul dento-parodontal, tehnologia în sine aleasă (integral ceramică sau metaloceramică) având un impact mult mai mic (3).

Studiile (4,5) arată că amplasamentul subgingival al marginilor restaurărilor protetice are efecte negative asupra stării de sănătate parodontală şi implicit asupra rezultatelor din punct de vedere estetic. În momentul în care clinicianul decide nivelul de amplasarea marginilor restaurării protetice trebuie să ia în calcul practic două aspecte :

- capacitatea de a menţine starea de sănătate parodontală
- plasarea marginilor restaurării să fie suficient de profundă dar în acelaşi timp să conserve dimensiunile spaţiului biologic parodontal.

Studiul a arătat creşterea proporţională a indicelui de sângerare în corelaţie cu indicele de plasare a marginilor restaurărilor protetice. Cu cât marginile restaurărilor protetice au fost lasate mai apropae de marginea gingivală liber cu atât riscul de apariţie a gingivitei a fost mai mare.

În aceeaşi măsură o altă cauză a alterării stării de sănătate parodontală a fost prepararea insuficientă a suprastructurii organice fapt care a condus la supraconturare atât în cazul faţetelor de porţelan cât şi în cazul coroanelor de înveliş.

În cadrul lotului de studu s-au constatat diferenţe semnificative între cele două loturi de studiu din punctul de vedere al recesiunii parodontale : 28% în cazul CCM faţă de 20% în cazul FP.

Din punctul de vedere al accentuării gradului de recesiune parodontală în timp , nu s-au înregistrat diferenţe semnificative între cele două loturi de studiu .

Determinarea profunzimii pungilor parodontale a relevat valori mai mari ale acestora în cazul CCM. Nu s-au înregistrat însă profunzimi mai mari de 4 nmm în nici unul dintre cele două loturi de studiu.

Din punctul de vedere al refacerii formelor, conturilor, culorii, structurii şi texturii suprafeţelor, rata de succes în cazul faţetelor de porţelan a fost mai mare decât în cazul coroanelor de înveliş metalo-ceramice (89% vs74%). Cauzele acestor rezultate sunt multiple.

Din punctul de vedere al formelor şi contururilor s-a constat o tendinţă mai mare a preparaţiei insuficiente în cazul coroanelor de înveliş fapt care a condus la restaurări supraconturate (6).

În aceeaşi măsură amplasarea coroanelor de înveliş metalo ceramice între structuri dentare naturale este un demers estetic mult mai dificil decât amplasamentul faţetelor integral ceramice, mai ales în cazul restaurărilor expuse integral iluminării directe cum sunt cele din zona arcului anterior maxilar (7). Existenţa infrastructurii metalice conduce la diferenţe decelabile vizual între gradul de transluciditate al dinţilor naturali şi suprastructurile protetice metalo-ceramice, fapt care conduce consecutiv la percepţia diferită a culorilor, formelor, contururilor şi chiar al texturii si structurii suprafeţelor restaurărilor. Acest deficit nu există în cazul faţetelor ceramice (8) .

Un alt motiv al alterării stării de suprafaţă este acela al ajustărilor realizate în cabinet la nivelul coroanelor de înveliş metalo-ceramice, fapt care a condus la alterarea stării de suprafaţă şi deci a luciului acesteia. Consecutiv se modifică comportamentul luminii la acest nivel şi deci percepţia culorilor, formelor şi dimensiunilor (9).

Deşi nu s-au determinat diferenţe importante din punct de vedere statistic între cele două loturi de studiu din punctul de vedere al integrităţii marginilor restaurărilor protetice, margile CCm par a fi mai suseptbile la carie secundară decât cele ale FP (5% faţă de 0%).

Din punctul de vedere al satisfacţiei pacienţilor faţetele de porţelan par a fi preferabile CCM. Acest fapt se poate datora pe de o parte rezultatelor estetice optime precum şi preparaţiei minim invazive şi faptului ca restaurarea nu ocupă decât faţa vestibulară a dinţilor.

CONCLUZII

Faţetele de porţelan par a avea, datorită exigenţelor de preparare şi avantajului pe care le prezintă datorită structurii integral ceramice, cel mai mic impact asupra stării de sănătate parodontală .

În acelaşi timp în cazul CCM cu cât marginea acestora se apropie de marginea gingivală liberă cu atât indicele de sângerare creşte şi este mai mare decât în cazul faţetelor de porţelan amplasate la acelaşi nivel.

CCM sunt mai susceptibile la carii secundare faţă de FP.

Potenţialul de refacere a formelor, dimensiunilor, culorii, structurii şi texturii suprafeţelor este mai mare în cazul faţetelor de porţelan, mai ales în cazul în care se are în vedere restaurarea incisivilor centrali maxilari. Amplasarea restaurărilor protetice între structuri dentare naturale face foarte dificilă crearea iluziei naturalului cu ajutorul CCM. De aceea este indicat ca în cazurile în care situaţia clinică permite să se prefere FP ca mijloc terapeutic.

Din punctul de vedere al satisfacţiei pacienţilor faţetele de porţelan par a fi preferabile CCM, diferenţa dintre cele două loturi de studiu fiind cu atât mai mare cu cât intervalul de timp creşte (80% satisfacţie în cazul FP la 24 luni faţă de 40% în cazul CCM).

NOUTĂŢI

EVALUAREA ALGORITMILOR FARMACOGENETICI PENTRU STABILIREA NECESARULUI DE WARFARINĂ ÎN CAZUL PACIENŢILOR JAPONEZI

Warfarina este unul dintre cele mai prescrise anticoagulante orale, folosită pentru profilaxia şi tratamentul bolilor tromboembolice. Stabilirea dozei necesare fiecărui pacient pentru a se încadra în intervalul terapeutic vizat, se face de regulă prin tatonare ; doza respectivă variind semnificativ de la un pacient la altul (de pana la 10 ori) în funcţie de vârstă, dietă, rasă şi genotip. Din aceasta cauză, cel puţin în primele luni de la începerea terapiei anticoagulante, pacienţii prezintă un risc crescut de anticoagulare excesivă ce poate duce la apariţia unor accidente hemoragice fatale. Pentru a se reduce cât mai mult posibil acest risc au fost elaboraţi o serie de algoritmi de dozare a acestui anticoagulant, majoritatea incluzând factori clinici, variabile demografice precum şi variaţii moleculare ale genelor implicate în realizarea efectelor warfarinei (VKORC1 – gena ce codifică subunitatea 1 a complexului vitamina K epoxid reductaza şi respectiv CYP2C9 – ce codifică enzima responsabilă de metabolizarea warfarinei). In anul 2007, FDA-ul a impus introducerea în prospectul warfarinei a informaţiilor relevante din punct de vedere farmacogenetic, iar recent, International Warfarin Pharmacogenetics Consortium (IWPC) a elaborat, în urma unui studiu la care au participat 5052 de pacienţi, un algoritm farmacogenetic de dozare a warfarinei : 5,4952–(0,2614 × [varsta în decade]) + (0,0087 × [înălţimea în cm]) + (0,0128 × [greutatea în kg]) – (0,8677 × [VKORC1 A/G]) – (1,6974 × [VKORC1 A/A]) – (0,9357 × [CYP2C9*1/*3]) – (2,3312×[CYP2C9*3/*3]) + (1,1816 × [statusul enzimatic]) – (0,5503 × [statusul amiodarona]) = radacină pătrată din doza săptămânală de warfarină. Performanţa acestui algoritm a fost testată de către cercetătorii japonezi utilizând 200 de pacienţi împărţiţi în 3 categorii : sub tratament cu doză scăzută de warfarină (≤10,5 mg/săptămână), sub tratament cu doză crescută de warfarină (≥31,5 mg/ săptămână), şi sub tratament cu doză intermediară de warfarină (între 10,5 şi 31,5 mg/ săptămână). Acest experiment a demonstrat reproductibilitatea performanţei algoritmilor IWPC în cazul celor 3 categorii de pacienţi japonezi, şi în mod special, în cazul pacienţilor sub tratament cu doză scăzută de warfarină (≤10,5 mg/săptămână), în cazul cărora procentajul supra-estimării dozei a fost semnificativ mai mic când doza de warfarină a fost stabilită folosindu-se algoritmul farmacogenetic (32%) decât ăn cazul folosirii algoritmului clinic (64%), reducându-se astfel semnificativ riscul anticoagulării (Takeuchi F, Kashida M, Okazaki O. Evaluation of pharmacogenetic algorithm for warfarin dose requirements in Japanes patients. *Circ J* 2010 ; 74 (5) : 977-982).

RESEARCHES OF THE NITRATES AND NITRITES IN SOME WELL WATERS FROM RURAL AREA IN CORRELATION WITH METHOGLOBINEMIA MORBIDITY (Abstract): Ground water is a major source of public supply for the rural population and in some areas, it is only source of available water. It is well known the toxic action of nitrate upon organisms, by formatting methemoglobin and N-nitroso compounds. **Material and methods**: In this study it was investigated the presence of nitrates and nitrites in same well waters, mountain and hill areas in Neamţ district. The chemical parameters were carried out by following standard methods. The statistical analysis includes descriptive statistics of the water quality parameters. **Results**: It is noticed high values of the nitrate concentrations, over Maximum Admissible Concentration (MAC), explained by excessive use of agricultural synthetic fertilizer and telluric nitrogen. It was registered a number of 38 cases of methemoglobinemia in small children with artificial nutrition, all cases from hill area. The maximum methemoglobin level was 60% and the minimum value of nitrate concentration in the water samples was 396 mg NO_3^-/L. **Conclusions**: We established a direct correlation between the level of methemoglobin and the nitrate concentrations in water samples. It is recommended the use well waters with maximum 48 mg/L nitrates content. **Key words**: WELL WATER, METHEMOGLOBINEMIA, NITRATES

OPTIMIZED METHOD FOR OBTAINING CHITOSAN NANOPARTICLES LOADED WITH XANTHINE DERIVATIVE

OPTIMIZED METHOD FOR OBTAINING CHITOSAN NANOPARTICLES LOADED WITH XANTHINE DERIVATIVE (Abstract): The use of nanotechnology is the current trend for drug delivery approaches. **Aim**: This research was focused on the development of an optimized method for preparation and characterization of chitosan nanoparticles (CSNPs) and xanthine derivative loaded CSNPs. **Materials and methods:** In order to develop appropriate method different parameters such as the concentration of chitosan and tripolyphosphate as well as the stirring speed were varied. The aggregation of the nanoparticles (NPs) was prevented by using Tween 80 as a surfactant. **Results:** Following the CSNPs optimization process nanoparticles in the range of 231-244 nm were obtained. The optimized method was used for the loading of xanthine derivative in the CSNPs. The particle size of CSNPs loaded with xanthine derivative was 267 nm and the loading efficiency was ~ 86%. In presence of the surfactant, the NPs size decreases slightly from 267 nm to 193 nm with increasing the concentration of Tween 80. The CSNPs loaded with xanthine derivative remain stable after 72 h of storage. **Conclusions:** The CSNPs and xanthine derivative loaded CSNPs obtained after the optimization method by modifying several independent variables can be characterized as having small size and a good stability over time. Given these important features CSNPs are promising materials for targeted drug delivery system. **Keywords:** NANOPARTICLES, IONIC GELATION, CHITOSAN, TRIPOLYPHOSPHATE.

Drug carrier systems constitute an important research field due to some characteristics such as the capacity to encapsulate bioactive compounds, cross biological barriers and to protect macromolecules such as proteins, peptides from degradation in biological media and to deliver drugs to a target site with following controlled release (1). Nanogels (nanometer sized hydrogel particles) have attracted growing interest over the last several years in terms of their potential for applications in pharmaceutical fields, like drug delivery systems for improve the pharmacokinetic profile of drugs such as poor gastro-intestinal absorption, low drug solubility, and rapid metabolism. In the last years have been important developments of several synthetic as well as natural polymers and has researched the possibility of their use for pharmaceutical applications (2).

Natural polymers can be generally divided into four different categories, including polysaccharides, proteins, nucleic acids, and lipids. One polysaccharides large used is chitosan (CS) and it is defined as polymeric carbohydrate structures composed of repeating monosaccharide units linked by glyosidic bonds (3).

Recently CS, the second most abundant natural polymer after cellulose, has attracted great attention in pharmaceutical and biomedical fields because of its advantageous biological properties such as: widely found in nature, biocompatibility, nontoxicity and biodegradability (4, 5). The manufacturing process of CS particles as carriers for drug delivery system, especially in terms of nanoparticles (NPs), has widely been studied (6). Several different techniques are usually employed to obtain NPs from CS including ionic gelation emulsion, synthesis with carboxymethyl cellulose, formulation using glutaraldehyde, synthesis with alginate and polymerization with poly (hydroxyethyl methacrylate). Among them the ionic gelation technique (IGT) has attracted considerable attention because it uses nontoxic cross-linker, organic solvent free and has convenient and controllable benefits (7, 8). IGT using syringe dropping is usually employed to prepare chitosan nanoparticles (CSNPs), in which sodium tripolyphosphate (TPP) solution (pH 7-9) was dropped into the acidic solution (pH 4-6) of CS. Despite of the easy procedures, it is uneasy to control the process for reproduction (9). The obtaining of CSNPs by IGT involve electrostatic interactions between the positively charged primary amino groups of chitosan and negatively charged groups of polyanions employed as cross-linkers to determined pH values, behaving as a metastable thermodynamic system which is highly sensitive to variations in ionic strength. For this reason appropriate choice of CS amount, the time spent in the reaction, the rate of addition and concentration of cross-linker agent TPP, the stirring speed applied during the reaction, pH of the solution are factors that affect the properties of CSNPs: particle size, long-term stability during storage, drug loading and release efficacy. It can be concluded that preparation process of CSNPs could be manipulated by varying the preparation conditions. TPP is the most frequently non-toxic polyanion used as cross-linker agent for preparation CSNPs (2).

It is know that NPs have a high tendency to aggregate after a storage period as a result of increasing the surface area in NPs formulations (10). During the preparation process of CSNPs the mechanical energy associated with the reaction stirring speed may exceed the electrostatic repulsion energy between nanoparticle positive surface charges, thus eventually triggering aggregation tendency. This represents a recurrent problem in the formation of single nanoparticles. Tween 80 decreases the surface tension at the interface between materials so this agent can be used mainly to limit aggregation of NPs and therefore acts in the reducing of their sizes (11). Therefore, developing CSNPS with small particle size is the key to improve its encapsulation efficacy and other functionalities.

This paper aims to describe the protocol for obtaining CSNPs in order to be used as drug delivery systems for xanthine derivatives.

MATERIAL AND METHODS

Materials. Chitosan low molecular weight (CSLMW), TPP and Tween 80 were purchased from Sigma Aldrich. Chitosan

had a molecular weight (M_w) of 190,000-375,000), viscosity of 200 cps and degree of deacetylation (DD) of 75-85% as indicated by the supplier. All other reagents and solvents were of high grade purity and were obtained from commercial suppliers.

Methods

Nanoparticles formulation

CSNPs were prepared *via* IGT proposed by Fabregas et al. (10). In order to optimize the method different concentrations of CSLMW – 0.05%, 0.1%, 0.25% w/v were chosen. Briefly, CSLMW was dispersed in acetic acid 2% (v/v) and the mixture was left under stirring overnight at room temperature to obtain clear CS gel. Then 2 mL of TPP aqueous solution (0.1% and 0.5%) were added drop wise to 0.25 mL CSLMW solution (0.05%, 0.1% and 0.25%) with a micropipette under 700 rpm and stirring speed of 1000 rpm. The conversion of the solution from clear to opaque appearance indicated nanoparticles formation. The final suspension was stirred for 2 h to obtain an efficient reticulation and then centrifuged. The NPs (sediment) could be observed from the bottom of centrifuge tube. The supernatant was removed and CSNPs were dispersed in distilled water for further characterization. The size and distribution of the CSNPs were monitored using a dynamic light scattering set-up equipped with a Brookhaven BI-9000 AT digital correlator (Brookhaven Instrum. Corp, N.Y.) at the temperature of 25^0C. For improving the CSNPs diameter and for avoiding the aggregation, the Tween 80 (10 μL and 20 μL) was added to a sample of 0.25 mL CSLMW gel (0.05%, 0.1% and 0.25% w/v) under stirring for 30 min. The particle size distribution was reported as polydispersity index (PDI) from the DLS analyzer, in which PDI <1 represented the good polydispersion (12). Particle size and polydispersity measurements were run in triplicate.

Chitosan nanoparticles loaded with xanthine derivative

The xanthine derivative (2-{2-[2-(1,3-dimethylxanthine-7-yl)acethyl]hydrazono}-5-benzylidene-3-(4-brom-phenyl)-thiazolidine-4-one) (13) (2 mg) was dissolved in 5 mL of glacial acetic acid and the solution was mixed with 20 μL Tween 80. Then, 0.25 mL CSLMW gel (0.05% w/v) was added and the mixture was stirred for one hour. Afterwards, 2 mL of TPP solution (0.5% w/v) were added dropwise slowly using syringe dropping method and the suspension was stirred for another 2 h. The conversion of the solution from clear to opaque appearance indicated nanoparticles formation. The particles formed were separated by centrifugation. The supernatant was removed and spectrophotometrically analyzed for loading efficiency evaluation, and xanthine derivative-loaded CSNPs were dispersed in distilled water for further characterization. Particle size and polydispersity measurements were run in triplicate.

Loading efficiency (LE)

The amount of xanthine derivative in the CSNPs was evaluated using UV spectrophotometric method (UVIKNO XL, BIOTECH Instruments). After centrifugation of the xanthine loaded CSNPs suspension, the supernatant was spectrophotometrically analyzed at 280 nm for evaluating the content of xanthine derivative in the TPP solution.

The loading efficiency (%) was calculated using the following formula:

$$LE\ (\%) = C_1/C_0 \times 100$$

where: C_0 = initial concentration of the xanthine derivative (mg/ml); C_1 = concen-

tration of the xanthine derivative in the TPP solution (mg/ml) (14).

RESULTS AND DISSCUSION

Chitosan nanoparticles formulations

Chitosan (CS) undergoes nucleophilic interaction with the cross-linking agent (TPP) resulting in CSNPs formation. Chitosan with a pKa of 6.3 is polycationic and presents NH_3^+ sites when dissolved in acidic medium (acetic acid). When sodium tripolyphosphate ($Na_5P_3O_{10}$) is dissolved in water it dissociates to give both hydroxyl and phosphoric ions. In the present study, the pH of TPP was selected to be 9.0 and at this pH both hydroxyl and phosphoric ions are and may compete with each other to interact with the NH_3^+ of chitosan (13). The hydroxyl ions get linked to the amino groups by deprotonation. The chemical structure of chitosan (a), tripolyphosphate (b) and xanthine derivative (c) are presented in figure 1.

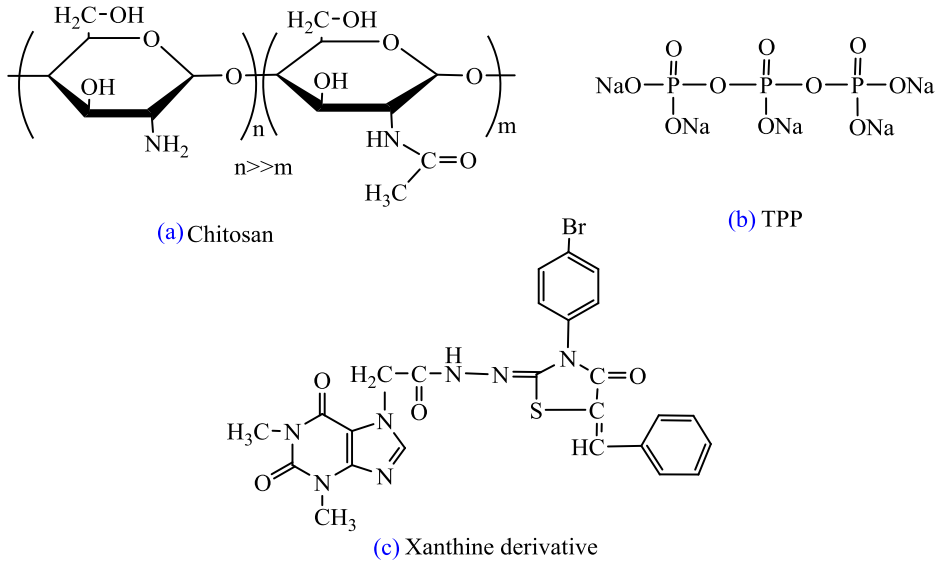

Fig.1 The chemical structure of chitosan (a), tripolyphosphate (b), xanthine derivative (c)

The size of the particles according to different concentration of CSLMW, TPP and stirring speed during ionic gelation are shown in tab. I. By varying these parameters NPs in the range of 231-963 nm were obtained.

The increase in CS concentration was associated with an increase in particle size due to the large number of amino groups that are able to interact as reported in the literature. As can be seen in table I, the average diameter of NPs was about 200 nm when CS concentration was 0.05% w/v while the size increased more than four times when the concentration of CS was 0.25% w/v. At the same time it was noticed that at the higher concentration of TPP the particle size decreased with increasing cross-linking degree of the CSNPs which adopt a more compact and stable structure. The stirring speed during NPs formation also influences their size; thus by increasing the speed from 700 rpm to 1000 rpm there was a decrease in the NP size. NPs have a high surface area and this may lead to very high aggregation after long periods

of storage. After 72 h of storage, the aggregation tendency was more pronounced, the NPs size being higher comparative with the initial size. The PDI changed from 0.179 to 0.517 for NPs stored less than 48 h, indicating good dispersity for all CSNPs.

TABLE I

The size of CSNPs obtained by ionic cross-linking method

Conc. of CSLMW solution (%)	Conc. of TPP solution (%)	Stirring speed (rpm)	Particle average size initial (nm)	Particle average size after 48 h (nm)	Particle average size after 72 h (nm)
0.05	0.1	700	394 ± 19	431 ± 21	651 ± 23

CSNPs-xanthine derivative and loading efficiency

Because particle size is the most important characteristic of NPs systems in terms of drug release, for drug loaded CSNPs the following formulation was chosen: CSLMW 0.05%, TPP 0.5% under 1000 rpm stirring speed during ionic gelation. The size of CSNPs loaded with xanthine derivative obtained without Tween 80 is slightly increased (267 nm), but the size decreases in the presence of Tween 80 as shown in Table II. Also seen was a similar LE% after variation in surfactant concentration which means that the entrapment efficiency was not affected.

TABLE II

The size of CSNPs-xanthine derivative and the loading efficiency

Xanthine derivative (mg)	Tween 80 (µL)	Initial average particle size (nm)	Average particle size after 72 h (nm)	PDI	LE (%)
5	-	267 ± 18	468 ± 11	0.26 ± 0.7	86.10 ± 2.8
5	10	214 ± 12	221 ± 20	0.17 ± 1.4	86.50 ± 3.1
5	20	193 ± 23	195 ± 17	0.52 ± 0.9	86.20 ± 2.4

CONCLUSIONS

The aim of this study was to develop and optimize a method for preparation of CSNPs in order to be used as delivery system for xanthine derivative. Some parameters such as concentration of CS, TPP, Tween 80 and the stirring speed during ionic gelation are very important in

NP formation process. The method was optimized by modifying these independent variables in order to obtain small size NPs, and the optimized method was used for loading the xanthine derivative. The optimized formulation led to xanthine loaded CSNPs with the size in the range 193-214 nm depending on surfactant concentration, without agglomeration effects and with an adequate percentage of loading efficiency.

EXPERIMENTAL RESEARCHES ON ACUTE TOXICITY OF A *BIDENS TRIPARTITA* EXTRACT IN MICE - PRELIMINARY INVESTIGATIONS (Abstract): Plants take up an important place in traditional medicine and scientific research confirmed properties about their use as alternative therapy. *Bidens tripartita*, commonly known as Three-lobe Beggarticks, Three-part Beggarticks, Trifid Bur-marigold, is a flowering plant in the genus Bidens, family Compositae, subfamily Asteroideae. Evaluation of the chemical composition of this plant has revealed the presence of flavonoids, xanthophylls, volatile oil, acetylene and polyacetylene, sterols, aurones, chalcones, caffeine and tannins. Aim: Theoretical data investigation regarding *Bidens tripartita* plant and experimental researches on acute toxicity of an original extract in mice. **Material and methods:** The vegetal product of *Bidens tripartita* used for study was obtained by maceration and extraction in alcohol, and its chemical composition was determined. Acute toxicity of the alcoholic extract of *Bidens tripartita* was assessed by median lethal dose (LD50) calculation, using a limit dose test of up- and- down procedure at a limit dose of 2000mg/kbw after intraperitoneal administration in mice. **Results**: In the alcoholic extract of *Bidens tripartita* different active principles were identified: tannins, anthracene derivatives, triterpenes, coumarins, antocyanosides. The toxicity of plant product was evaluated by different characteristic signs for the mouse which can be retained as toxicity elements of the extract. Using the intraperitoneal route, the animals showed dose-dependent signs of toxicity, ranging from lack of appetite, depression, immobility and respiratory distress to death. Single-dose intraperitoneal LD50 value of the alcoholic *Bidens tripartita* extract in mice was 4038 mg/kg. No macroscopic changes were seen in the organs of mice that died following extract administration. Histopathological lesions were not found in all examined organs. **Conclusions**: The obtained LD50 value classifies the study plant extract as slightly toxic according to Hodge and Sterner toxicity scale. We determined the low toxic dose at a rate of 4038 mg of body weight for the alcoholic extract of this medicinal plant. These results suggest that the alcoholic extract of *Bidens tripartita* is relatively safe toxicologically when administered intraperitoneally, and this product could be used with some degree of safety to continue the investigation for *in vivo* biocompatibility evaluation. **Keywords**: *BIDENS TRIPARTITA*, LETHAL DOSE 50, MICE.

Adaptogens are naturally occurring substances found in rare plants and herbs, which appear to increase body ability to adapt to stress and changing situations (1).

The exact mechanism through which an adaptogen works is unclear so far, as it seems to be caused by the effects of different chemical compounds. In general, adaptogens are all potent antioxidants and they are reported to improve endurance and produce effects associated with stress reduction, for instance, improved sleep and enhanced physical performances (2).

The main effects of adaptogens are represented by: an increased availability of energy during the day, a reduction of stress feelings, increased endurance, greater mental alertness, and deep and restful sleep (3). Also, adaptogens significantly accelerate the recovery process after illness. They can have individual effects, depending on general health, constitution, specific nutrient deficiencies, and medical conditions present in an individual (4).

Bidens tripartita (B. tripartita), commonly known as Three-lobe Beggarticks, Three-part Beggarticks, Trifid Bur-marigold, is a flowering plant in the genus *Bidens*, family *Compositae*, subfamily *Asteroideae*. It is found along streams and ditches, and flowers during late summer and autumn.

Literature data reported that *B. tripartita* contains a significant amount of flavonoids, xanthophylls, volatile oil, acetylene and polyacetylene, sterols, aurones, chalcones, caffeine and tannins (5).

In traditional medicine, infusions of *B. tripartita* are widely used in the treatment of catarrhal rhinitis, angina, acute respiratory infection, and as an anti-inflammatory in colitis and gout (6). It also proved antiseptic, anti-inflammatory, antioxidant, astringent, diuretic, febrifuge, narcotic, sedative and sudorific effects (1,7).

MATERIAL AND METHODS

The study consisted in obtaining an alcoholic extract of *Bidens tripartita* plant, establishing its composition and determining the lethal dose 50% (LD50) after acute intraperitoneal administration in mice.

Collection and processing of plant material. The plant material for the study was represented by an alcoholic extract of *Bidens tripartita L.* plant. Plants were collected during flowering stage in July and August 2009, 2010, 2011 from the Ciric area, Iasi district, where it grows naturally. This medicinal plant species was taxonomically identified and authenticated by botanical specialists.

The vegetal product of *Bidens tripartita* used for the study was obtained by maceration and extraction in alcohol, and its chemical composition was determined.

The plants were washed in water and dried in laboratory using continuous ventilation away from sun light and dust. Then, they were cut into smaller pieces and ground into a coarse powder with a blender. This procedure ensures proper penetration of the extracting solvent into the cell to facilitate the release of the flower's active ingredients. The vegetable product was kept in closed plastic bag. The powder was dissolved in absolute chloroform (96%) and re-extracted seven (times (repeated maceration). The suspension was filtered by filter paper and dried using a Rota vapour. Then, a jet air was used to remove the solvent smell. After complete dryness, the product was extracted by the addition of ethanol seven times (repeated maceration) following the same procedure of evaporation. Finally, the extract was weighed by digital balance, stored in bottles and kept in the laboratory refrigerator for further research (8).

Animals. Swiss white male mice (30-40 g) were used. The animals were housed under standard laboratory conditions (rela-

tive humidity 55-65%, room temperature 23.0±2.0°C and 12 hours light: dark cycle (lights on at 6:00 a.m.)). The animals were fed with standard diet and water *ad libitum*, except during the time of experiments. Before the experiment, mice were placed on a raised wire mesh, under a clear plastic box and allowed 2 hours to acclimate to the testing room.

Acute toxicity investigation. This study was designed to evaluate the *Bidens tripartita* extract acute toxicity *in vivo*, after intraperitoneal administration in mice.

Median lethal dose (LD50) is the dose, given all at once, which causes the death of half the number of test animals. LD50 is one way to measure the short-term toxic potential of a product (9). Establishing of LD50 in lab animals is very important to estimate the degree of acute toxicity of a tested substance (12).

The acute toxicity of the alcoholic *Bidens tripartita* extract was assessed by LD50 calculation, using a limit dose test (up-and- down procedure) at a limit dose of 2000 mg/kg bw of each vegetal extract after intraperitoneal administration in mice (five animals per group) (OECD-OCDE 425 Guide).

LD_{50} determination of *Bidens tripartita* extracts was estimated where all doses were expressed in terms of extract weight/ animal weight. Preliminary experiments were done to determine the minimal dose that kills all animals (LD100) and the maximal dose that fails to kill any animal. Several doses at equal logarithmic intervals were chosen in between these two doses, each dose being injected intraperitoneally in a group of five animals. The mice were observed for 14 days and symptoms of toxicity and mortality rates in each group were recorded and LD50 was calculated.

The toxicity of plant product was evaluated by different characteristic signs for the mouse which can be retained as toxicity elements of the extract. Using the intraperitoneal route, the animals showed dose-dependent signs of toxicity, ranging from lack of appetite, depression, immobility and respiratory distress to death (11).

The arithmetic method of Karber with the following formula was used:

$$LDL50 = LD100 - \sum(axb) / n$$

a = the difference between two successive doses of administered substance

b = the average number of dead animals in two successive groups

n = the number of animals in a group,

DL100 = lethal dose 100% (representing the dose, given all at once, which causes the death all test animals).

Graphic curve was realized with experimental data to have LD01, LD50, LD99. Much more, two ratios: LD99/LD50 and LD50/LD01 were calculated and compared.

The determined LD50 value allowed us to find out the level of toxicity of the plant product on the toxicity scale suggested by WHO/IPCS (2002) representing an adaptation of the Hodge and Sterner scale (1980) (1).

Data were statistically analyzed with SPSS software for Windows version 17.0 and ANOVA one-way method. The results were expressed as mean of LD01, LD50 and LD99 ± S.E.M. (standard error of mean).

Experimental protocols were implemented according to recommendations of the "Grigore T. Popa" University Committee for Research and Ethical Issues. Each animal was used only once, and the duration of the experiments was kept as short as possible. For ethical reasons, all the animals were sacrificed at the end of the ex-

periment (13).

RESULTS AND DISCUSSION

Phytochemical analysis of the vegetal extract of *Bidens tripartite*, consisting of simple chemical tests, detected the presence of different active principles, especially tannins, anthracene derivatives and triterpenes (tab. I).

TABLE I

Active principles identified in the extract of *Bidens tripartita* plant

Extract	Active substances
Ethanolic	tannins, anthracene derivatives, triterpenes, coumarins, antocyanosides

The toxicity of *Bidens tripartita* extract was evaluated according to different signs for the mouse, which can be retained as toxicity elements of the vegetal product: decrease in spontaneous behavior normal manifestations and exploration instinct, somnolence, lack of appetite, depression, respiratory distress, and death.

The LD50 value of *Bidens tripartita* extract administered intraperitoneally in a single dose was estimated to be 4038 mg/kbw in mice (fig.1)

DL01 and DL99 of the alcoholic *Bidens tripartita* extract injected intraperitoneally in mice were determined to be 2500 mg/kbw and 4950 mg/kbw, respectively.

The calculation of DL99/DL50 ratio = 1.22 and DL50/DL01 ratio = 1.61 showed comparable values expressing the steadiness of regression line for mortality in relation to dose and validate the biologic significance of the results.

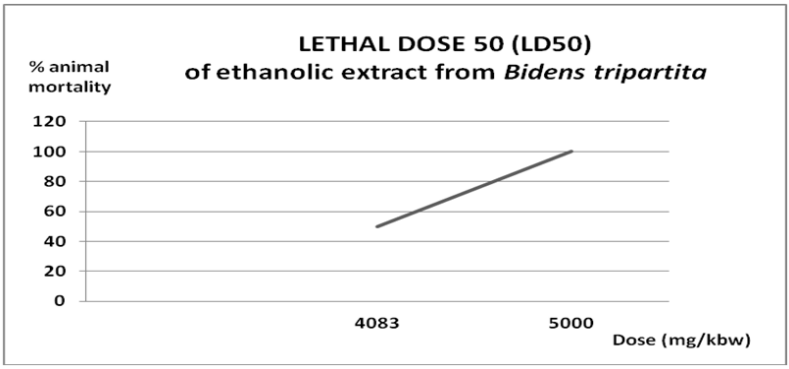

Fig. 1. Curve of the general acute toxicity of alcoholic extract from *Bidens tripartita*

TABLE II

Hodge and Sterner Toxicity Scale (1980)(1)

Toxicity rating	Commonly used term	LD50 (rat, oral)
1	Extremely Toxic	less than 1 mg/kg
2	Highly Toxic	1-50 mg/kg
3	Moderately Toxic	50-500 mg/kg
4	Slightly Toxic	500-5000 mg/kg
5	Practically Non-toxic	5000-15000 mg/kg

According to Hodge and Sterner toxicity scale, the LD50 value of the alcoholic *Bidens tripartita* extract is in the slightly toxic category (tab. II). For the future researches the retained dose of the alcoholic extract from *Bidens tripartita* for mouse administration is 1/20 LD50, that is around 201.9 mg/kg bw.

CONCLUSIONS

These results suggest that the alcoholic extract of *Bidens tripartita* is relatively safe toxicologically when administered intra-peritoneally, and this product could be used with some degree of safety to extend the researches for *in vivo* biocompatibility evaluation.

This study is a preliminary investigation on acute toxicity of an alcoholic extract from *Bidens tripartita* offering an outset to continue the researches regarding the effects of this vegetal product on biochemical parameters, immune system, and oxidative stress in lab animals.

STAREA DE SUPRAFAȚĂ A RESTAURĂRILOR FIXE ŞI INFLUENȚA ASUPRA PARODONȚIULUI

Alice-Arina Ciocan-Pendefunda[1], **Norina Consuela Forna**[2]
1. Doctorand al Universității de Medicină şi Farmacie „Grigore T. Popa" - Iaşi
Universitatea de Medicină şi Farmacie „Grigore T. Popa" - Iaşi
2. Facultatea de Medicină Dentară

SURFACE ASPECT OF FIXED RESTAURATIONS END PARODONTAL INFLUENCES (Abstract): Any new class of materials requires a new cutting technology which, unless complied with properly, may negatively impact on the advantages and performance of the material. The modifications appeared as a result of the technological processes in the structure or surface aspect of the materials not only affects the mechanical resistance of the restorations but also casts doubts on their biological qualities. **Aim**: This study evaluates the impact of biomaterials involved in fixed restorations on the periodontal architecture, bearing extremely important connotations in the long run. **Material and methods**: The "in vitro" testing was conducted on culture cells for the cytotoxic effect of certain restorative materials – metallic alloys used in prosthetic restorations, composite materials, in collaboration with the Virology Laboratory of the Public Health Institute.The tested materials were metallic alloys, composite materials and acrylic resins used for the construction of standard sized plates (out of each material) in order to avoid the differences that might arise from the technological process. Artificial saliva processed to reach a pH=7 was prepared in the Biophysics Laboratory of UMF Iasi. Material samples and the saliva inoculated with these were tested. –p. **Results and discussions:** The cytotoxic effect of the tested materials on the celular cultures takes on extremely diverse forms, from discrete morphological modifications of the cells with regard to the size, shape, internal structure (for the noble and semi-noble alloys) up to the partial stripping-off of the celular film, the modification of density and coloration. In the case of the witness of non-inoculated culture, *the testing results* showed the presence of a continuous film, with cells having the same size, transparency and colouring, with an unaltered polyhedral contour, with visible nuclei, an image also kept in the case of the saliva witness. **Conclusions.** The involvement of restaurative materials in triggering, maintaining and aggravating a periodontal pathology indicates the capital role played by the dentist in the identications of lesions during measures by avoiding or excluding etiological agents before an obvious lesions occurs in the process of active dispensarization**. Key words**: BIOCOMPATIBILITY, DENTAL BIOMATERIALS, PERYODONTIUM, FIXED RESTAURATIONS

Numărul mare şi diversificarea în ritm accelerat a materialelor restaurative cu o compoziție chimică din ce în ce mai sofisticată, creşte riscul apariției unor fenomene toxico-iritative, alergice şi de altă natură, ceea ce a suscitat din partea specialiştilor un interes crescut privind comportarea lor în diverse condiții de exploatare.

Proprietățile mutagene ale unor materiale stomatologice reprezintă un pericol pentru sănătatea omului şi introducerea unei strategii logice a testării devine o necesitate, deşi metodologia de investigare este încă limitată (5).

Testele de toxicitate, au avantajul că se verifică materialele ca atare dar şi componentele acestora, ceea ce permite eliminarea substanțelor accentuat toxice într-o fază timpurie (4).

Orice clasă nouă de materiale necesită o tehnologie nouă de prelucrare care, dacă nu este respectată, poate compromite avantajele şi performanțele materialului.

Modificările rezultate în urma proceselor tehnologice în structura sau aspectul de suprafață a materialelor nu numai că influențează în mod negativ rezistența mecanică a restaurațiilor dar pune la îndoială şi calitățile biologice ale acestora. Aşa se explică apariția unor reacții parodontale sau mucozale de vecinătate. Experiența clinică atrage atenția asupra unor astfel de reacții adverse posibile la materialele restaurative (aliaje metalice şi materiale acrilice, materiale compozite (2).

În ultimele decenii a devenit posibilă testarea biocompatibilității diferitelor materiale stomatologice pe animale de experiență sau *in vitro* pe culturi celulare, metoda fiind utilizată atât pentru materiale ca atare cât şi pentru elementele ce le compun. Aplicând cele mai simple tehnici se poate permite contactul materialului cu celula vie, rezultatele fiind în funcție de toxicitatea materialului.

Scopul acestui studiu urmăreşte evaluarea impactului biomaterialelor folosite in restaurarile fixe asupra arhitecturii parodontale, cu implicatii importante pe termen lung.

MATERIAL ŞI METODE

S-a efectuat testarea „in vitro" pe culturi de celule a efectului citotoxic al unor materiale restaurative-aliaje metalice utilizate în restaurările protetice, materiale compozite, în colaborare cu Laboratorul de Virusologie al Institutului de Sănătate Publică Iaşi. Au fost testate aliaje metalice, materiale composite şi răşini acrilice din care s-au realizat plăcuțe de dimensiuni standard pentru a evita diferențele ce ar putea decurge din procesul tehnologic.

Ca suport celular pentru testarea acestor biomateriale s-a folosit: linia de celule epiteliale tip HeLa - pentru materialele compozite şi acrilice; fibroblaşti din ser de viței proaspăt - pentru aliajele metalice. Mediile utilizate pentru creşterea şi întreținerea culturilor au fost livrate de Institutul Cantacuzino, Bucureşti. Saliva artificială adusă la un pH =7 a fost preparată în Laboratorul de Biofizică UMF Iaşi, sterilizată prin autoclavare 20 de minute şi controlată din punct de vedere bacteriologic.

Fragmentele de material au fost introduse în recipiente sterile cu salivă şi păstrate la temperatura camerei, de unde, la intervale de 3, 6 şi 18 zile au fost recoltate probe (0, 2 ml) în vederea testării efectului citotoxic. Câte 5 eşantioane din probele de salivă, au fost inoculate în tuburi de culturi celulare, ulterior mediul de creştere a fost înlocuit cu cel de întreținere.

Ca martor şi element de comparație s-au folosit tuburile inoculate cu salivă artificială şi cele neinoculate.

Efectul citotoxic s-a urmărit macroscopic şi microscopic proliferarea sau liza celulară survenită, refringența, continuitatea filmului celular sau tulburarea lanțului adeziune - multiplicare şi aderare de pereții vasului. Lipsa aderării, cu formarea filmului celular pe pereții vasului a reprezentat

semnul morții celulare, iar tehnicile histologice au permis evaluarea microscopică.

REZULTATE ŞI DISCUȚII

Efectul citotoxic al materialelor testate asupra culturilor celulare îmbracă aspecte din cele mai variate, de la modificări morfologice discrete ale celulelor privind mărimea, forma, structura internă (pentru aliaje nobile şi seminobile) până la desprinderea parțială a filmului celular, modificarea densității şi a colorației (4).

TABELUL I

Testarea citotoxicității materialelor inoculate în salivă pe culturi de celule

Materiale	3 zile	6 zile	18 zile
Salivă artificială inoculată cu compozit autopolimerizabil	+ 1/5	+2/5	0/5
Salivă artificială inoculată cu compozit fotopolimerizabil	0/5	+1/5	0/5
Salivă artificială inoculată cu acrilat termopolimerizabil	0/5	+1/5	0/5
Salivă artificială inoculată cu acrilat autopolimerizabil	**+2/5**	**+++4/5**	**++3/5**
Salivă artificială inoculată cu aliaj nobil	0/5	0/5	0/5
Salivă artificială inoculată cu aliaj seminobil Pd - Ag	0/5	+1/5	0/5
Salivă artificială inoculată cu aliaj oțel inoxidabil Cr-Co	0/5	0/5	0/5
Salivă artificială inoculată cu aliaj Cr-Ni	+1/5	+1/5	0/5
Cr-Co Soft	0/5	0/5	0/5
Salivă neinoculată	0/5	0/5	0/5
Martor cultură	0/5	0/5	0/5

În cazul martorului cultură neinoculată, rezultatele testărilor au arătat prezența unui film continuu, cu celule de aceeaşi mărime, transparență şi colorabilitate, cu contur poliedric nealterat, cu nuclei vizibili, imagine ce se păstrează şi la martorul salivă (tab. I, fig. 1).

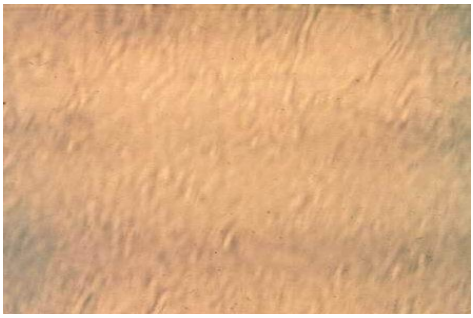

Fig. 1. Martor celular normal

Nici una din cele 5 probe nu a arătat modificări esențiale la 3 săptămâni, filmul celular fiind confluent, cu celule cu contur poligonal ce prezentau o uşoară modificare de volum dar fără picnoză, cu nuclei clari, ovalari, cu structura fină a cromatinei. Creşterea în culturile martor a început imediat în zilele următoare inoculării şi a progresat treptat.

Analiza tuburilor cu salivă inoculată cu material acrilic termopolimerizabil şi compozite fotopolimerizate a indicat lipsa toxicității în primele zile ale testării, un efect redus de toxicitate remarcându-se la unul din tuburi la 6 zile de testare, efect ce a dispărut la 18 zile (tab. I, fig. 2).

Reacția citolitică remarcată la compozitele autopolimerizabile poate fi atribuită monomerului eliberat (1 tub la 3 zile şi 2 la 6 zile), iar la cele fotopolimerizabile (1 tub) la evaluarea la 6 zile, reacția poate fi pusă pe seama polimerizării incomplete (tab. I, fig. 3).

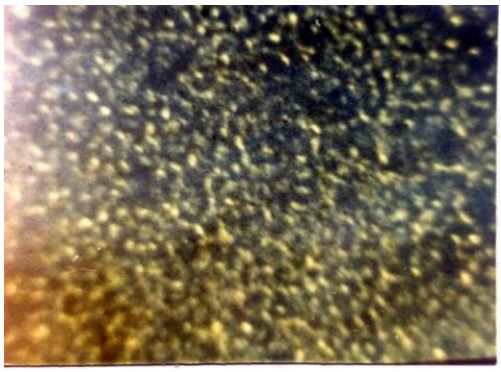

Fig. 2. Film celular continuu x10

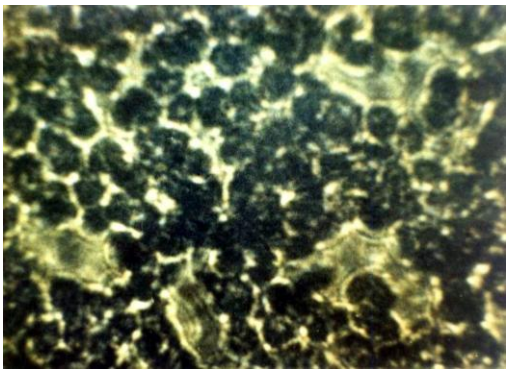

Fig. 3. Reacție citolitică citolitică uşoară X20 - compozit

Reacție citolitică intensă la acrilatele şi compozitele autopolimerizabile, cu distrucția şi chiar desprinderea filmului celular, mai redus în primele 3 zile (2 respectiv 1 tub) şi mai intens la 6 zile (4 respectiv 2 tuburi) şi la 3 săptămâni, când doar acrilatul autopolimerizabil continuă să abă efecte citotoxice (3 tuburi) (tab. I, fig. 4).

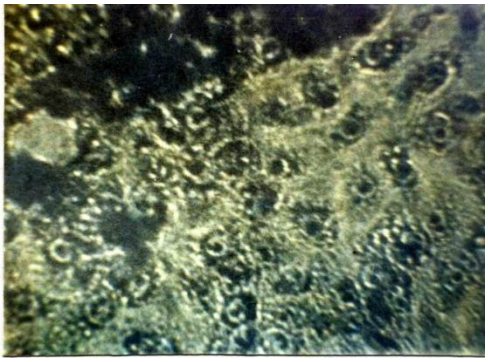

Fig. 4. Reacție citolitică intensă 20 X acrilat autopolimerizabil

Toxicitatea aliajelor evaluată după răspunsul citotoxic în mediu de cultură şi viabilitatea celulară apreciată prin continuitatea filmului celular, ne indică o viabilitate mai crescută la aliajele nobile, unde filmul celular apare continuu, neîntrerupt, cu celule fără refringență sau rare celule refringente la aliajele seminobile, dar cu o reducere a refringenței celulare şi afectarea proliferării acestora, în prezența ionilor de cupru (tab.I, fig.5).

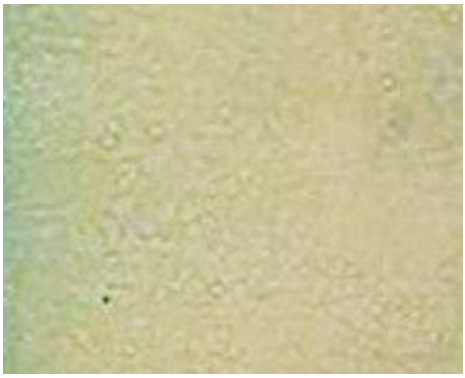

Fig. 5. Aliaj aur, film celular continuu, neîntrerupt, cu celule fără refringență

La Pallidor filmul apare cu rare celule refringente (fig. 6), în timp ce la Palliag imaginile arată goluri cu celule ce se desprind, fără refringență şi balonizate (fig. 7).

La aliajele de Cr-Co (hard) (fig. 8) şi Cr-Co-Mo (fig.9) suspensia şi filmul celular evidențiază un aspect şi un contur celular nemodificat.

La Cr-Co soft şi Cr-Co suspensie, se observă celule ce se desprind, dar cu tendință de refacere (fig. 10, 11).

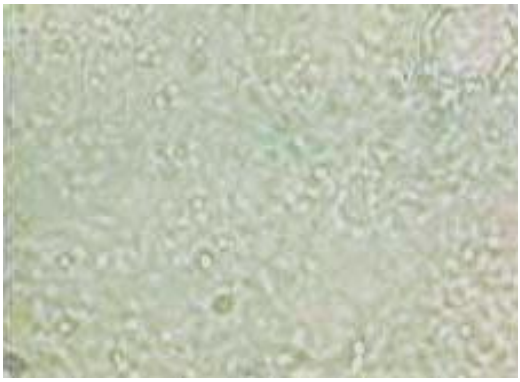

Fig. 6. Palidor - film continuu, cu rare celule refringente.

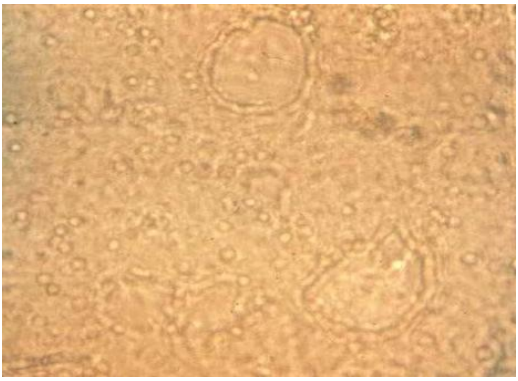

Fig. 7. Palliag - film cu celule ce se desprind

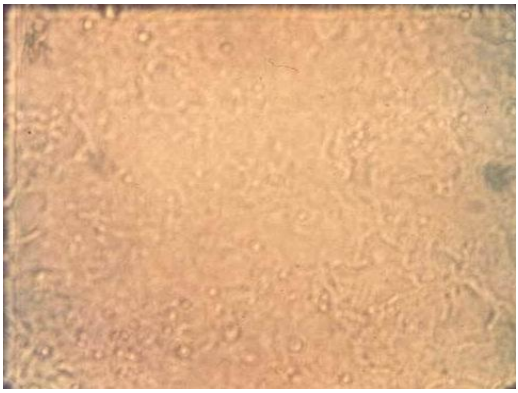

Fig. 8. Cr-Co Hard- Suspensie aspect și contur celular nemodificat

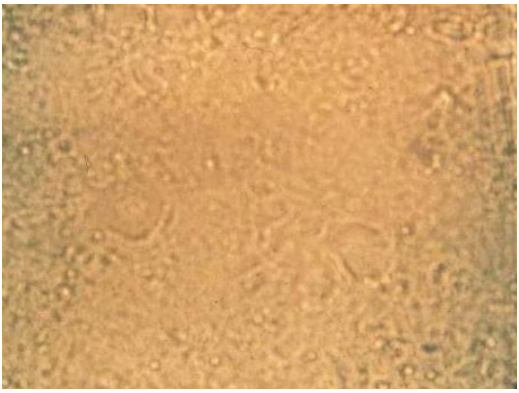

Fig. 9. Suspensie Cr-Co-Mo - film neîntrerupt cu celule normale

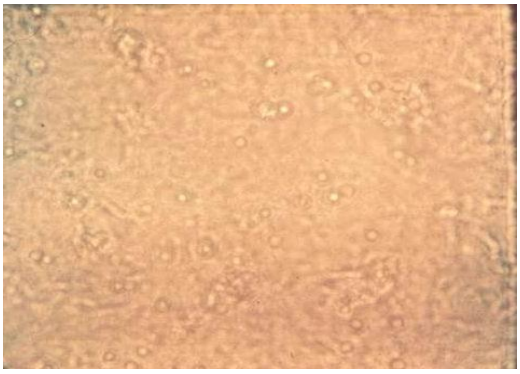

Fig. 10. Cr-Co soft + Ni - film întrerupt cu celule refringente, ce se desprind dar se refac

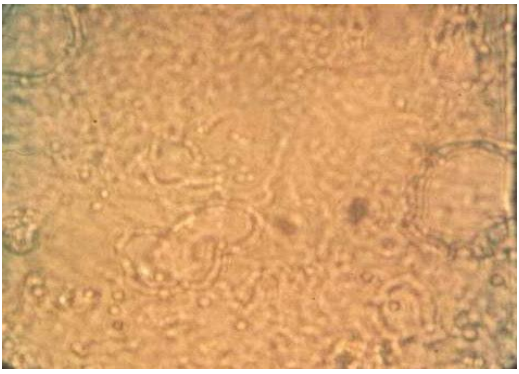

Fig. 11. Cr-Co Suspensie – celule ce se desprind dar se refac

Rezultate asemănătoare au fost obținute prin introducerea concomitentă în tuburi, odată cu însămânțarea suspensiei de cultură celulară a fragmentelor din materiale (5).

Urmărind gradul de creştere a filmului celular şi modificările morfologice apărute, viabilitatea celulelor în prezența materialului comparativ cu martorul, se constată modificări asemănătoare celor din experimentul cu saliva inoculată.

Aliajele, în principal acelea pe bază de cupru pot elimina în salivă ioni şi alți produşi de coroziune, în concentrații care uneori pot afecta viabilitatea şi proliferarea celulară (6, 7). Efectul toxic asupra culturilor celulare demonstrează trecerea ionilor metalelor de bază în saliva artificială şi acțiunea lor toxică asupra culturilor de celule.

În tuburile cu fragmente din acrilat termopolimerizabil şi compozite fotopolimerizabile aliaje nobile, seminobile şi Cr-Co în primele 48 de ore de incubare la 37°C s-a produs creşterea filmului celular, care examinat la microscop înainte şi după colorare arată formarea unui monostrat confluent de cultură celulară, exceptând zona în care este depus fragmentul, unde pare să apară un lizereu de celule mai aglomerate şi turtite, iar modificări discrete să se remarce la 6 zile, demonstrând gradul redus de toxicitate.

Modificări evidente de citotoxicitate s-au remarcat la fragmentele de acrilat autopolimerizabil şi aliajelor pe bază de Cu, dar chiar din primele zile de incubare, când distrucția filmului celular s-a produs nu numai la nivelul contactului, ci şi la distanță, ce ar indica fie toxicitatea materialului prin el însuşi, fie prin componentele sale eliberate în mediul de cultură, cum este cazul monomerului, cuprului, nichelului

Modificările discrete constatate la fragmentele de compozit fotopolimerizabil, aliaje nobile, seminobile, Cr-Co pot fi puse pe seama traumatismului fizic la contactul celule - material şi diferențiate de efectul citotoxic. Rezultatele testărilor sunt în concordanță cu datele din literatură.

Testarea citocompatibilității aliajelor Fe-Cr-Ni şi Cr-Co în studii recente indică absența efectului citotoxic la perioade scurte de timp dar remarcă efecte citotoxice la aliajul Cu-Al-Ni (8, 9).

Craig et al.(8), testând efectele aliajelor dentare pe bază de Cu asupra liniilor celulare gingivale au constatat că prezența ionilor de Cu şi Ni poate determina o reducere a proliferării şi a vitalității celulare cu o scădere a tolerabilității biologice şi un risc de citotoxicitate ridicat în mediul bucal, ceea ce atrage atenția asupra indicării cu discernământ a acestor materiale sau chiar a evitării utilizării lor.

Efectuarea testului de citotoxicitate este pretențioasă şi foarte riguroasă, începând cu elaborarea probelor şi terminând cu interpretarea rezultatelor obținute pe culturi de celule din care un procent cu atât mai mare îşi pierde vitalitatea cu cât biomaterialul este mai toxic.

CONCLUZII

Studiul nostru a arătat modificări evidente de citotoxicitate la acrilatul autopolimerizabil şi la aliajele pe bază de Cu, chiar din primele zile de incubare, când distrucția filmului celular s-a produs nu numai la nivelul contactului, ci şi la distanță, ceea ce ar indica fie toxicitatea materialului prin el însuşi, fie prin componentele sale eliberate în mediul de cultură, cum este cazul monomerului, cuprului, nichel

Compozitul fotopolimerizabil, aliajele nobile şi seminobile au determinat modificări discrete ce pot fi puse pe seama trau-

matismului fizic la contactul celule - material şi diferențiate de efectul citotoxic.

Efectul ionilor de Cu şi Ni din aliajelor dentare pe bază de Cu asupra liniilor celulare gingivale, poate determina o reducere a proliferării şi vitalității celulare cu o scădere a tolerabilității biologice şi un risc de citotoxicitate ridicat în mediul bucal.

NOUTĂȚI

CHLAMYDIA TRACHOMATIS - NOI MODALITĂȚI DE INVESTIGARE

Infecțiile cu *Chlamydia trachomatis* sunt dintre cele mai frecvente infecții de la nivelul tractului genital deşi mecanismul prin care aceasta se adaptează țintei (celulele epiteliale endocervicale) nu este clar înțeles. Pentru a-şi asigura supraviețuirea intracelulară aceasta secretă factori de virulență insuficient investigați. Studiul de față foloseşte linii celulare HeLa şi linii celulare de celule epiteliale endocervicale pentru a pune în evidență proteinele bacteriene secretate în timpul creşterii induse de ampicilină. În mod specific se observă o scădere a CPAF (chlamydial protease like activity factor) în citosolul celulelor expuse ampicilinei în condițiile în care CPAF produs de *Chlamydia trachomatis* este constant. Pe de altă parte, expresia CopN şi Tarp este scăzută sugerând că *Chlamydia trachomatis* răspunde la expunerea la ampicilină prin alterarea selectivă a expresiei genelor care codifică secretia proteinelor. De asemenea, se observă o acumulare de vezicule în celulele cu infecție persistentă. Aceste rezultate susțin ipoteza că atât expresia genelor cât şi secreția factorilor de virulență sunt implicați în adaptarea bacteriei la micromediul tractului genital în cazul infecțiilor persistente (Wang J, Frohlich K, Buckner L et all. Altered protein secretion of *Chlamydia trachomatis* in persistently infected human endocervical epithelial cells. *Microbiol* 2011: l 157, 2759-2771).

2. Disciplina de Microbiologie

SYNTHESIS AND CHARACTERIZATION OF SOME NEW RUTIN AND 7-AMINO-CEPHALOSPORANIC ACID DERIVATIVES (Abstract): Many studies show that flavonoids have a numerous biological properties, antimicrobial effects included. It is also known that rutin is able to increase the antibacterial activity of other compounds. **Material and methods:** Starting from these facts, we synthesised some water soluble rutin derivatives treating rutin with 1, 3-dichloro-2-propanol, 1-bromo-3-chloro-propane, 2-dibromethane, and dibrommethane, and than with 7-amino-cephalosporanic acid. The antimicrobial activity of the new compounds was determined by disc diffusion method. **Results:** Molecular formula, weight, yield, melting points and solubility of the new derivatives have been determined. Elemental analysis and spectral analysis (UV and IR) confirmed the structure of new compounds. **Conclusions.** These derivatives are water-soluble and have a good antimicrobial activity, both on Gram-positive and Gram-negative bacteria, comparable with that of tetracycline. **Key words:** FLAVONOIDS, RUTIN, CEPHALOSPORIN, ANTIMICROBIAL ACTIVITY

Multitudinea de studii întreprinse până în prezent a stabilit faptul că flavonoidele prezintă numeroase proprietăți biologice (antioxidantă, antiinflamatoare, antialergică, antimicrobiană, antivirală, antitumorală, etc.) exercitate prin variate mecanisme de acțiune. În multe cazuri, flavonoidele sunt capabile de protecție împotriva unor afecțiuni cronice şi degenerative, dintre care amintim cancerul, bolile cardiovasculare, disfuncții ale sistemului imunitar, etc. Mai mult decât atât, există dovezi că rutozidul ar potența acțiunea antimicrobiană a unor compuşi cunoscuți a avea astfel de proprietăți (1-9).

MATERIAL ŞI METODĂ

Pornind de la aceste premize, ne-am propus obținerea unor derivați ai rutozidului cu acidul 7-amino-cefalosporanic, prin tratarea rutozidului cu 1,3-dicloro-2-propanol, 1-brom-3-cloro-propan, 2-dibrom-etan şi dibrom-metan, în mediu de metoxid de sodiu, şi apoi cu acidul 7-amino-cefalosporanic (fig. 1). Derivații I-IV au fost obținuți după aceeaşi tehnică de lucru: 0,01 mol (6,64 g) rutozid (V) se introduc într-un flacon Erlenmayer cu dop rodat, peste care se adaugă 180 ml metoxid de sodiu (preparat prin reacționarea a 0,01 mol (0,23 g) cu metanol absolut). Amestecul de reacție se supune agitării magnetice la temperatura camerei,

timp de 60 de minute. Se adaugă derivaţii halogenaţi (0,01 mol 1,3-dicloro-2-propanol (VI), 1-brom-3-cloro-propan (VII), 2-dibrom-etan (VIII), respectiv, dibrom-metan (IX)) şi se continuă agitarea magnetică timp de 2 ore. Înainte de adăugarea acidului 7-amino-cefalosporanic s-a verificat pH-ul amestecului de reacţie, situat în jurul valorii 7-8. În final, se adaugă 0,01 mol acid 7-amino-cefalosporanic (X) şi amestecul de reacţie se agită timp de 12 ore. Soluţia obţinută se lasă în repaus 24 ore şi apoi se toarnă în porţiuni mici, sub agitare peste 400 ml izopropanol. Precipitatul format se filtrează şi se usucă în etuva termostatată, la 37°C, timp de 12 ore. Produsul brut se purifică pe coloană (Ø 0,5 cm, 15 cm lungime) cu Silicagel H (dimensiunea particulelor 10-40 μm), debitul soluţiei în alcool 50° fiind de 0,25-0,30 ml/min.

III	Br	Br	CH_2	H	-
IV	Br	Br	-	H	-

Fig. 1. Sinteza derivaţilor de rutozid

Analiza elementală C, H, N s-a realizat cu un aparat “Exeter Analytical” CE-440; spectrele IR ale derivaţilor obţinuti au fost efectuate prin metoda comprimării în pastile de KBr (în raport 1/30), înregistrarea fiind realizată cu ajutorul unui aparat FT/IR "Jasco 670 Plus", în domeniul 500-4000 cm^{-1}; spectrele UV au fost înregistrate utilizând un spectrofotometru UV-VIS “Hewlett-Packard” HP 8453 E şi softul de firmă “HP-CHEMSTATION”. S-au folosit soluţii apoase de concentraţie 10 μg/ml, solventul de compensare fiind apa bidistilată.

Testările microbiologice s-au făcut pe mediu agarizat, tip Mueller-Hinton (Oxoid) şi pe agar Sabouraud, utilizând ca microorganisme test: *Staphylococcus aureus* ATCC 25923, *Staphylococcus aureus* meticilin rezistent (meti- R), *Sarcina lutea* ATCC 9341, *Bacillus cereus* ATCC 14579, *Bacillus subtilis*, *Escherichia coli* ATCC 25922, *Pseudomonas aeruginosa*, o tulpină de *Klebsiella pneumoniae* 1, producătoare de betalactamaze cu spectru extins (BLSE), *Candida albicans* ATCC 10231, *Candida sake* şi *Candida glabrata*. Tulpinile utilizate în teste fac parte din colecţia de microorganisme a Disciplinei de Microbiologie, Facultatea de Farmacie, U. M. F. "Gr. T. Popa", Iaşi.

Activitatea antimicrobiană a compuşilor I-IV s-a studiat prin metoda difuzimetrică. Din cultura peste noapte, incubată la temperatura optimă (30°C), s-a preparat o suspensie cu densitatea corespunzătoare tubului 0,5 din scala turbidimetrică Mc Farland. Suspensia s-a încorporat în proporţie de 1/10 în mediu Mueller-Hinton topit şi răcit la 50°C. Din amestec, după omogenizare, s-au repartizat câte 25 ml în plăci Petri cu diametrul de 12 cm. Pe suprafaţa fiecărei plăci, s-au dispus, după solidificare, rondele de hârtie de filtru impregnate cu derivaţii de testat. Rezultatele au fost citite după menţinerea plăcilor la termostat, la 37 grade Celsius, timp de 24 ore, pentru bacterii şi la 24 grade Celsius, timp de 48 de ore, pentru *Candida spp*. S-a măsurat cu şublerul şi s-a înregistrat diametrul zonelor de inhibiţie. S-a comparat activitatea antimicrobiană a probelor cu activitatea tetraciclinei (30 μg/disc), cotrimoxazolului (25μg/ disc), sulfamidei (200 μg/ disc) şi, în cazul fungilor, cu cea a nistatinei (100 μg/ disc).

REZULTATE ŞI DISCUŢII

Derivaţii I-IV au fost obţinuţi cu randamente satisfăcătoare (82-90%); aceştia se prezintă sub formă de pulberi cristaline galbene, higroscopice, solubile în apă, etanol 50°, dimetilsulfoxid şi dimetilformamidă la rece, etanol 96° şi metanol la încălzire, parţial solubile în propanol, de asemenea la cald şi practic insolubile în izopropanol, dioxan, eter etilic, acetona, benzen şi cloroform; soluţiile apoase au un pH ≅ 7.

Compuşii au fost caracterizaţi prin stabilirea formulelor şi maselor moleculare, a denumirilor chimice conform normelor IUPAC, determinarea punctelor de topire şi calculul randamentelor, iar structura lor a fost confirmată prin analiză elementală C,H,N şi analize spectrale în IR şi UV, după cum urmează:

3-[[6-O-(6-deoxy-α-L-manopiranozil) - β - D - glucopiranozil] - oxi] - 2 -(3, 4 - dihidroxifenil) – 5 – hidroxi - 7-(oxi-1-(β-hidroxi- propil)3-(3 - (acetiloximetil)-7-amino-8-oxo-5-tia-1-azabiciclo[4.2.0]oct-2-enil-2-carboxil)) - 4H-1-benzopiran-4-ona (I)

$C_{40}H_{46}N_2O_{22}S$; Mr = 938.86; Randament: 89,75; p.t.° (punct de topire) = 186-191°C; Analiza elementală (C,H,N) (Calculat / Experimental): 51,17; 4,93; 2,98/51,11; 4,88; 2,91; IR (cm^{-1}): 3423 (NH), 3333 (OH legate), 2923 (CH), 1733 (-C=O beta-lactamic), 1669 (C=O pe nucleu aromatic), 1611 (structură aromatică), 1512 (C=C aromatic), 1364, 1300, 1221, 1063 (C-O-C), 817 (substituenţi aromatici); UV-VIS (λ_{max} (nm)): 257, 355.

$C_{38}H_{42}N_2O_{21}S$; Mr = 894.81; Randament: 90,10; p.t.° = 129-137°C; Analiza elementală (C,H,N) (Calculat/Experimental): 51,00; 4,73; 3,13/50,97; 4,70; 3,15; IR (cm^{-1}): 3434 (NH), 3330 (OH legate), 2947 (CH), 1758 (-C=O beta-lactamic), 1666 (C=O pe nucleu aromatic), 1623 (structură aromatică), 1519 (C=C aromatic), 1366, 1323, 1239, 1067 (C-O-C), 811 (substituenţi aromatici); UV-VIS (λ_{max} (nm)): 267, 358.

Diametrele zonelor de inhibiţie (în mm), corespunzătoare derivaţilor testaţi, sunt prezentate în tabelul I.

TABELUL I

Activitatea antibacteriana a derivatilor I-IV. Diametrul zonei de inhibitie (mm)

Nr. compus	*S. aureus* ATCC 25923	*S. aureus* meti-R	*S. lutea* ATCC 9341	*B. cereus* ATCC 14579	*B. subtilis*	*E. coli* ATCC 25922	*Ps. aeruginosa*	*K. pneumoniae* 1, producatoare (BLSE)
I	30	15	30	0	32	15	0	20
II	30	15	30	0	31	17	0	21
III	30	15	25	0	32	17	0	23
IV	29	14	30	0	31	10	0	15
Tetraciclina 30 μg	26	16	30	20	25	17	0	30
Cotrimoxazol 25 μg	17	20	30	19	20	21	0	21
Sulfamida 200 μg	15	0	25	20	15	15	0	14

Se constată că derivaţii I-IV sunt activi asupra tulpinilor microbiene utilizate în testări, cu excepţia *B. cereus* ATCC 14579 şi *Pseudomonas aeruginosa*; activitatea antimicrobiană este comparabilă cu cea a tetraciclinei. Nu prezintă activitate antifungică.

CONCLUZII

Au fost obţinuţi 4 derivaţi semisintetici originali ai rutozidului, prin tratarea acestuia cu 1,3-dicloro-2-propanol, 1-brom-3-cloropropan, 2-dibrom-etan, respectiv, dibrommetan, în mediu de metoxid de sodiu, şi apoi cu acidul 7-amino-cefalosporanic.

Noii compuşi au fost obţinuţi cu randamente satisfăcătoare (82-90%); aceştia se prezintă sub formă de pulberi cristaline galbene, higroscopice, solubile în apă; soluţiile apoase au un pH ≅ 7.

Compuşii au fost caracterizaţi prin stabilirea formulelor şi maselor moleculare, determinarea punctelor de topire şi calculul randamentelor.

Structura chimică a derivaţilor nou-sintetizaţi a fost confirmată prin analiză elementală C,H,N şi analize spectrale în IR şi UV.

Noii derivaţi prezintă o activitate antimicrobiană asemănătoare cu cea a tetraciclinei.

MULŢUMIRI

Autorii ţin să mulţumească Conducerii Universităţii de Medicină şi Farmacie "Gr. T. Popa" Iaşi pentru sprijinul financiar acordat în derularea Grantului Intern de Cercetare nr. 16408 / 2009

ENDODONTIC RETREATMENT IN CASE OF FAILURE. CASE REPORT

Ruxandra Mărgărit[1], Oana Cella Andrei[2]
„Carol Davila" University of Medicine and Pharmacy Bucharest
School of Dentistry

2. Department of Removable Prosthodontics

ENDODONTIC RETREATMENT IN CASE OF FAILURE. CASE REPORT (Abstract): In medical practice, clinicians come across an increased number of endodontic treatments, which, like other dental treatments, can fail. The increase in the number of endodontic treatment resulted in an increased number of failures, their management raising complex and serious endodontic problems. The endodontic retreatment of a failure is required by the increased desire to preserve the tooth on the dental arch, thus preventing the need for dental extraction that may have adverse consequences in terms of functional and psychological effect on patients. This article presents two clinical cases that required endodontic retreatment in order to avoid the complications that could ultimately require tooth extraction. The teeth in question (a mandibular first molar and an upper central incisor) having a special importance, and a physiognomic role, the endodontic retreatment consisted in covering them in porcelain fused to the metal crowns. **Keywords:** ENDODONTIC FAILURE, RETREATMENT, INCOMPLETE OBTURATION, CROWN.

Endodontic retreatment is a procedure which is done on a tooth previously endodontically treated, but whose current condition requires further endodontic treatment to achieve a successful result.

Despite the fact that the success rate of endodontic treatment is high, each clinician must be prepared to endodontically retreat the endocanalicular system, if initial treatment failes (1).

Several specialists showed that 30-50% of their clinical work is represented by endodontic retreatments.

Endodontic retreatment repeats steps of root canal treatment by coronary approach, its objective being the cleaning of the canals of irritating agents, most of them beeing microorganisms, which have survived the previous treatment or have infiltrated after therapy. Therefore, endodontic retreatment is consistent with the biological rationale of the root canal therapy and is preferable whenever possible.

CASE REPORT

Case 1: L.O. patient, a woman, showed up in the dental office complaining of pain in the right mandibular arch. Following clinical and radiological examination, it was noted that in the right mandibular region, at the level of 4.5 and 4.7 tooth, there were present two decays that required resolution only by the preparation of simple cavities filled with restorative materials. But the radiological exam showed us that, at the level of 4.6, an incorrectly performed

endodontic treatment due to the root canal filling being incomplete (fig. 1), but fortunately, has not revealed the presence of periapical pathology. Although mesial root of the tooth shows a slight curvature, suggesting a cause of endodontic treatment failure, distal root is common. Across all three canals the endodontic treatment was incomplete. We started by removing the coronary filling using a high speed spherical bur. Penetration holes into root canals were highlighted and we have performed the removing of their material fillings. Canal filling material was removed and infected root canals were disinfected using antiseptic and medicinal substances. Initially, we've resorted to a temporary root canal filling and the distal canal was filled with no problems. In an attempt to perform the treatment of the two mesial canals, their curvature constituted an obstacle. The direction of mesio-lingual canal was detected by radiological examination using a reference needle (fig. 2), ultimately being successful in achieving endodontic retreatment despite the root curvature (fig. 3), using a material based on calcium hydroxide. As a final coronal restoration a porcelain fused to metal crown was made that restores the integrity of the mandibular arch (fig. 4, 5, 6). Endodontic retreatment done on time allowed remission of clinical symptoms and also prevented the occurrence of periodontal complications. The first mandibular molar, which is an important tooth, has been saved successfully.

Fig. 6. Coronary restoration - final aspect

Case 2: A similar case of failure of endodontic treatment, is the one of T.L. patient, female, who when she came in the dental office was complainig of pain in the right upper incisor-1.1 (fig. 7). After radiological examination (fig. 8) we can see an incomplete root canal filling, what is the cause of patient's symptoms. During the stages of root canal treatment, the removing of material fillings was performed and endodontic retreatment was done thoroughly, the final result beeing illustrated in figure 8b. As coronal restoration, as in the previous case, a physiognomic porcelain fused to metal crown was done (fig. 9, 10). As a result, we prevented the loss of this front tooth, which is very important in the patient's physiognomy. Following endodontic retreatment, after a period of monitoring, there was a reduction in periapical lesion size.

DISCUSSION

As said by Mao Tse Tung, "The foundation of success is failure".

In situations when we diagnose a failure of initial endodontic treatment, there are three possible variants of solving the existing problem. The first and most indicated solution is represented by endodontic retreatment. The second option is represented by apical surgery followed by retrograde sealing of the root canal, while the last option, which is not desirable, is represented by dental extraction. The latter is necessary if the first two options can not be achieved.

The first option - non-surgical endodontic retreatment is preferable in case of endodontic treatment failures, when gaining acces to the root canals is possible. During endodontic retreatment we should do cleaning, shaping, and three-dimensional filling, with an inert filling material in all previously obturated root canals.

Some studies conducted over time, showed the presence of persistent apical periodontitis in case of endodontically treated teeth, in a proportion of 45% (2,3). The cause of persistent apical periodontitis is represented mainly by microorganisms that have survived primary endodontic treatment. This problem can be resolved by orthograde endodontic retreatment (4). During the stages of endodontic retreatment, the total removing of root filling materials is essential, so it will be possible to eliminate all residual microorganisms and to create favorable conditions for periradicular healing (5).

Studies were done on the success rate of endodontic retreatment, looking at the presence or absence of periapical lesions. Holland and colleagues have analyzed seventeen such studies (6). The conclusion is that, in case of periradicular lesions's absence, the success rate is higher, while in the cases where lesions were present, the success rate varies from a minimum of 31 , 8% to a maximum of 85%.

Friedman et al. (7) show a success rate of 100% for the endodontic retreatment of cases without periapical lesions, which suggests that in cases where infection is not present, and retreatment is done by skilled clinicians, success rate can be very high. Also Sjogren and colleagues (8), performing endodontic retreatments on 173 roots in the absence of periapical lesions, obtained a success rate of 98%. If the periapical lesion is present before starting endodontic retreatment, the success rate can be estimated at not more than 70% (7).

The second approach, apical surgery, tries to block microorganisms within the canal, through its apical seal. Leaving debris and microorganisms into the root canals is contrary to biological reasoning. Thus, surgery is a secondary alternative if endodontic retreatment is not feasible, or is contraindicated, or has failed probably due to microorganisms that invaded the periapical tissue.

If in a given situation the tooth is impossible to restore, the extraction will be recommended and an alternative replacement will be examined.

CONCLUSIONS

It is very difficult to define failure of endodontic treatment. A clear and precise definition of what success or failure is, can be said that there was not among clinicians (9).

NOUTĂȚI

STATUSUL TIROIDIAN LA PACIENȚII CU RETARD MENTAL: REZULTATELE STUDIULUI TOP-R

Un status tiroidian modificat poate afecta dezvoltarea cerebrală ducând până la retard mental. Studiul multicentric olandez TOP-R (Thyroid Origin of Psychomotor Retardation) a măsurat parametrii tiroidieni într-o cohortă de 946 pacienți diagnosticați cu retard mental de etiologie neprecizată. Rezultatele au indicat că majoritatea celor investigați aveau aceşti parametri în limitele considerate normale de laboratorul utilizat pentru testare. Împărțirea cohortei în două grupuri în funcție de utilizarea medicației antiepileptice a relevat scăderea valorilor tiroidiene pentru pacienții cărora li se administrează aceste medicamente în regim cronic (T4: 102.1±1.2 vs. 83.9±1.2 nmol/L, P<1x10(-24); FT4: 18.0±0.2 vs. 16.1±0.2 pmol/L, P<1x10(-9); T3: 1.72±0.02 vs. 1.57±0.02 nmol/L, P<1x10(-9) şi rT3: 0.37±0.01 vs. 0.27±0.01 nmol/L, P<1x10(-28) pentru pacienți fără vs pacienți cu medicație antiepileptică). Prevalența hipo şi hipertiroidismului diagnosticat de novo a fost de 5,2% respectiv 2,2%. Aceste rezultate întăresc ipoteza conform căreia medicația antiepileptică influențează nivelul hormonilor tiroidieni şi subliniază necesitatea investigării cauzelor genetice ale retardului mental în raport cu statusul tiroidian. CHEMICAL COMPOSITION OF ESSENTIAL OIL OBTAINED FROM ROMANIAN FENNEL FRUITS (Abstract): For therapeutical purposes, fennel (*Foeniculum vulgare* Mill.), an important aromatic plant, is used for its expectorant, antispasmodic, carminative and diuretic properties. The chemical composition, especially of the volatile fraction, depends on the origin of the plant, and the ecological and environmental conditions in which it grows. **Aim**: To determine the chemical composition of the volatile fractions obtained from fennel fruits (*Foeniculum vulgare* Mill.) available on the Romanian market. **Material and methods**: The essential oils obtained from dried fruits by hydrodistillation have been characterized by using gas chromatography and mass spectroscopy (GC-MS). **Results:** In all oils, the main components were: trans-anethole (9.72-56.57%), fenchone (7.72-34.66%) and estragole (4.69 - 49.04%). **Conclusions**: The essential oil from fennel samples showed an inadequate chemical profile for aromatherapy purposes. **Key words**: ESSENTIAL OILS, *FOENICULUM VULGARE*, CHEMICAL COMPOSTION

Originar din bazinul Mării Mediterane, anasonul dulce sau feniculul (*Foeniculum vulgare* Mill.) este o binecunoscută plantă medicinală şi condimentară folosită în întreaga lume, fiind cultivată pe scară largă în toată Europa, Asia şi în unele zone din Africa şi din America de Sud.

Principalele efecte terapeutice atribuite feniculului sunt cele expectorante, carminative, spasmolitice, galactagoge, estrogen-like, vermifuge şi, în ultimul timp, antioxidante. Aceste efecte sunt în mare măsură determinate de prezenţa în fructe a uleiului volatil (1, 2, 3).

Cel mai adesea, fructele de fenicul sunt recomandate în tratamentul unor tulburări dispeptice sau al unor afecţiuni respiratorii superioare. De asemenea, aceste fructe sunt componente ale unor produse farmaceutice destinate calmării colicilor infantile sau ale unor siropuri pediatrice antitusive.

În industria farmaceutică, uleiul de fenicul constituie cea mai importantă sursă de obţinere a trans-anetolului, iar în industria alimentară, se utilizează la aromatizerea produselor de panificaţie, a preparatelor din carne, a diferitelor sosuri sau a băuturilor alcoolice şi nealcoolice.

Este cunoscut faptul că tipul şi cantitatea componentelor active, prezente în drogul vegetal, în special pentru fracţiunea volatilă, variază în funcţie de o serie de

factori endogeni şi exogeni, precum: subspecia, condiţiile pedoclimatice în care se dezvoltă planta ori modalitatea de uscare şi de obţinere a fracţiunii volatile (1, 3).

Oficinale sunt uleiurile volatile obţinute de la *Foeniculum vulgare* Mill. ssp. *vulgare* var. *dulce* (care conţine 1-10% fenconă, 3-10% estragol şi 80-90% t-anetol) respectiv, de la *F. vulgare* ssp. *vulgare* var. *vulgare*, care pe lângă 50-75% t-anetol, mai conţine 2-5% estragol şi 12-33% fenconă (4).

Plecând de la acest aspect, ca şi de la faptul că între proporţia/tipul de componente active şi acţiunea biologică a produsului vegetal există o relaţie de directă proporţionalitate, ne-am propus studiul comparativ al fructelor de fenicul care circulă pe piaţa farmaceutică românească, din perspectiva fracţiunii lor volatile în scopul stabilirii compoziţiei chimice şi evidenţierii posibilelor diferenţe între acestea. Fructele de fenicul oferite în farmacii provin de la var. *dulce*.

MATERIAL ŞI METODĂ

Cele 7 mostre de fenicul supuse cercetărilor au fost constituite din produs vegetal (recoltă 2007) provenit din zone diferite ale României (Ardeal, Banat, Muntenia, Moldova).

Studiul fitochimic al probelor investigate s-a realizat prin analiza chimică cantitativă şi calitativă (GC/MS) a fracţiunii volatile.

Izolarea şi determinarea cantitativă a fracţiunii volatile s-a realizat prin hidrodistilarea timp de 4 ore a materialului vegetal uscat. Conţinutul în ulei volatil al produsului vegetal s-a exprimat procentual (ml ulei volatil la 100 g produs vegetal).

Compoziţia chimică a uleiului volatil a fost stabilită prin analiza gaz-cromatografică cuplată cu spectrometrie de masă (GC-MS) în următoarele condiţii:

Gaz-cromatograf HP 5890 series II; **Spectrometru de masă** HP 5971; Coloană **cromatografică** capilară (cross linked methylsilicone gum): HP-5 MS (30 m x 0,25 mm x 0,25 μm); Faza mobilă heliu 1 ml/min; **Temperatura injector** 260ºC; **Temperatura detecto**r 280ºC; **Regim de temperatură**: iniţial 35ºC, apoi creştere cu 10ºC/min. de la 35ºC la 260ºC (2 min. constant); **Volum injectat**: 0,1 μl ulei volatil. Identificarea substanţelor din probele analizate gaz-cromatografic s-a făcut pe baza comparaţiei între spectrul de masă din vârful peak-ului şi spectrele din biblioteca Wiley (5).

REZULTATE ŞI DISCUŢII

Urmărind aspectul organoleptic al celor 7 mostre de fructe de fenicul (fig. 1) am putut constata că mărimea, greutatea şi culoarea lor variază, unele dintre ele fiind impurificate cu fragmente de tulpină (probele 2, 5, 6).

Caracteristicile macroscopice ale fructelor de anason dulce şi randamentele la extracţia uleiurilor volatile sunt prezentate în tabelul I.

Pentru probele investigate există o variaţie importantă şi destul de largă a conţinutului în ulei volatil (2,6-9,52%); cu excepţia probelor de la Oradea şi Râmnicu Vâlcea, toate celelalte corespund cerinţelor FR X (min. 3,5% ulei volatil) (7).

Rezultatele analizei GC-MS a fracţiunilor volatile investigate sunt redate în tabelul II.

Compuşii majori identificaţi în toate probele au fost trans-anetolul, fencona şi estragolul, caracteristici uleiului volatil de fenicul; acestora li s-a adăugat limonenul, care în proba de la Vâlcea ajunge la 19%.

15.44	Δ-cadinen	-	-	0.07	-	-	-	-
16.73	trans-izodilapiol	-	-	0.21	-	-	-	-

Comparând aceste valori cu prescripţiile existente în Farmacopeea Europeană ed. a 5-a (în vigoare la momentul respectiv) (8), situaţia se prezintă conform celor redate în tabelul III.

După cum reiese din datele prezentate, nici una din probele de fructe nu a furnizat un ulei volatil care să se încadreze în cerinţele Farmacopeei Europene în ceea ce priveşte conţinutul în fenconă, estragol şi trans-anetol. Faţă de reglementările menţionate, aromaterapia (6) vine şi ea cu o serie de precizări şi cerinţe, dar acestea nu sunt îndeplinite, după cum vedem, de nici una din probele de fructe analizate.

Dacă surplusul de estragol (peste 4%, cu excepţia fructelor de la Râmnicu Vâlcea al căror ulei volatil conţine 49%) nu impietează asupra efectului expectorant, mucolitic, antiinflamator, gastro-şi bronhospasmolitic, psihostimulant, conţinutul ridicat în fenconă al uleiurilor volatile obţinute din fructele incluse în studiu aduce în sine, la administrare internă, un efect neurotoxic. Substanţa intră în categoria psihotropelor, care în doze mici sunt psihostimulante (prin modificările de metabolism cerebral pe care le induce) dar care, în doze mari dezvoltă neurotoxicitate; totodată, fencona este şi avortivă.

TABELUL III

Compoziţia probelor de ulei de anason dulce (recolta 2007) şi valori indicate în Ph. Eur. 5

Proba	Proveniența	%

Cerințe aromaterapie		0.5-5	max. 4	55-85

CONCLUZII

Dacă fructele de anason dulce sunt destinate extracţiei uleiului volatil la scară industrială, anterior acesteia trebuie analizată compoziţia chimică şi conformitatea acesteia cu cerinţele Farmacopeei Europene în vigoare.

ENZYME-ASSISTED PURIFICATION OF DENATURED ATELOCOLLAGEN, USING PRONASE AS SCAVENGING AGENT

S.S. Maier, Vasilica Maier, M. Popa, Cristina Mihaela Ignat
"Gh Asachi" Technical University of Iaşi

ENZYME-ASSISTED PURIFICATION OF DENATURED ATELOCOLLAGEN, USING PRONASE AS SCAVENGING AGENT (Abstract): Collagen liquid-crystal characteristics can be exploited in advanced applications, like microelectromechanical systems (MEMS), collagen-silica biohybrids or intelligent substrates for tissue engineering. Such applications necessarily require high purity of the collagen colloidal solutions, in terms of macromolecular unitary composition, which is equivalent to almost zero poydispersity. In this work a protocol for the enzyme-assisted removal of non-triple helical polypeptide entities in atelocollagen solutions was conceived, using pronase as scavenger, in the presence of poly(ethyleneglycol) (PEG 10000) as a crowding agent, trimethylamine-N-oxide dihydrate, (TMAO) as kosmotropic agent and anhydrous sodium sulfate as anti-chaotrope salt. Unusually high enzyme concentration (3 : 100 w/w 5 U/mg Pronase : total dry protein) imposes the triple-helix integrity protection, which was achieved by means of protective adjuvants. The adjuvant agents mixture comprising the crowder, the kosmotrope and the anti-chaotropic salt, was formulated according to the Design of Experiments (DOE) principles. The crowding agent represents the key factor in modulating pronase hydrolytic action upon atelocollagen substrate. The optimal adjuvant mixture tested in order to confirm the model validity had the composition: 0.675 PEG, 0.200 TMAO, 0.125 Na_2SO_4 (mass fractions). The proposed protocol is suitable for purifying medium and large quantities of atelocollagen previously solubilized through an alkali-enzyme technique. **Key words**: ATELOCOLLAGEN, PURIFICATION, ENZYME-ASSISTED, PRONASE, CROWDING AGENTS, KOSMOTROPES

As a strong disymmetric biopolymer and having a remarkable intrinsic stiffness, type I collagen self-associates to give chiral nematic phases (liquid-crystals), especially in confined spaces arising from protective concentrations of pure colloidal protein acidic solution, exceeding 80 mg/mL DM. The resulting mesomorphic state offers an important support in a wide variety of applications, mostly in the so-called "Lilliput structures and technologies", e.g. in generating microelectromechanical systems (MEMS) (1). An interesting series of hybrid materials, such as collagen-silica biohybrids, can be also constructed based on collagen aggregates templates (2). This kind of advanced applications however requires medium to large amounts of highly pure, triple-helical intact collagen, in native state or telopeptide deprived, able to participate in long-range self-organizing interactions. Besides, the biomedical applications require non-immunogenicity and morpho-structural stability under *in-vivo* conditions.

All atelocollagen-obtaining techniques starting from natural sources lead to a large polydispersity of solubilized molecules characteristics, both at laboratory scale and at plant scale, at most. "Screening" such a complex colloidal system, to isolate minimally denaturated, intact triple-helical atelocollagen macromolecules, can be done by

various physicochemical methods. This paper focuses on a procedure, feasible at large scale, able to scavenge atelocollagenic sols by enzymatically degrading all the denaturated protein molecules, resulting in a mixture of "undamaged" atelocollagen molecules and of easily ultrafiltrable polypeptides. The protocol can be applied in a stand-alone purifying operation, or can be adjusted, to enhance the clasic pepsin – papain solubilizing techniques of collagenic sources.

In the main, the proposed scavenging technique is based on the limited cleavage ability of proteolytical enzymes, other than collagenase, to hydrolyze the peptide bonds inside the native helical region of collagen macromolecule, and even of chemicaly non-altered α-chains decoupled from the triple helix. The only portions of fibrillar collagen that can be split up or divided by usual proteases are the telopeptides, placed at both ends of the macromolecule. Telopeptides accelerate the linear and lateral assembly of collagen fibrils, both *in vivo* and *in vitro*, but do not provide fibrillogenesis competency by themselves. So, they are unessential in supramolecular self-assembly (3) or in long-range physicochemical interactions of atelocollagen (4), but are involved in nucleation (5), the first step in supramolecular structuring. Because telopeptides represent the sites of collagen immunogenicity (6), they must be removed in all xenogenic biomedical applications.

Commercial preparations marked as Pronase represent complex mixtures of endopeptidases (serine proteases and metalloproteases) and exopeptidases (carboxypeptidases and aminopeptidases) isolated from

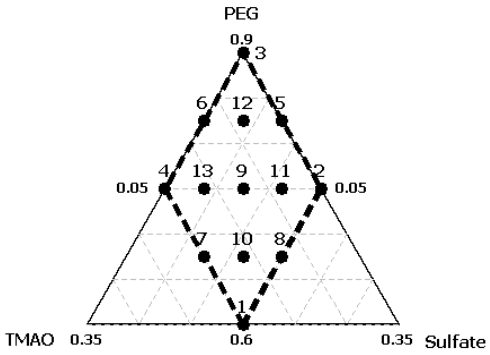

Fig. 1. The experimental design of tertiary adjuvants mixture

Streptomyces griseus. The product is free of nucleases, but comprises alkaline phosphatases and 20% calcium acetate (7). It exerts proteolytic activity upon both denatured and native proteins, which in general are broken down into individual amino acids. Pronase inhibiting and inactivating is very difficult, because of its complex composition, but all included proteases can be removed by ultrafiltration from atelocollagen solution, due to the fact that the molecular weights of individual components range between 20 and 60 kDa. The optimum pH range is between 7.0 and 8.0, but the preparation is very stable in the pH range of 6.0 to 9.0. Outside the pH range 4.0 to 10.0, pronase is unstable. The optimum temperature lies in the range of 40 to 60°C. Even in dilute solutions, pronase is not very temperature sensitive; it loses activity at 80°C, an unfeasible temperature in collagen processing.

Treating alkali-enzyme solubilized collagen with Pronase guarantee the spliting-off of both telopeptides (5), with minimal impact on triple helical domain, in the context of complete hydrolysis of denaturated forms of collagen and of macromolecular subfragments detached from the triple-helix (alpha and beta chains). Comparing to the enzymes used in the solubilizing step, tipically pepsin or papain, pronase cuts the telopeptides in the closest position to the helical region (4). This kind of action is important in the obtaining hypoimmunogenic atelocollagen, but slows down all the assembly processes.

Supplemental precautions have to be taken when working with Pronase on collagen colloidal solution, in order to modulate the proteolytic action, and to limitate parasitic cleavage of peptide bonds. PH lower than optimal and higher ionic strength are the simplest ways to modulate Pronase action, but cannot guarantee the avoidance of unwanted hydrolysis. To prevent extended attack on intact atelocollagen macromolecules, which can intervene both before and after the main telopeptide cleavage action, some kosmotropes and macromolecular crowding agents, together with anti-chaotropic salts must be added to the starting colloidal solution, during a preliminary conditioning step. The kosmotrope and the crowding agent prevent the destructuring of telopeptide- deprived triple-helix, during the final solution processing (pumping, settling/decanting, filtering). According to some authors (8), in dilute solutions and in the presence of crowding agents, the hydrolytic or degradative reactions are likely to be somewhat hindered. The antichaotropic salt preserves the spatiality of solubilized atelocollagen in the presence of the calcium acetate, an active lyotropic salt introduced in the solution by the Pronase product, during the whole period before ultrafiltration, when the calcium acetate is removed together with the antichaotropic salt. Because the majority of proteases included in Pronase require calcium ions to become active, a highly soluble, non-lyotropic calcium salt must be added in the conditioning step.

MATERIALS AND METHODS

The primary atelocollagen solution was obtained starting from newborn pigskin, pursuing a 52-operation plant-scale proce-

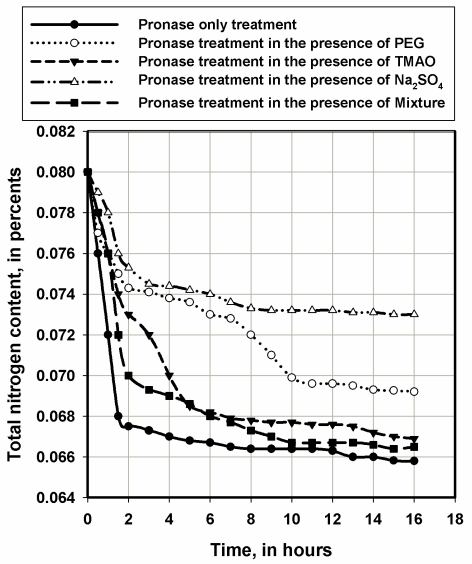

Fig. 2. Time evolution of total nitrogen content in the processed atelocollagen sol

dure, based on alkali pre-treatment, papain solubilization / refining and acid resolubilization processes, resulting in a concentrated impure, acidic atelocollagen solution, with slightly variable characteristics from one batch to another (1.6 ÷ 1.8% DM, 1.2 ÷ 1.35% protein content, aprox. 75 g protein / 100 g DM, pH 3.1 ÷ 3.3, global isoelectric pH range 4.12 ÷ 4.16, no sediment after 30 minutes centrifugation at 8000 g RCF).

Pronase was purchased from Fluka (Pronase E, Protease from Streptomyces griseus, P 81750, CAS 9036-06-0, 5 U / mg).

The crowding agent – 10 kDa poly(ethylene glycol) (Fluka P 81280, CAS 25322--68-3) was choosen as crowding agent, because it makes a good compromise between confining (9) and crystallizing (10) effects induced in protein solutions.

The kosmotrope (trimethylamine-N-oxide dihydrate, TMAO, Fluka P 92277, CAS 62637-93-8) was choosen from the nonionic class, due to its minimal electrostatic interference with collagen; its main effect is the decrease of dielectric constant near the surface of triple-helix, by a thinning effect

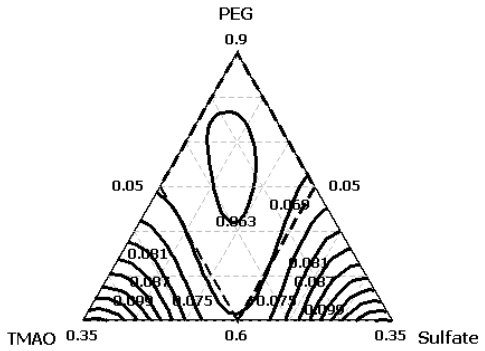

Fig. 3. The dependence of total nitrogen content of Pronase processed atelocollagen sol on the adjuvants mixture composition.

upon the attached double layer. As a consequence, the intra- and inter-catenary hidrogen bridges increase their satability, in the virtue of long-range spatial ordering of the solvent (the water). TMAO is the most efficient in the nonionic kosmotrope series (surpassing betaine, sarcosine, proline, trehalose, sucrose, glycerol and sorbitol) (11). At high concentrations (over 0.4 M) (12), kosmotropes induce collagen precipitation. Supplementary, they slow down the enzyme hydrolysis. This is why TMAO molar fraction in atelocollagen solution must be strictly controlled.

The adjuvant agents mixture comprising the crowder, the kosmotrope and the anti-chaotropic salt (sodium sulfate), was formulated according to the Design of Experiments (DOE) principles. Figure 1 and table 1 summarize the experimental design matrix.

The general experimental procedure was designed in order to identify and quantify the factors affecting the scavenging of atelocollagenic sols by removing the protein forms susceptible to pronase hydrolyze. To achieve rapid hydrolytic effects, a high Pronase to substrate ratio was used (3 : 100 w/w 5 U/mg Pronase : total dry protein), comparing to ratios usually prescribed (1 : 100, according (13)). The proposed scavenging protocol comprised the following steps:

1. diluting the raw atelocollagen sol to 0.5 % DM (below 0.4 % dry protein), to reduce viscosity ;
2. removing low molecular protein fractions, by ultrafiltering the neutralized atelocollagen sol (pH 7.5) over a 100,000 NMWL membrane ; this step is not necessarily required, but it will accelerate the overall scavenging process ;
3. sol conditioning with the adjuvants mixture (crowding agent, kosmotrope, anti-chaotrope salt ; 8% w/v mixture in a composition accordingly the experimental design matrix) and the calcium salt Pronase activator (0.05 M/dm^3 $CaHPO_4.2H_2O$ solved in the raw or ultrafiltered atelocollagen sol) ;
4. heating the sol at 38°C, under thermostatic control, in a sterilized glass reactor ; if the enzyme treatment cannot be conducted under sterile conditions, 0.01% sodium azide must be added to the sol ;
5. Pronase treatment for 16 hours, at 38°C ;
6. quick Pronase inactivation by pH lowering to 4.6 with H_3PO_4, under gentle agitation ; during acidification, the temperature is lowered to 18°C, by short bursts of carbonic ice ;
7. ultrafiltering the purified sol over a 100,000 NMWL membrane ;
8. acidification of both the purified sol and the ultrafiltered solution to pH 3.2, with HCl.

Samples of the treated sol were drawn hourly and the atelocollagen concentration was determined. Total nitrogen content of processed atelocollagen sol was determined through the Kjeldahl technique (on a VELP DK6 programmable heating digester and a VELP UDK 132 semiautomatic distillation unit), on samples equivalent to 1 g DM protein, resulted from protective evaporation (40°C, 0.02 kgf/cm^2 = 1961.33 Pa ; at this low pressure the boiling point of pure water decreased to approximately 18°C).

The individual adjuvant influence on Pronase action modulating was studied at 75% of its upper limit mass fraction considered in the mixture design matrix, respectively 5.4% w/v PEG, 1.6% w/v TMAO, 1.2% w/v sodium sulfate. The general procedure was obeyed.

The scavenging process efficiency was qualitatively proved by comparing the HPLC chromatograms of the raw and the purified atelocollagen sols. An Agilent Zorbax Bio Series GF-450 gel filtration column (9.4 x 250 mm) was made use of. The lyophilized sol samples were redissolved in sodium phosphate buffer at pH 7.5, up to a concentration of 0.2 mg/mL ; 100 mL of redissolved sol was injected and then eluted with the same buffer, at 1 mL/min flow rate. The UV absorption was recorded at 215 nm. At this wavelength, the detection limit of quasi-native atelocollagen is above 2 mg (in good accordance with (14). The column was calibrated with High Molecular Weight Range SIGMA Marker (PN S8320), reconstituted in 2 ml of the same buffer type to those in which the sample was redissolved (0.2 mg/mL final protein concentration).

RESULTS AND DISCUSSION

The individual effect of adjuvants on Pronase activity modulation is depicted in figure 2, comparing to the hydrolytic efficiency of Pronase-only treatment.

The measured response was the total nitrogen content of treated atelocollagen sol after the first half hour, and then every hour after. The anti-chaotropic salt has the strongest inhibitory effect on Pronase hydrolytic activity, due to ion pairing with lateral aminoacidic functions, resulting in a global increase of apparent hydrophobicity of polypeptide chains, at long range. The enzyme will difficultly spot the target sites on protein backbone, thus restraining its activity. The crowding agent seems to delay the Pronase hydrolytic activity and to limit its extent over atelocollagen substrate, probably

by increasing the packaging density of macromolecules. The kosmotrope has the minor direct effect on delaying the hydrolysis.

The study of the modulating efficacity of adjuvant mixtures revealed that the protective effect against extensive Pronase attack over atelocollagen triple-helix correctly fit in the experimental region. Figure 3 depicts the surface responses of mixture compositions, as it resulted from the mathematical model resumed in table II. The choosen extended full quartic type aprioric model was fitted using stepwise procedure. In the final accepted model, all individual adjuvants induced negative sign main effects, suggesting that increasing their mass fraction in the mixture will limit the Pronase hydrolytic activity. The major limiting adjuvant is the kosmotrope, but the anti-chaoptopic salt has a significant contribution, too. A strong sinergetic interaction between the kosmotrope and the anti-chaotrope was identified. A statistically significant extended effect, related to PEG component, suggests that the crowding agent represents the key factor in modulating Pronase hydrolytic action upon the atelocollagen substrate. Summation of the linear main effect (-0.0228.PEG) and the nonlinear extended effect (0.0935/PEG) indicates that the PEG mass contribution to the mixture must be optimized, in order to attain an imposed hydrolytic action. The nonlinear 1/PEG term indicates that the mechanism of Pronase activity modulation by PEG crowder is not purely physical *i.e.* governed by spatial confining only, but also involves chemical interactions, at least at high PEG concentrations.

The modelled effects of individual component mass contribution on modulating Pronase activity are depicted in Figure 4. The most influential constituent is PEG; the other two partners seem to act antagonically towards PEG. In order to obtain a maximal Pronase hydrolytic effect, PEG mass contribution to the adjuvant mixture must not exceed 25% of its accepted interval limits (see figure 4, in correlation to the header of table I), but the other two components mass contribution must exceed 75% of their own accepted interval limits. Therefore, based on the informations offered by Cox response trace plot (figure 4), the optimal adjuvant mixture tested in order to confirm the model validity have the composition: 0.675 PEG, 0.200 TMAO, 0.125 Na_2SO_4.

The modulating effect corresponding to the optimal mixture composition is depicted in figure 2. It is obvious that this mixture is able to recover the individual components inhibitory effects.

The confirmation of the scavenging effect of Pronase treatment is revealed in figure 5. Comparing to the raw atelocollagenic

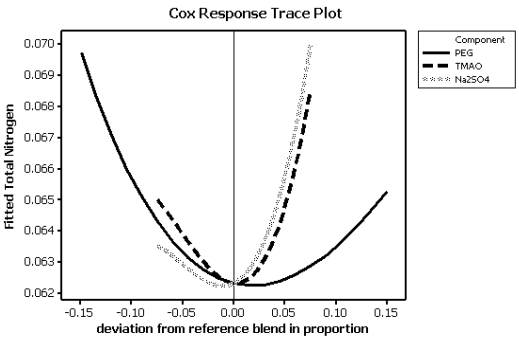

Fig. 4. The individual effects of the mixture components on Pronase activity modulating

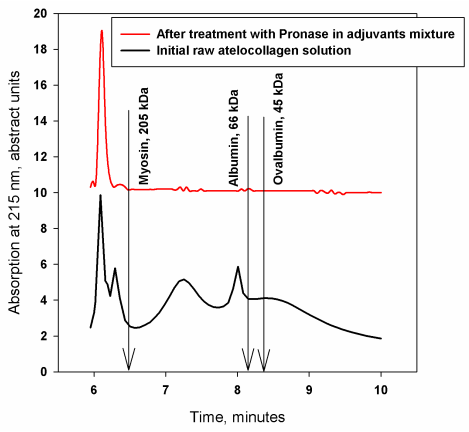

Fig. 5. Comparison between the chromatograms of the raw and the purified atelocollagen sols

sol, after six hours of protected enzyme hydrolysis, the peaks corresponding to molecular weights lower than those of telopeptides-deprived triple-helix dissapeared, but the peak associated to the heavier molecular aggregates preserved its relative amplitude. This confirms the efficiency of atelocollagen protection using optimal mixture of PEG crowder, TMAO kosmotrope and Na_2SO_4 anti-chaotope. The broad peaks, positioned in the raw atelocollagen sol chromatogram, at medium and at low molecular weights, correspond to the denaturated and hydrolyzed collagen forms. These polypeptides were completely hydrolyzed by Pronase.

In figure 5, the position of three known proteins included in the SIGMA marker are shown by arrows, to indicate the range of protein forms in the studied atelocollagen sols. The respective positions, on the time scale are those obtained by the time the Zorbax GF-450 column was calibrated.

CONCLUSIONS

In a protective regime, a certain scavenging effect of Pronase on denaturated atellocolagen colloidal solutions can be achieved.

By sol conditioning with 8% w/v of an optimal mixture including a crowding agent (PEG 10000, at a mass participation fraction of 67.5%), a kosmotrope (TMAO dihydrate, 20% mass fraction) and an anti-chaotropic salt (anhydrous sodium sulfate, 12.5% mass fraction) the Pronase hydrolytic efficacity is minimally altered, but the protective effect over the atelocollagen triple-helix is ensured.

In conditioned sols, Pronase hydrolytically breaks down all the polypeptides resulted from the collagen solubilizing processes, splits up the remaining telopeptide portions, but do not attack the triple-helical domain.

The scavenging protocol described in the paper is able to drastically reduce the polydispersity of atelocollagen colloidal solution, thus offering a way to produce sufficient quantities of stiff, highly self-similar macromolecules to find particular uses in advanced scientific fields, such as in nematic applications, or in scaffolds generation.

NOUTĂŢI

Denervarea simpatică renală prin cateter (DSRC) o soluţie terapeutică în HTA rezistentă

Progresele recente în tehnologia cateterelor intravasculare au permis punerea la punct a unor catetere purtătoare de sonde de radiofrecvenţă care permit DSRC, metodă lansată în 2009. Primul studiu multicentric randomizat pentru DRSC, denumit Simplicity, a inclus 106 pacienţi cu o HTA rezistentă (definită printr-o TA sistolică - TAS > sau egală cu 160 mm Hg (150 mm Hg la diabetici), tratată cu cel puţin 3 antihipertensive şi confirmată după o supraveghere ambulatorie de 2 săptămâni). În grupul DSRC protocolul terapeutic a constat în 4-6 şedinţe de radiofrecvenţă de putere mică, de-a lungul celor două artere renale. Evaluarea PAS s-a făcut după 6 luni la 103 pacienţi, rezultatele fiind extrem de favorabile : TAS a scăzut în medie cu 32 mm Hg, în timp ce TA diastolică - TAD a scăzut cu 12 mm Hg ($p=0,0001$). TAS şi TAD practic nu au variat în grupul control (+ 1 mm Hg/0 mm Hg ; $p<0,0001$). Şi din punct de vedere al altor criterii DSRC s-a dovedit a fi benefică : TA automăsurată la domiciliu (diferenţă 22/12 mm Hg ; $p<0,0001$), TA măsurată ambulator 24 ore a arătat o scădere medie de 11/7 mm Hg ; atingerea unei valori optime de 140 mm Hg (39% faţă de 6%) ; scădere mai mare de 10 mm Hg a TAS (84% faţă de 35%, $p<0,0001$ în ambele cazuri ; scăderea posologiei (20% fa?ă de 6%). În această serie, totuşi scurtă, de cazuri, efectele secundare ale DSRC au fost limitate la dureri dorsale prezente la un singur pacient şi tulburări vagale ce au necesitat administrare de atropină în 13% de cazuri. OZONE THERAPY EFFICIENCY AND GEROVITAL H3 AS AN ADDITIONAL WAY TO THE COMPLEX TREATMENT OF PERIODONTAL DISEASE (Abstract): The authors present the methodology of the ozone use and a method of chemical stimulation with Gerovital H3, applied within a complex therapy of the periodontal disease. Its efficiency is argued by the clinical images taken from the oral cavity and radiographic images of the patients with periodontal disease in various evolution stages. **Results**: The images reveal the possibility of stopping the progressive disease and the improvement of the clinical aspect of the marginal periodontium. The X-ray images reveal the possibility of re-mineralization of the alveolar bone and healing processes in certain areas, at different periods of time. **Conclusions**: Favorable results are associated firstly with compliant patients that benefit of treatment planning elaborated after a correct evaluation of the clinical situation. The results prove the strong oxidant and antibacterial effects of ozone as well as the regenerative and biotrophic action of Gerovital H3 in periodontal tissues for patients with early and advanced periodontal disease.
Key words: OZONE, GEROVITAL H3, PERIODONTAL DISEASE

Parodontita marginală cronică este responsabilă de pierderi dentare datorită afectării aparatului de susţinere.

Atunci când dorim reabilitarea funcţională a dinţilor afectaţi trebuie să ne gândim în primul rând la controlul infecţiei bacteriene dar mai ales la repararea defectelor rezultate în urma activităţii bolii (1).

Există numeroase studii care susţin capacitatea de regenerare în urma utilizării diverselor tehnici prin adiţie osoasă şi regenerare tisulară ghidată, însă regenerarea nu este întotdeauna prezentă sau completă. Există şi alte metode de tratament care aduc îmbunătăţiri ale situaţiei clinice precum şi a nivelului osos. Abordările predominant mecanice în ceea ce priveşte tratamentul au dus la rezultate deseori dezamăgitoare datorită neputinţei clinicienilor de a realiza un control adecvat al patogenilor parodontali precum şi a neputinţei sau reavoinţei pacienţilor de a se supune măsurilor necesare pentru prevenirea reapariţiei bolii.

Folosirea agenţilor antiinflamatori şi/sau antiinfecţioşi în tratamentul parodontitei a fost făcută frecvent în mod empiric. Există dovezi care arată că adăugarea unei terapii antiinfecţioase corecte la tratamentul tradiţional poate îmbunătăţi în mod substanţial rezultatele clinice şi poate reduce nevoia de proceduri chirurgicale costisitoare.

Un tratament al parodontopatiei prin mij-

loace care să fie eficiente din punct de vedere al costului - cum este ozonoterapia asociată cu terapia de stimulare chimică cu Gerovital H3 – poate oferi populaţiei, care nu are acces la servicii medicale supraspecializate datorită lipsei de resurse financiare, un mijloc eficient de a menţine o dentaţie funcţională pentru o perioadă lungă de timp. Iată de ce ne-am propus să aplicăm în clinică atât ozonul cu efect antimicrobian în pungile parodontale şi de stimulare a troficităţii la nivelul ţesuturilor parodontale cât şi gerovitalul aplicat prin infiltraţii locale.

MATERIAL ŞI METODĂ

Au fost luaţi în studiu pacienţi cu boală parodontală cronică a adultului aflaţi în diverse stadii de evoluţie la care terapia convenţională de înlăturare a acţiunii factorilor etiologici locali şi generali a fost asociată cu şedinţe de insuflaţie cu ozon în pungile parodontale şi infiltraţii cu Gerovital H3, în cure de tratament.

Expunerea la ozon a pungilor parodontale s-a efectuat în trei şedinţe la interval de o săptămână. In aceeaşi perioadă de timp s-au realizat infiltraţiile cu Gerovital H3. Infiltraţiile au fost efectuate cu soluţii de Gerovital H3 în doză de un mililitru pe şedinţă injectat cu seringi cu ac subţire utilizate pentru injectarea insulinei la diabetici, la interval de 2 sau 3 zile, într-un număr cuprins între 8 şi 12 şedinţe în raport cu gradul de afectare parodontală şi de modalitatea de răspuns al pacientului.

Curele de tratament au fost reluate la 6 luni. La fiecare cură s-a mărit numărul şedinţelor de expunere la ozon cu una, în funcţie de toleranţa individuală.

La începutul fiecărei cure cu Gerovital H3, s-a testat produsul epicutanat sau intradermic, pe antebraţ, pentru a preveni reacţiile alergice.

De la loturile aflate în tratament redăm imagini preluate din cavitatea orală şi imagini radiografice.

Caz clinic nr. 1 :

În fig. 1 se observă aspectul clinic al arcadelor dentare ale unei paciente în vârstă de 42 de ani cu boală parodontală cronică stabilizată. Se observă absenţa proceselor inflamatorii la nivelul mucoasei gingivale după trei cure de tratament. Se observă şi prezenţa cariilor de suprafaţă radiculară oprite în evoluţie şi remineralizate în urma expunerii lor la ozon.

Caz clinic nr. 2 :

În fig. 2 se observă aspectul clinic al arcadelor dentare la un pacient în vîrstă de 54 ani, cooperant în efectuarea tratamentului. Se observă aspectul normal al culorii gingiilor, lipsa depozitelor şi a inflamaţiei, precum şi mineralizarea produsă în urma expunerii la ozon.

Caz clinic nr. 3 :

Imaginile preluate de la cazul clinic nr. 3 reprezintă statusul parodontal la momentul prezentării pacientului P.R. în vârstă de

Fig. 1. Cazul clinic nr. 1

Fig. 2. Cazul clinic nr. 2

Fig. 3. P.R., 53 ani. Aspect radiografic (iniţial)

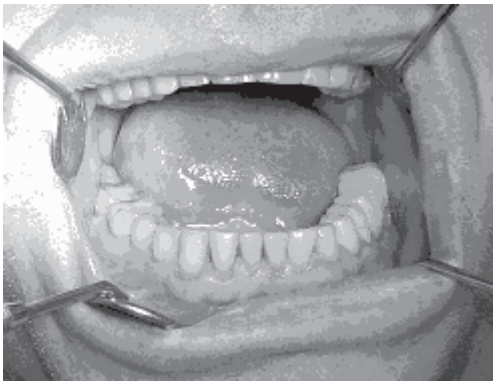

Fig. 5. P.R., 53 ani. Aspect clinic după 5 cure de tratament

53 ani, cu boală parodontală cronică avansată (fig. 3) şi aspectul după cinci cure de tratament, la trei ani de la prezentare (fig. 4).

După un interval de 30 luni se observă o evoluţie favorabilă manifestată prin oprirea evoluţiei bolii, manifestată prin absenţa proceselor inflamatorii, reducerea profunzimii pungilor parodontale şi creşterea densităţii osului alveolar.

Caz clinic nr. 4 :

Imaginile preluate de la cazul clinic nr. 4 reprezintă statusul parodontal la momentul prezentării al pacientei I.J. în vârstă de 55 ani, cu boală parodontală cronică avansată (fig. 6) şi aspectul după cinci cure de tratament, la trei ani de la prezentare (fig. 7).

În momentul prezentării la tratament pacienta prezintă resorbţie osoasă orizontală şi pungi infraosoase asociate cu zone de demineralizare la nivelul arcadei mandibulare şi atrofia crestei alveolare maxilare care afectează stabilitatea protezei superioare. Concomitent cu terapia etiologică

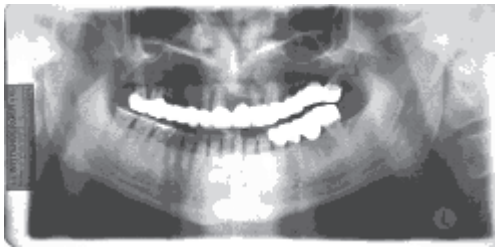

Fig. 4. P.R., 53 ani. Aspect radiografic după 5 cure de tratament

şi de imobilizare a dinţilor arcadei mandibulare, s-au efectuat patru cure de tratament cu ozon în pungi şi infiltraţii cu gerovital. După un interval de 24 luni se observă reducerea profunzimii pungilor osoase şi creşterea densităţii osoase atât la nivelul arcadei mandibulare cât şi la nivelul arcadei maxilare.

Caz clinic nr. 5 :

Pacientul A.M., în vârstă de 42 ani s-a prezentat cu diagnosticul de parodontită marginală cronică profundă. Pe imaginea radiografică (fig. 8) în momentul prezentării se observă liză osoasă orizontală şi verticală asociată cu reducerea densităţii osoase la nivel maxilar şi mandibular. Concomitent cu tratamentul etiologic şi corectiv local, au fost aplicate patru cure de ozonoterapie şi infiltraţii cu Gerovital H3 la intervale de 6 luni. Imaginea radiografică la un interval de 24 luni (fig. 9) arată creşterea densităţii osoase şi reducere profunzimii pungilor osoase. Imaginea radiografică la un interval de 48 luni (fig. 10) evidenţiază refacerea aproape completă a trabeculaţiei osoase.

DISCUŢII

Imaginile preluate de la pacienţii care au cooperat în efectuarea curelor de tratament dovedesc posibilitatea opririi în evoluţie a bolii parodontale cronice a adultului indiferent de faza clinică în care este aplicat tratamentul şi posibilitatea refacerii ţesuturilor parodontale, în special la nivel osos, prin mijloace terapeutice conservative.

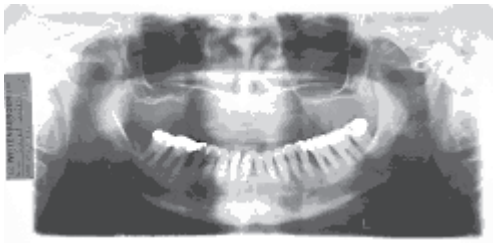

Fig. 6. I.J., 55 ani. Aspect radiografic (iniţial)

Azarpazhooh şi Limeback constată că, deşi studiile *in vitro* demonstrează potenţialul promiţător al ozonului în stomatologie, studiile clinice necesită metode de măsurare şi analiză standardizate pentru a evalua potenţialul real al ozonului ca modalitate terapeutică în stomatologie (1,2). Aplicarea terapiei cu ozon în pungile parodontale se dovedeşte a fi eficientă în distrugerea florei bacteriene parodontopate (3) şi oferă posibilitatea ţesuturilor parodontale de a se reface, stimulate atât de expunerea la ozon cât şi de curele de tratament cu Gerovital H3. Terapia cu ozon în boala parodontală (4) este eficientă şi lipsită de riscuri dacă este asociată cu precauţii şi măsuri de protecţie. Utilizarea empirică a ozonului a contribuit la limitarea utilizării lui în stomatologie în unele ţări. Există dovezi care scot în evidenţă o sensibilitate deosebită a sistemului bronho-pulmonar la ozon deoarece la acest nivel există cantităţi minime de antioxidanţi, ceea ce face celulele mucozale extrem de vulnerabile la oxidare ; celulele sanguine au însă o capacitate antioxidantă adecvată (1,23 – 1,83 mol/L) şi sunt capabile de a compensa orice doză de ozon cuprinsă între valorile terapeutice (10 – 20 mg/L) (5). În Clinica de Odontologie şi Parodontologie din Iaşi s-a acumulat experienţă în utilizarea ozonului în terapia stomatologică, atât în terapia cariilor simple şi complicate cât şi în boala parodontală - prima lucrare ştiinţifică fiind publicată încă din 1970 (6). Tratamentele au fost începute întotdeauna cu doze mici şi timp de expunere scurt, cu scopul de a induce pacienţilor o adaptare la stresul cronic oxidativ. Studiul de faţă prezintă o serie de cazuri clinice urmărite pe o perioadă de 2-3 ani.

Asocierea curelor de tratament cu ozon cu şedinţe de infiltraţie cu Gerovital H3 a condus la creşterea ratei de succes clinic. Eficienţa Gerovitalului H3 a fost dovedită clinic şi experimental de către Ana Aslan

fiind administrat în numeroase afecţiuni cu scopul de a încetini procesele de involuţie şi de ameliorare a stării pacienţilor suferinzi de maladii cronice degenerative (7,8). Procaina, componentă principală a Gerovitalului H3 nu prezintă toxicitate fiind hidrolizată rapid în ţesuturi, sub acţiunea enzimei procain esteraza, în acid paraaminobenzoic şi dietilaminoetanol, produşi lipsiţi de toxicitate, metabolizaţi imediat şi eliminaţi prin urină (9). Aplicarea lui în diverse forme clinice de boală parodontală este oportună întrucât procesele degenerative sunt prezente şi la nivelul ţesuturilor parodontale (10). Efectele benefice se datorează stimulării troficităţii ţesuturilor parodontale, ameliorării circulaţiei şi metabolismului local, echilibrării tonusului neuro-vegetativ tisular, efecte care conduc la refacerea parţială a zonelor tisulare afectate.

CONCLUZII

Utilizarea ozonului în cadrul tratamentului complex al bolii parodontale conduce la efecte clinice evidente manifestate prin reducerea şi dispariţia sângerării, normalizarea tabloului clinic şi reducerea pierderilor de ataşament parodontal.

Asocierea terapiei parodontale cu şedinţe de infiltraţii cu Gerovital H3 stimulează procesele de regenerare tisulară şi conduce la creşterea troficităţii ţesuturilor parodontale.

CELLULAR MEDIATED IMMUNITY REGULATION DONE BY C*HENOPODI BONI HENRICI HERBA* POLYZAHARIDES IN HENS. (Abstract) : The immunomodulatory effect of polysaharides from *Chenopodium bonus-henricus* herba was tested on adult hens. **Material and method** : Blood samples were harvested aseptically by punction of brachial vein ; ability of circulating phagocytes was assessed by the carbon particles phagocytosis test *in vitro* ; while reactivity of peripheral lymphocytes was evaluated by lymphocytes transformation assay *in vitro*. Polysaharides were dissolved in saline solution and filtered throughout Millipore. **Results** : Phagocytic indexes (at 15 and 39 minutes) are variable according to polysaharides concentration ; phagocytosis increased at 15 minutes for 40 μg/mL and 60 μg/mL, while for 30 minutes the phagocytic index decreased. In lymphocytes transformation assay, *Chenopodium bonus-henricus* polysaharides, alone, shown no stimulatory effect, and together to the classic mitogen, their influence was variable, but not statistical significant results were seen. **Conclusion** : Polysaharides have inconstant effect on phagocytosis, and mainly inhibitory role on lymphocytes proliferation. **Key words** : C*HENOPODIUM,* CELLULAR MEDIATE IMMUNITY, HENS

SCHIFF BASES OF L-LYSINE: MICROWAVE INDUCED SYNTHESIS, CHARACTERIZATION AND BIOLOGICAL ACTIVITY

SCHIFF BASES OF L-LYSINE: MICROWAVE INDUCED SYNTHESIS, CHARACTERIZATION AND BIOLOGICAL ACTIVITY (Abstract): L-Lysine, also called 2,6-diaminohexanoic acid or alpha-epsilon-diaminocaproic acid is an essential amino acid which recently is being studied for its effects in different conditions, such as: herpes infections, cold sores, osteoporosis, anxiety, migraines etc. **Aim**: This paper is focused on the synthesis of new L-lysine compounds with a potential antioxidant activity. **Material and Methods**: The chemical synthesis is microwave induced and consists in the condensation of H-Lys (Boc)-OMe hydrochloride with various benzaldehyde (3-hydroxy/4-methyl-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde and benzaldehyde) resulting the corresponding Schiff bases. **Results**: The chemical structure of the synthesized compounds was confirmed by spectral methods (IR, ^{1}H-NMR) and the antioxidant potential was evaluated by determining the anti-radical effect using the free radical DPPH and radical cation $ABTS^{\cdot+}$ assays. **Conclusions**: Following the protocol new Schiff bases of H-Lys (Boc)-OMe hydrochloride were synthesized and characterized by physico-chemical and spectral methods. The evaluation of antioxidant potential using *in vitro* methods showed that the compound synthetized by condensation with 3-hydroxy benzaldehyde is the most active. **Keywords**: LYSINE, SCHIFF BASES, ANTIOXIDANT ACTIVITY.

The role of lysine in the prevention and treatment of herpes infections and cold sores has been studied (1). It also increases the intestinal absorption of calcium and decreases its excretion by the kidney, suggesting that it might be helpful in osteoporosis (2). Lysine has also been investigated for its effects on increasing muscle mass, lowering glucose (3), improving anxiety (4) and some case reports suggest that lysine may ameliorate angina (5). Lysine acetylsalicylate has been used to treat pain and to detoxify the body after heroin use (6), while lysine clonixinate has been used to treat migraine headaches and other painful conditions (7).

It has been 150 years since the first Schiff bases (azomethine) were synthesized by *Hugo Schiff* an Italian chemist of German origin who gave the name of this class of substances and which remained in the attention of scientists because of the multitude of

applications (8). Schiff bases have shown a wide range of biological activities such as antifungal, antibacterial, antimalarial, anti-proliferative, anti-inflammatory, antiviral and antipyretic, the azomethine group being present in many natural and unnatural compounds (9). The interest on imines becomes even more pronounced in view of their easy way of synthesis and wide applicability and the presence of an antioxidant property. In order to develop new therapeutic agents derived from the amino acid L-Lysine with antioxidant effects new Schiff bases were synthetized and evaluated for their antiradical properties.

MATERIAL AND METHODS

The aromatic aldehydes (3-hydroxy/4-methyl-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde and benzaldehyde), organic solvents (*p.a.* quality) and the standard reagents used for the antioxidant tests were purchased from Sigma Aldrich Company and Fluka Company and H-Lys-(Boc)-OMe hydrochloride was purchased from Alfa Aesar Company. All solvents and reagents were used without prior purification. For monitoring the reactions TLC silica gel 60 F_{254} plates from Merck Company were used.

Chemistry

Synthesis of Schiff base. The synthesis of azomethine derivatives consists in the condensation of H-Lys (Boc)-OMe·HCl with various aromatic aldehydes (3-hydroxy/4-methyl-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde and benzaldehyde) which results in the corresponding Schiff bases (fig. 1).

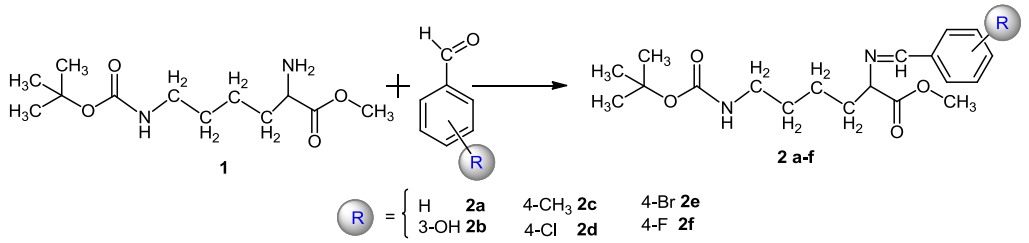

Fig. 1. Scheme of the microwave induced synthesis of lysine Schiff bases

General procedure for the synthesis of lysine Schiff bases:

The microwave induced synthesis of the products started with the suspension in a 5 ml microwave vial of 1 eq. of H-Lys (Boc)-OMe·HCl (MW = 296.79 g/mol) in 2 ml freshly distilled tetrahydrofuran and then 4 eq. of Na_2CO_3 (MW =105.99 g/mol) and 5 eq. of $MgSO_4$ (MW = 120.366 g/mol) were added under continuous stirring. Finally 1.05 eq. of different aromatic aldehydes (3-hydroxy/4-methyl-/4-chloro-/4-fluoro-/4-bromo-benzaldehyde and benzaldehyde) were added and then the vial was put into microwave reactor at 100^0C for 30 min (10, 11). The reaction was monitored by TLC, using as solvent system a mixture of dichloromethane: methanol (8:2). The unreacted benzaldehyde was removed by washing with diethyl ether and petroleum ether. At the end of the reaction, the solution was concentrated in order to remove the tetrahydrofuran.

Characterization by spectral methods. IR spectra of the synthesized compounds were recorded using a Fourier transform spectrometer, ABB-MB 3000 FT-IR MIRacle^{TM} Single Bounce ATR-crystal ZnSe,

and the studied spectral range was in the range of 4000-500 cm $^{-1}$, at a resolution of 4 cm^{-1}, 16 scans being carried out for each sample. The spectra were interpreted using Horizont program MB^{TM} FT - IR. ^{1}H-NMR spectra were registered using NMR Bruker 400 MHz spectrometer (Germany).

Antioxidant assays

DPPH radical scavenging activity. In order to evaluate the antiradical capacity against DPPH radical the samples were dissolved in DMSO to obtain a stock solution concentration of 20 mg/mL. From the stock solution there were taken different volumes (50 µL, 100 µL, 150 µL, 200 µL) which were diluted with methanol in order to obtain 200 µL. The next step consisted in adding 2800 µL methanolic solution of DPPH (0.1 mM, A_{517nm}=1.0±0.05) and the mixture was stirred and let to stand for 30 minutes in the dark, after which the absorbance was read at 517 nm against methanol used as a blank (12, 13) .

Antiradical capacity was calculated as an inhibition percentage (I%) using the formula: I% = ($A_0 - A_s$ / A_0) x 100 wherein, A_0 = the absorbance value of the 0.1 mM DPPH methanolic solution; A_s = the absorbance value of the sample, read at 30 minutes after adding the methanol solution of DPPH. For each compound the effective concentration 50 (EC_{50}) was calculated by linear regression, and vitamin E (20 mg/mL) was used as a positive control. All experiments were performed in triplicate and the results were expressed as arithmetic average ± standard deviation (SD).

ABTS radical scavenging activity. The generation of the $ABTS^{\cdot+}$ cation radical was performed by treating the aqueous solution of 2,2'-azino-bis (3-ethylbenzothiazoline-6-sulfonic acid) (7 mM) with potassium persulfate (2.45 mM). The resulting mixture was kept in the dark for 12 to 16 hours to promote the formation of $ABTS^{\cdot+}$ radical, resulting the stock solution. The stock solution of $ABTS^{\cdot+}$ was diluted with ethyl alcohol to obtain a solution with an absorbance of 0.700 ± 0.020 at a wavelength of 734 nm (14).

The samples were dissolved in DMSO to obtain a stock solution with a concentration of 20 mg/mL. From the stock solution different volumes (10 µL, 15 µL, 20 µL, 25 µL) were taken and then diluted with DMSO up to the volume of 25 µL to which 1975 µL of $ABTS^{\cdot+}$ solution were added. After 6 minutes the absorbance of the samples was read at λ = 734 nm in reference to the blank (ethyl alcohol).

The antioxidant activity was expressed as percentage of inhibition (I%) of the $ABTS^{\cdot+}$ radical cation by the following formula: I% = ($A_0 - A_s$ / A_0) x 100 wherein, A_0 = the absorbance value of the ethanolic solution of $ABTS^{\cdot+}$; A_s = the absorbance value of the sample, read at 6 minutes after the addition of $ABTS^{\cdot+}$ solution. For each compound the effective concentration 50 (EC_{50}) was calculated by linear regression, and vitamin E (20 mg/mL) was used as a positive control. All experiments were performed in triplicate and the results were expressed as arithmetic average ± standard deviation (SD).

RESULTS AND DISCUSSION

Physicochemical and spectral characterization

The Schiff bases of lysine are liquids or glues colored in different shades which vary from colorless to bright brown, very slightly soluble in acetone, ethanol, methanol, dimethylformamide (DMF) and dimethyl sulfoxide (DMSO), partially soluble in chloroform, dioxane, and insoluble in distilled water, diethyl ether and petroleum ether. The physicochemical and spectral

characteristics are listed in Table I. The presence of the absorption band characteristic to azomethine bound (-CH=N-) and the appearance of the signal of the proton from the same chemical bound confirms the structure of the synthesized compounds.

TABLE I

2f	4-F	366.20	88.38	3373 (-NH-), 2951 (CH_{Ar}), 1595 (-CH=N-), 1095 (C-F)	8.31 (s, 1H, C<u>H</u>=N), 7.79-7.85 (m, 2H, Ar-H), 7.12-7.18 (m, 2H, Ar-H), 3.97-4.03 (m, 1H, C<u>H</u>-$COOCH_3$), 3.70 (s, 3H, $COOC\underline{H_3}$) 2.94 (t, 2H, $C\underline{H_2}$), 1.86-1.78 (m, 2H, $C\underline{H_2}$), 1.53-1.40 (m, 2H, $C\underline{H_2}$), 1.30 (s, 9H, $C(\underline{CH_3})_3$), 1.21-1.10 (m, 2H, $C\underline{H_2}$)

Antioxidant activity

DPPH radical scavenging activity. The method was based on spectrophotometric determination of the capacity of inactivating the stable free radical DPPH (2,2-diphenyl-1-(2,4,6-trinitrophenyl) hydrazyl), purple, by addition of hydrogen with the formation of 2,2-diphenyl-1-(2,4,6-trinitrophenyl) hydrazine, yellow. After analyzing the data from Table II and fig. 2 we can say that the azomethine derivatives resulted from the condensation of H-Lys(Boc)-OMe·HCl with 3-OH-benzaldehyde (2b) were found to be 1.33 times more active than those of H-Lys(Boc)-OMe·HCl. As to the influence of substitution on the aro-

matic ring it was found that the radicals 4-CH_3 (2c), 4-Cl (2d), 4-Br (2e) and 4-F (2f) provided action comparable to that of the starting material. The compounds studied were, however, less active than vitamin E used as positive control.

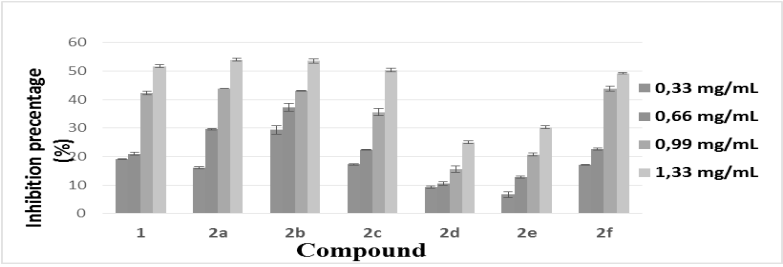

Fig. 2. The inhibition (%) of DPPH radical for 2a-f compounds at different concentrations

TABLE II

EC_{50} values (mg/mL) for the antiradical capacity against DPPH radical of derivatives 2a-f

Compound	EC_{50} mg/mL	Compound	EC_{50} mg/mL
H-Lys(Boc)-OMe·HCl	0.722 ± 0.02	**2d**	2.074 ± 0.02
2a	0.747 ± 0.06	**2e**	2.243 ± 0.03
2b	0.642 ± 0.02	**2f**	1.360 ± 0.14
2c	1.012 ± 0.01	**Vitamin E**	0,062 ± 0.023

* EC_{50} values are the average of three determinations ± standard deviation

ABTS radical scavenging activity. The antioxidants which can reduce the radical cation $ABTS^{\cdot+}$ by electron transfer mechanism are visible by the color variation from blue to yellow. From the results listed in Table III and fig. 3 it was noticed that compound **2b** was the most active synthetized product, being 2.85 times more active than H-Lys (Boc)-OMe·HCl. The azomethine derivatives have an action comparable to that of the starting material and the antiradical capacity against $ABTS^{\cdot+}$ cation radical is directly proportional to the concentration of the respective sample. In comparison with vitamin E used as positive control the studied compounds were less active.

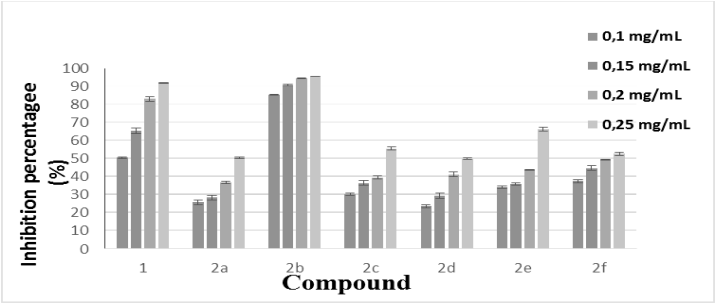

Fig. 3. The inhibition (%) of $ABTS^{\cdot+}$ cation radical for 2a-f compounds at different concentrations

TABLE III

EC_{50} values (µg/mL) for the antiradical capacity against $ABTS^{\cdot+}$ cation radical of derivatives 2a-f

* EC_{50} values are the average of three determinations ± standard deviation

CONCLUSIONS

In this study new derivatives of amino-acid lysine have been synthesized using microwave and the optimal reaction conditions for obtaining compounds in high yields and with high purity have been established. The synthesized compounds were characterized by their physical constants (yield, molecular formula, molecular weight, solubility in different organic solvents) and their chemical structure was confirmed using spectral methods such as: FT-IR spectroscopy and ^{1}H-NMR. The antioxidant potential was assessed by *in vitro* methods. Most of the studied compounds showed an improved antiradical capacity against $ABTS^{\cdot+}$ radical cation and DPPH radical compared to the starting material, demonstrating a favorable impact of structural modulation on the antioxidant effects of lysine.

NEWS

HYALURONIC ACID AS AN ADJUNCT TO SCALING AND ROOT PLANING IN CHRONIC PERIODONTITIS

The aim of this study was to evaluate the adjunctive effect of local application of hyaluronon gel following scaling and root planning in patients with chronic periodontitis. In this randomized split mouth study 33 subjects with chronic periodontitis were evaluated after full mouth scaling and root planning. In the test sites hyaluronon gel was applied immediately after scaling and root planning and one week post-therapy, the control sites were treated with scaling and root planning alone. Bleeding on probing, probing pocket depth, and clinical attachment level were recorded at baseline, 4 and 12 weeks. The results showed a significant reduction in bleeding on probing scores in both the groups at 12 weeks ($p<0.001$). The hyaluronon group showed a greater reduction in bleeding on probing ($p<0.001$). In the hyaluronon group the mean probing pocket depth at baseline was 6.33 ± 0.09 which reduced to 2.49 ± 0.51 at 12 weeks which was statistically significant ($p<0.001$). In the control group the mean probing pocket depth at baseline was 6.09 ± 1.26 which reduced to 4.36 ± 1.29 at 12 weeks which was statistically significant ($p<0.001$). The clinical attachment level measurements showed a significant difference between the groups ($p<0.001$) at 12 weeks post therapy. The conclusion of this study showed that the hyaluronic acid has a beneficial effect on periodontal health in patients with chronic periodontitis. Hyaluronic acid appears to be a suitable candidate as an adjunct to scaling and root planning in chronic periodontitis patients (Rajan P, Baramappa R, Rao NM, Pavaluri AK, PI, Rahaman SM. Hyaluronic Acid as an adjunct to scaling and root planing in chronic periodontitis. A randomized clinical trail. *J Clin Diagn Res* 2014; 8(12): 11-14).

MULTI-ANALYTIC DETECTION OF ANTIBIOTIC RESIDUES IN HONEY USING A MULTIPLEXING BIOCHIP ASSAY (Abstract): Contamination of honey may occur through the common use of antibiotics and chemotherapeutics by certain beekeepers to cure or to prevent bacterial or other bee diseases. In order to protect human health the use of antimicrobials in apiculture is usually strictly regulated or banned. LC/MS/MS is currently regarded the tool of choice for analysis of drug residues in animal-derived food. Screening methods (immunoassays and biosensors) are also required and are being developed. **Aim**: The present paper reviews one of the most recent methods for analysis of drug residues in honey and also the abridged method validation according to the criteria set by Commission Decision 2002/657/EC for simultaneous determination of drug residues in honey samples using a test panel which screens for quinolones (QNL), ceftiofur (CEFT), thiamphenicol (TAF), streptomycin (STR), tylosin (TYL) and tetracyclines (TCN). **Material and methods:** A chemiluminescence - based biochip array sensing technique has been applied. Using a multiplex approach, metabolites of CEFT, TAF, QNL, STR, TCN and TYL were simultaneously detected in honey samples. **Results and discussion:** The simultaneous immunoassays showed specificity for the target analytes. The limits of detection were between 1 µg/kg for TAF and 9 *µg/*kg for TCN. Good linearity was obtained, with determination coefficients higher than 0.980. The decision limit (CCα) and the capability of detection (CCβ) were well below established Reference Point for Action (RPA). Method applicability was demonstrated through application to various kinds of honey. **Conclusions:** Biochip array technology allows simultaneous and selective multi-analytic measurement of antimicrobials in honey at levels well below established Reference Point for Action (RPA). The performance of biochip screening method was comparable to that achieved for the confirmatory LC/MS/MS method. **Key words:** HONEY, QUINOLONES, TETRACYCLINES, DRUG RESIDUES, BIOSENSOR.

In apiculture, antibiotics are mainly used for the treatment of bacterial brood diseases, such as American foulbrood (*Paenibacillus larvae*) and European foulbrood (*Streptococcus pluton*). Oxytetracycline was the first antibiotic to be used for the control of American and European foulbrood, but other chemotherapics, such as sulfonamides, macrolides and tylosin, are also used to prevent these diseases (1). In general, the presence of drug residues in honey is banned. Therefore, it is necessary to develop sensitive analytical methods with low limits of detection (LODs) in

order to detect traces of antibiotics in honey. Some surveys show that positive samples can be contaminated by more than one class of antibiotics (2). The development and use of new sensitive multiclass methods are necessary for the simultaneous determination of antibiotics at trace levels in this matrix.

The aim of the present work was the optimization and revalidation of a sensitive method for the simultaneous determination of veterinary drug residues belonging to several classes including CEFT, TAF, QNL, STR, TCN and TYL. The proposed method allows simultaneously screening of parent molecule and major metabolites in honey samples and detects veterinary drugs at low concentration levels (<4 μg/kg), indicating that it can be applied in routine analyses to provide a large amount of data related to the presence of drug residues in honey. The assay was validated according to 2002/657/EC criteria (3). In addition, it was comprehensively evaluated through application to 43 honey samples from diverse geographical regions of Romania, which were also characterized by an accredited LC/MS/MS assay (4). The combined approach allows an effective means of satisfying EU quality criteria specified for screening and confirmatory techniques (2003/181/EC & Regulation (EC) No. 470 /2009).

MATERIAL AND METHODS

Apparatus

A biosensor system, Randox Evidence Investigator™ analyzer (Randox Laboratories Ltd., Crumlin, Co. Antrim) was used for the simultaneous quantitative detection of multiple immunoassays from a single sample (5). The core technology is the biochip, a solid substrate containing discrete test regions (DTRs) of immobilized antibodies specific to different antimicrobials (6).

Reagents

Reagents, were supplied by Randox Laboratories Ltd. (Co. Antrim, Northern Ireland). The *Anti Microbial Array II (EV3524)* was used according to manufacturer's instructions to screen for 6 different types of antibiotics including ceftiofur (CEFT), florphenicol/thiamphenicol (TAF), quinolones (QNL), streptomycin/dihydrostreptomycin (STR), tetracyclines (TCN), tylosin/tilmicosin (TYL). The biochip array allows simultaneously screening of different families of compounds including the parent molecule and major metabolites.

Sample preparation

All honey samples were sourced from retail outlets in Romania. Honey samples determined by LC/MS/MS to be free of drug residues were used as negative controls. Several varieties of honey were examined in the survey. The sample was prepared using a rapid dilution method: weighing 1 g of honey, addition of 9 ml of diluted wash buffer (warmed to 37°C) to ≈1g of a honey sample, rolling for 10 minutes, and dilution with an equal amount of diluted wash buffer, filtration and application on the biochip. To take into account the dilution effect of preparation, the concentration reported were manually multiplied by 20.

Method validation

We evaluated the performance of the biochip method which has been initially validated a few years ago and is qualified to monitor CEFT, TAF, QNL, STR, TCN and TYL residues in honey. The abridged validation procedure applied here has the scope to demonstrate that the method works reliably in our laboratory, is fit for purpose and also follow the European De-

cision 657/2002/EC recommendation to calculate two statistical limits, CCα and CCβ, which allows to evaluate the critical concentrations above which the method reliably distinguish and quantify a substance taking into account the variability of the method and the statistical risk to take a wrong decision. For multi-class methods using biochemical tests the detection capability has to be determined for the representative analyte or the analyte with the lowest cross-reactivity (7).

The analytes chosen for our abridged validation were: ceftiofur, norfloxacin, ciprofloxacin, streptomycin, chlortetracycline, thiamphenicol and tylosin. For this particular biochip binding assay, calibrators are supplied with reagents, and the calibration curves are subsequently generated via the included software. However, given the complicated nature of honey as a sample matrix, all analyses were run alongside matrix-matched calibrants (a honey determined to be free of drug residues via LC/MS/MS, spiked at the appropriate levels). Linearity was then evaluated by spiking blank honey samples with different concentrations of antibiotics from 3 to 10 *μg/kg*. The calibration curves were generated with each of the analytes as standards in the competitive immunoassay. Once the response of these calibrators (measured in Relative Light Units, RLUs) had been determined, a calibration curve was constructed, applying the 4-parameter logistic model

Y= D + ((A-D) / (1+(x/C)^B))

where Y is the response generated, x is the concentration of the analyte, A is the response at zero analyte concentration, B is a slope factor, C represents the inflection point of the calibration curve, and D is the response at infinite analyte concentration.

Precision and accuracy of the method were studied spiking blank samples. Precision of the overall method was studied by performing repeatability (intraday precision) and inter-day precision experiments. Repeatability (intraday precision) was performed spiking blank honey at three concentration levels (10, 20 and 30 μg/kg), using twenty replicates for each concentration level in one day. To evaluate inter-day precision (reproducibility), the same concentration levels were studied, spiking blank honey during five consecutive days. Recovery was studied by analyzing blank samples that were fortified at three concentration levels (10, 20 and 30 μg/kg). Accuracy was estimated through recovery studies.

Decision limit and detection capability

The decision limit (CCα) is defined as the limit at and above which it can be concluded with an error probability of α that a sample is non-compliant. The capability of detection (CCβ) is defined as the smallest content of the substance that may be detected, identified and/or quantified in a sample with an error probability of β (5% for all substances with permitted or no permitted limit) (3, 7). The Regulatory Limit for unauthorized analytes is the Minimum Required Performance Limit (MRPL) or the Reference Point for Action (RPA). The Screening Target Concentration must be at or less than the MRPL (or RPA). For banned and unauthorized compounds where no MRPL has yet been established, CCβ should be as low as reasonably achievable. Methods for screening should be able to detect the analyte at the CCβ in 95% of the cases (7). For analized drug residues the RPA was stated at 20 μg/kg. This is the reason why we set the Desired Screening Target Concentration =

10 μg/kg. In order to determin the decision limit and detection capability, 20 blank matrix samples were selected. Replicates of these samples were spiked at the Screening Target Concentration = 10 μg/kg. The matrix blank samples and spiked samples were analysed. The decision limits (CCα, where α = 0.05) were calculated from the mean concentration of the 20 spiked samples at Desired Screening Target Concentration plus 1.64 times the corresponding standard deviations. The CCβ was obtained adding to CCα 1.64 times the same standard deviation.

The confirmatory method meet the requirements of Decision 2002/657/EC concerning the performance of method for the determination and confirmation of CEFT, TAF, QNL, STR, TCN and TYL residues in honey samples. Analysis were performed on an Agilent 1100 LC system (Agilent Technologies, USA) coupled to a 4000 Q TRAP mass spectrometer instrument (Applied Biosystems, USA). The following criteria were used for the confirmatory method: the signal-to-noise ratio (S/N) of the characteristic ions selected were > 3, the differentiation of the retention time of analyte and corresponding standard were within ±2.5%, the deviation of the relative abundance of the characteristic ions of the target matter and that of the characteristic ions of the corresponding standard were within ±20% to ±50%.

RESULTS AND DISCUSSION

Good linearity was obtained and determination coefficients were higher than 0.980 (tab. I). Satisfactory results were found, with recoveries higher than 70% for all the assayed compounds at the three concentration levels. Precision of the overall method was studied by performing repeatability (intraday precision) and interday precision experiments. Three concentration levels of the analytes were used and the intra-assay precision was determined from the results of twenty replicates of each level within the same run. The precision expressed as %CV and was always lower than 10% (table I).

The simultaneous immunoassays showed specificity for the target analytes. The limits of detection (LODs) ranged from 1 $\mu g/kg$ for TAF to 9 $\mu g/kg$ for TCN. Biochip array technology allowes simultaneous and selective multianalyte measurement of antimicrobials in honey at levels well below established Reference Point for Action (RPA) (tab. II). To validate the feasibility of the proposed method further, 43 honey samples of different types, from different geographical regions of Romania were purchased from local markets and analyzed. All 43 honey samples were tested and 9 were found positive for drug residues.

TABLE I

Analytical performance of Antimicrobial Array II

Assay	Calibration Range (µg/kg)	Determination coefficient R^2	LOD Honey (µg/kg)	Intra Assay Precision (n=20)
QNL	0 - 10	0.982	5	≤6.8 %
CEFT	0 - 7.5	0.986	3	≤6.8 %
TAF	0 - 5	0.998	1	≤6.8 %
STR	0 – 76	0.987	8	≤4.6 %
TYL	0 - 5	0.991	2	≤5.0 %
TCN	0 - 4.5	0.994	9	≤7.6 %

The presence of QNL, CEFT, TAF, STR, TYL and TCN were detected with the Antimicrobial Array II and the corresponding sample was confirmed by LC/MS/MS. The results showed that all samples which showed higher levels of drug residues in the examined honey were also positive in LC/MS/MS analyses (tab. III). Only one sample was positive for tylosin on Biochip Array and found to be negative with LC/MS/MS. For the tylosin in honey at low concentrations, Biochip method was able to determine precisely but it was not detected by LC/MS/MS. This result indicated that the sensitivity of this method is much higher than LC/MS/MS. No matrix interferences produced by endogenous compounds were observed for these analytes.

CONCLUSIONS

The method shows good linearity, sensitivity, specificity, precision (repeatability and intra-laboratory reproducibility), recovery, decision limits (CCα) and detection capabilities (CCβ) below 50% of established Reference Point for Action (RPA). The results of the validation process demonstrate that the method is suitable for application, as a quantitative screening method, in European Union statutory veterinary drug residue surveillance programmes. This biosensor method possesses the potential to be a fit-for-purpose screening technique in the arena of food safety technology. Following comparison with results obtained via the confirmatory technique (LC/MS/MS), the biochip array sensing technique has proven to be suitable for the rapid, simultaneous screening of the antibiotics in honey. This reduces the requirement for valuable LC/MS/MS time in the laboratory, as samples can be screened via this method, with suspected positives put forward to confirmatory testing. Use of microarray sensing techniques may hold much potential for the area of residue determination.

DETERMINATION OF METHANOL CONCENTRATION BY GC-MS IN A FATAL CASE POISONING (Abstract): Due to the consumption of alcoholic beverages with methanol content above the admitted limit, a woman from Bacău died at the Bacău County Hospital after 9 hours of hospitalization. **Materials and methods**: For the toxicological examination blood, liver, bile, stomach, intestine and kidney samples were analyzed in order to establish the concentration of methanol. Determination of methanol was carried out by gas chromatography coupled with mass spectrometry (GC-MS), analyzing the distillates obtained from blood and organs. We used an Agilent Technologies 7890 A gas chromatograph coupled to an Agilent Technologies 7683 C spectrometer. Helium was employed as mobile phase and a Phenomenex Zebron ZW-Plus polar column represented the stationary phase. Spectra acquisition mode: SIM, mass range followed: 15-500 atomic mass units, interpretation of the obtained results: Agilent Technologies ChemStation software. **Results**: After peak integration on the chromatograms, the following values of methanol concentration were obtained: 1.720 g ‰ in blood, 0.795 g ‰ in liver, 2.661 g‰ in bile, 2.287 g ‰ in stomach, 1.639 g ‰ in intestine and 1.590 g ‰ in kidney; the results have proved a large quantity of ingested methanol. They have also highlighted the absorption and distribution pattern of the methanol within the body. **Key words:** METHANOL, INTOXICATION, GC-MS.

Intoxicațiile metanolice se produc în mod frecvent prin confuzie cu alcoolul etilic, sau prin consumul de băuturi alcoolice ce au o concentrație metanolică peste limita admisă (1g/100 mL etanol anhidru) (1). Metanolul se metabolizează prin oxidare în ficat sub acțiunea alcool dehidrogenazei (AHD), în formaldehidă (lent) şi respectiv la acid formic (rapid) şi metil formiat (2, 3). Simptomele caracteristice intoxicațiilor metanolice sunt tulburările de vedere care apar la 10–15 ore de la ingestie şi acidoza metabolică (3, 4, 5). Intoxicația metanolică este, de cele mai multe ori, mascată de intoxicația etilică, acest fapt ducând la dificultăți de diagnostic (4, 5). În lucrarea de față se propune evidențierea distribuției şi absorbției metanolului în organism față de variația concentrației metanolice determinată prin cromatografie de gaze cuplată cu spectrometria de masă (GC-MS), în cazul unei morți prin intoxi-

caţie cu alcool metilic provenit din băuturi alcoolice.

PREZENTARE DE CAZ

O femeie de 32 de ani este internată în secţia Urgente a Spitalului Judeţean Bacău în data de 21.02.2010 cu diagnosticul "Coma gradul III, şoc toxic în observaţie" cu simptomatologia caracteristică. Examenele complementare respectiv, examenul biochimic al sângelui relevă: amilază -117 U/L, GGT–113 U/L, TGO–331 U/L şi TGP–147 U/L. Din datele de anchetă rezultă că femeia era o consumatoare cronică de băuturi alcoolice. Starea gravă a pacientei, cât şi lipsa de informaţii privind toxicul care a fost ingerat pe fondul consumului de băuturi alcoolice, a dus la o diagnosticare dificilă. Evoluţia a fost gravă cu deprimare respiratorie; pacienta moare prin stop cardio-respirator după 9 ore de la internare. Raportul de necropsie a cadavrului pune în evidenţă: edem cerebral difuz, plămâni cu numeroşi noduli fibroşi cu conţinut cazeos ce evidenţiau leziuni bacilare vechi. Stomacul prezenta mucoasa cu numeroase zone punctiforme hemoragice. Ficatul cu volum mărit, steatozic, pe secţiune cu structura hepatică ştearsă, consistenţă dură de culoare galben violaceu, pancreas cu structură glandulară păstrată, splina şi rinichii prezentând fenomene de stază. Examenul anatomo-patologic microscopic efectuat în cadrul departamentului de Anatomie patologică al I.M.L. Iaşi pune în evidenţă la nivelul creierului discrete focare de necroze neuronale acute şi uşoară vacuolizare a substanţei albe. La nivel pulmonar s-au evidenţiat multiple abcese cazeoase de etiologie tuberculoasă şi hemoragii cu edem alveolar acut. Ficat cu marcate şi difuze leziuni steatozice macro şi microvacuolare asociate cu discretă colestază intracitoplasmatică, rare microfocare necrotico-inflamatorii cu celule mononucleate şi mici arii de fibroză sinusoidală sau pericelulară. Fragmentele de organe au fost prelucrate pentru examenul microscopic prin coloraţia hematoxilină-eozină, Ziehl-Nilssen şi prin coloraţia PAS. Concentraţia alcoolului etilic s-a determinat în cadrul Laboratorului de Toxicologie al S.M.L. Bacău, prin metoda oficială de chimie analitică Cordebard, obţinându-se o valoare de 1,90 g‰.

MATERIAL ŞI METODĂ

Determinarea concentraţiei metanolice se efectuează prin cromatografie de gaze cuplată cu spectrometrie de masă din sânge şi fragmente de organe respectiv, ficat, bilă, stomac, intestin şi rinichi.

Reactivi şi aparatură

Reactivi:

- apă distilată,

- acid succinic 5% (MERCK ISO 9001 Reg. 303.1.0 Lot K38065981).

Aparatură:

- cromatograf de gaze tip Agilent Technologies 7890 A prevăzut cu injector automat tip Agilent Technologies 7683 B Series, cuplat cu un spectrometru de masă tip Agilent Technologies 5975C inert MSD. Faza mobilă, heliul, cu un debit de 1 mL/minut. În urma consultării bibliografiei de specialitate (6, 7, 8) s-a optat pentru folosirea ca fază staţionară a unei coloane cromatografice Zebron – Phenomenex, ZB-WAXplus (60 m x 0,25 mm; 0,25 µm).

- balanţa analitică (AND HR 200), sticlărie de laborator, instalaţie de distilare.

Pregătirea probelor

Probele de sânge şi fragmentele de organe au fost prelucrate prin distilarea unei cantităţi de 5 ml sânge sau 5 g ţesut cu un volum de 45 ml acid succinic 5%, culegându-se un volum de 25 mL distilat. Disti-

latul obținut s-a concentrat prin redistilare la un volum de 15 mL distilat.

Condițiile de lucru pentru GC-MS:

S-a injectat un volum de 0,1 µl distilat cu o rată de splitare 1/50. Programul de temperatură: temperatura injectorului 250°C, temperatura sursei MSD 230°C, temperatura cvadrupolului MSD 150°C; temperatura în compartimentul coloanei a fost menținută constantă timp de 20 minute la 50°C, apoi temperatura a crescut cu 10°C/min până la 250°C unde a fost menținută constantă încă 5 minute. Modul de achiziție a spectrelor: SIM, domeniul de masă urmărit: 15–500 unități atomice de masă, interpretarea rezultatelor obținute: Agilent Technologies ChemStation software. După înregistrarea spectrelor de masă, metanolul a fost identificat prin compararea timpilor de retenție ai picurilor corespunzătoare din cromatogramele distilatelor, respectiv cromatograma unei probe etalon ce conține metanol. Metoda a fost validată conform normelor de validare, într-un studiu anterior (8, 9, 10).

REZULTATE ŞI DISCUȚII

Din cromatogramele obținute pentru probele analizate, după integrarea picurilor corespunzătoare metanolului, valorile ariilor au fost utilizate pentru calcularea concentrației în metanol (µg/ml sânge, respectiv g țesut), valori redate în tabelul I. S-a calculat, de asemenea, concentrația metanolului în g la 1000 ml sânge sau g țesut, cât şi valoarea medie a concentrației metanolice.

TABELUL I

Valorile concentrației metanolice din sânge şi organe determinate prin GC/MS

Nr.	Distilat	Concentrația metanolului		
		µg/mL sânge, sau g țesut	mg/mL sânge, sau g țesut	g/1000 mL sânge/g țesut
1	Sânge	1720,342	1,720	1,720
2	Ficat	795,506	0,795	0,795
3	Bilă	2661,306	2,661	2,661
4	Stomac	2287,104	2,287	2,287
5	Intestin	1639,867	1,639	1,639
6	Rinichi	1590,389	1,590	1,590
Valoare medie				1,78

Datele experimentale obținute pun în evidentă valorile crescute ale concentrațiilor metanolice atât în sânge, cât şi în organele cercetate. Astfel, în sânge, concentrația metanolului este de 1,720 g‰, în ficat de 0,795 g ‰, în bilă de 2,661 g ‰, în stomac 2,287 g ‰, în intestin de 1,639 g ‰, iar în rinichi de 1,590 g ‰.

Din figura 1 se constată că valoarea cea mai mare a concentrației metanolice s-a determinat în bilă 2,661 g‰, iar valoarea cea mai scăzută în ficat, respectiv 0,795 g‰. Probele din intestin şi rinichi au valori apropiate şi anume 1,639 g‰ în intestin şi 1,590 g‰ în rinichi. Valoarea medie a concentrației metanolice obținute a fost de 1,78 g‰, valoare apropiată cu cea obținută din sânge, intestin şi rinichi.

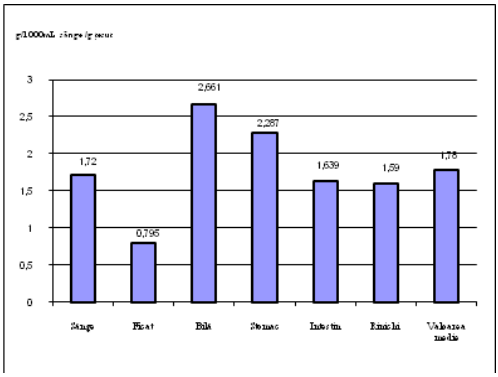

Fig. 1. Variaţia concentraţiei de metanol în sânge şi organe

Concentraţia metanolică în sânge, rinichi şi intestin reprezintă fiecare aproximativ 16% din concentraţia metanolică totală (valori apropiate de concentraţia medie). Ponderea cea mai mare se găseşte în bilă (24,88%), urmată de stomac (21,38%) (fig. 2).

DISCUŢII ŞI CONCLUZII

Faţă de datele din literatură, valorile concentraţiei metanolice obţinute în urma analizei probelor biologice se încadrează în intervalele valorice obţinute şi în alte cazuri de intoxicaţii letale cu metanol, respectiv intervalul 0,84–5,43g‰ metanol în sânge (11, 12).

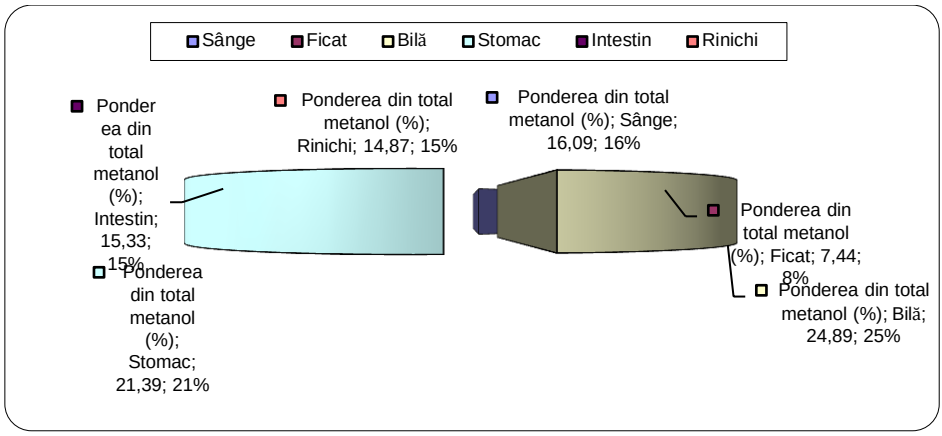

Fig. 2. Ponderea concentraţiei metanolice determinată în sânge şi organe

Datorită coeficientului lipo–hidrosolubilitatate, metanolul se distribuie în majoritatea organelor, cu precădere în organele cu concentraţii mari de apă (2, 3). În cazul de faţă, în bilă concentraţia metanolică este de trei ori mai mare faţă de concentraţia metanolică din ficat, unde s-a înregistrat cea mai scăzută valoare. Variaţia mare a valorilor concentraţiilor metanolice este explicată, în primul rând, de examenul anatomo-patologic. În cazul de faţă, steatoza hepatică cu degenerescenţă grasă diagnosticată la nivelul ficatului explică distribuţia neuniformă a toxicului. Valorile mari ale concentraţiei metanolice din stomac şi intestin pun în evidenţă faptul că metanolul a fost ingerat. Ştiind că rata metabolică a metanolului este de 25 mg/kg corp/h faţă de 175 mg/kg corp/h pentru alcool etilic, în cazul de faţă, decedata prezenta o alcoolemie de 1,90 g‰, rata de metabolizare a metanolului fiind extrem de scăzută, permiţând bioacumularea toxicului. Astfel, consumul excesiv de băuturi alcoolice coroborat cu tarele de sănătate (leziuni bacilare vechi, steatoză hepatică) şi, nu în ultimul rând, concen-

trația mult peste limită a metanolului din băuturile alcoolice consumate, au dus în cazul de față la deces. În urma studiilor întreprinse pe distilatele alcoolice naturale s-a constatat că 20% dintre acestea prezintă concentrații metanolice ce depășesc limitele admise (1g/100 ml etanol anhidru) (13), valoarea concentrației metanolice determinată în sânge și organe fiind fatală chiar și în cazul unui organism sănătos.

PHARMACOKINETIC MODELING OF GLIMEPIRIDE PLASMA CONCENTRATION IN HEALTHY SUBJECTS (Abstract): **Aim**: To determine the pharmacokinetics of glimepiride, a sulfonylurea antidiabetic agent, after single dose administration in healthy subjects. **Material and methods** Pharmacokinetic data for modeling were extracted from a single-center, randomized, single-dose, fasting state, two–way crossover bioequivalence study on 4 mg glimepiride in 24 healthy subjects. **Results**: Plasma concentrations of glimepiride were measured using a validated LC/MS/MS method. The pharmacokinetic parameters were calculated using non-compartmental analysis. Different pharmacokinetic models were tested to evaluate pharmacokinetics of glimepiride. The optimal model was chosen based on Akaike's Information Criteria. **Conclusion**: Compartmental analysis demonstrated that oral glimepiride tablets obey one compartment open model with rapid absorption following a first order kinetics and a short half-life. **Key words:** GLIMEPIRIDE, AKAIKE CRITERIA, COMPARTMENT MODEL, PHARMACOKINETICS.

Glimepiride is the first representative of the third class of sulfonylurea antidiabetic agents. Glimepiride is frequently used in monotherapy or in combination with other glucose lowering agents in non–insulin dependent diabetes mellitus treatment. Its primary mechanism of action is stimulation of release of insulin from pancreatic beta cells (1). In addition, extrapancreatic effects (such as increasing sensitivity of peripheral tissues to insulin) play an important role in antidiabetic effect of glimepiride (2).

The present study is designed to carry out the pharmacokinetic modeling of glimepiride in plasma after the administration of a single oral dose to healthy subjects.

MATERIAL AND METHODS

Study Protocol

The study was approved by an Independent Ethics Committee and National Medicine Agency. The single–center, single–dose, randomized, open label, fasting state, 2-way cross–over study was performed in

accordance with Declaration of Helsinki (3) and Guideline of Good Clinical Practice (4). A signed informed consent was obtained from all participants before the study.

Selection of Subjects

Twenty-four healthy Caucasian adult male and female subjects were selected for the study according to general requirements for bioequivalence studies (5). Subjects with no history of chronic or acute disorders were selected for the study. Volunteers unable to provide consent, with abnormal vital sign measurement or laboratory testing for hepatitis B or C or HIV, with abnormal findings on electrocardiogram (ECG) or with history of significant use of alcohol and drugs were excluded.

Subjects were considered eligible for enrollment in the study based on medical and medication histories, demographic and clinical data, ECG, physical examination, clinical laboratory testing, serum pregnancy test and urinary drug of abuse screen. No medication was allowed two weeks before and through the study.

Study design

The study design was a 2-way cross over study. All subjects were fasted for at least 10 h prior to drug administration. At time zero, an intravenous cannula was inserted into forearm vein and blank blood samples were collected. After baseline blood sampling, one 4 mg glimepiride tablet of either generic or brand formulation was administered according to the randomization schedule. Standard meals were allowed 4 h, 8 h and 12 h after drug administration.

Blood samples for the determination of glimepiride concentrations were collected in EDTA tubes pre-dose and at 0.33; 0.66; 1.0; 1.33; 1.66; 2.0; 2.33; 2.66; 3.0; 3.5; 4.0; 6.0; 8.0; 10.0; 12.0; 16.0 and 24.0 h post-administration. Plasma was separated after centrifugation and frozen and stored at -25°C until analysis.

PK Sample Analysis

Glimepiride plasma concentrations were determined using a validated LC/MS/MS method. Gliclazide was used as internal standard (6).

Pharmacokinetic and statistical analysis

The primary non-compartmental pharmacokinetic parameters were maximum plasma concentration (C_{max}), time to reach C_{max} (T_{max}), area under curve (AUC), mean residence time (MRT) and elimination rate constant (k_e). Both C_{max} and T_{max} were obtained from the plots of plasma concentration versus time. AUC was calculated using the trapezoidal method (log-linear). The k_e was obtained by linear regression of the terminal log linear phase of the concentration-time curve. The elimination half-life (t_{half}) was determined as $0.693/k_e$.

Both non-compartmental and compartmental pharmacokinetic data analyses were performed with the software program Kinetica® 5.0 (Thermo, Philadelphia) (7).

For compartmental analysis six mathematical compartmental models with first order absorption and elimination were used:

I. one-compartment, 0 order with lag time model
II. two-compartment, 0 order with lag time model
III. one-compartment, 1st order with lag time model
IV. one-compartment, 1st order without lag time model
V. two-compartment, 1st order with lag time model
VI. two-compartment, 1st order without lag time model.

The data were fit both to one compart-

ment and two compartment open models. The most appropriate model was chosen based on the Akaike information criteria (8).

The equations describing the compartments are:

$$C_p = C_1 e^{-k_d t} + C_2 e^{-ka t}$$

for one compartment model and

$$C_p = C_1 e^{-\alpha t} + C_2 e^{-\beta t} + C_3 e^{-ka t}$$

for two-compartment model, where C_p is the plasma concentration (ng/mL); k_d and β – disposition rate constants (h^{-1}); k_a is absorption rate constant (h^{-1}); α is distribution rate constant (h^{-1}); and C1, C2 and C3 are macrorate constants (9).

Discrimination between different pharmacokinetic models was performed for each study by minimizing the Akaike's information criterion test and Schwartz criteria and optimizing both the fitted versus the observed concentrations versus time and the weighted residuals versus the observed values relationship.

RESULTS

All data are presented as means ± standard deviation (SD) and CV%. In the study were enrolled 24 healthy Caucasian subjects with mean age 23.71 ± 3.96 years (range 19 - 32 years), mean height 1.75 ± 0.1 m (range 1.61 - 1.93 m), mean body weight 70.31 ± 12.33 kg (range 51 – 93 kg) and a mean BMI 22.56 ± 2.07 (range 19.00 – 25.0). All subjects completed the study and were included in analysis.

The mean plasma serum concentration vs. time curves after administration of the generic formulation of glimepiride is presented in fig. 1.

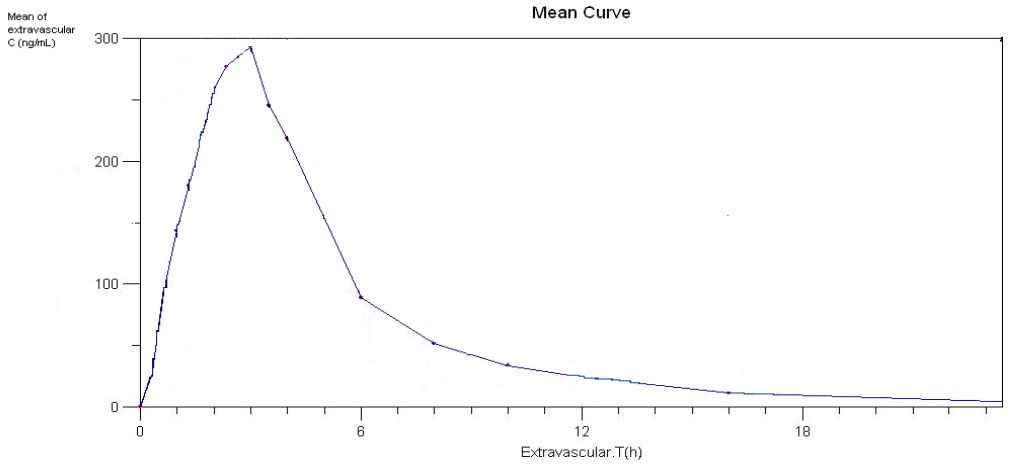

Fig. 1. Mean plasma concentration-time profile of glimepiride after a 4 mg single dose administration in healthy subjects (n = 24)

After single oral dose administration of 4 mg glimepiride, a C_{max} of 334.83 ng/ml was reached at 2.94 h. Elimination plasma half-life was 3.38 h. Pharmacokinetic parameters obtained by non-compartmental analysis are provided in table I.

The individual Akaike's values for the three analysed one-compartment models are presented in fig. 2. The main pharmacokinetic parameters calculated using this model are presented in table II.

TABLE I
Pharmacokinetic parameters of glimepiride by non-compartmental analysis

Pharmacokinetics parameter	Mean ± SD (CV%)
C_{max} (ng/ml)	334.83 ± 93.31 (27.87%)
T_{max} (hours)	2.94 ± 1.07 (36.34%)
AUC_{last} (ng*h/ml)	1449.69 ± 410.68 (28.33%)
T_{half} (hours)	3.38 ± 1.84 (54.46%)
MRT (hours)	5.56 ± 2.04 (36.75%)

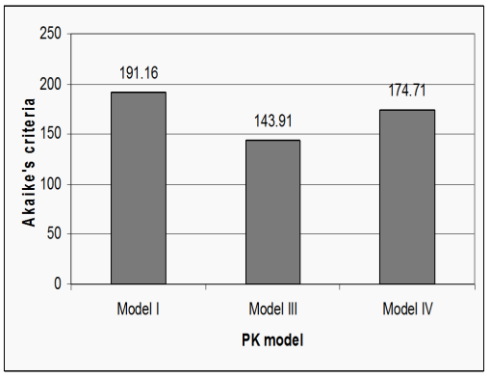

Fig. 2. Values of Akaike's index for one – compartment models

TABLE II
Pharmacokinetic parameters of glimepiride by compartmental analysis

Pharmacokinetic parameter	Mean ± SD (CV%)
$C_{maxcalc}$ (ng/ml)	290.99 ± 90.15 (30.98%)
$T_{maxcalc}$ (hours)	2.4 ± 0.59 (24.36%)
AUC (ng*h/ml)	1420.96 ± 401.96 (28.29%)
K_a (h^{-1})	0.74 ± 0.30 (41%)
Lag time	0.59 ± 0.42 (70.53%)
K_{el} (h^{-1})	0.48 ± 0.12 (25.25%)

DISCUSSION

For compartmental analysis, a comparison of Akaike's index criteria values demonstrated that a one-compartment was superior to a two-compartment model. In addition, the correlation matrix generated in the output report by Kinetica® accused a strong correlation between several parameters when a two-compartment model was attempted. This is an indication for over-parametrization and therefore, the one compartment model was chosen to explain the data. The discrimination between one-compartment models was based on the Akaike's index value. The model that fits better the data had to be characterized by a smaller Akaike's index. The analysis of the Akaike's index values revealed that the most appropriate model used to characterize pharmacokinetic of glimepiride was a one-compartment model with lag time.

Important data are available for characterization of glimepiride pharmacokinetics. Pre-authorization research and post–marketing experience of brand formulation Amaryl® (Aventis) reported information of glimepiride in various conditions: after single and multiple doses in healthy subjects, influence of age, co-medication, and disease state on plasma profile of glimepiride in both healthy individuals and patients (10). Some reports presented that glimepiride pharmacokinetics can be described by a two-compartmental model with a lag time (11). The investigators found a C_{max} of 191.5 ng/mL reached at approximately 4 h after administration of a single dose of 4 mg glimepiride in healthy subjects. After single dose administration of Amaryl® 4 mg tablets in 12 healthy subjects, C_{max} of glimepiride of 308 ± 69 ng/mL was reached in 2.1 ± 0.6 h. Almost similar results were found after single dose administration in patients with type 2 diabetes mellitus: C_{max} of 352 ± 222

ng/mL reached in 2.08 ± 0.51 h. In both healthy subjects and patients, glimepiride absorption was complete (100%) with significant absorption of glimepiride within 1 h after administration (11). The volume of distribution of glimepiride was 8.8 L (113 mL/kg) after intravenous administration. Elimination half-life in healthy subjects was 1.5 h. A significant increase of plasma elimination of glimepiride to 5.30 h was found in type 2 diabetes mellitus patients with altered renal function (12).

CONCLUSIONS

Both non-compartmental and compartmental pharmacokinetic analyses were performed for plasma concentration of a generic formulation of glimepiride after oral single-dose administration of 4 mg in healthy subjects.

In pharmacokinetic studies, it is necessary to select the correct model to allow an estimation of pharmacokinetic parameters with small bias and good precision to predict concentrations. This selection is based on analysis of Goodness of fits assessed with Akaike's Information Criteria, Schwartz Criteria, Residual Sum of Squares, standard deviation of the regression and determination coefficient. In the present study, Akaike's Information Criteria was the primary criteria for discrimination between pharmacokinetic models.

Overall, based on the detailed compartmental analysis, the results of this single dose study demonstrated that oral glimepiride 4 mg tablets obey one compartment model with lag time and with rapid absorption and a relatively short half-life. Further investigations will be performed on compartmental pharmacokinetic analysis to offer more flexible study application.

VALIDAREA UNEI METODE HPLC PENTRU DETERMINAREA OCHRATOXINEI A

Delia Bulea[1], A. F. Şpac[2], V. Dorneanu[3]
Universitatea de Medicină şi Farmacie ″Gr.T.Popa″ Iaşi
Facultatea de Farmacie
1. Disciplina Farmacodinamie
2. Disciplina Chimie-fizică
3. Disciplina Chimie analitică

VALIDATION OF A HPLC METHOD FOR OCHRATOXIN A DETERMINATION (Abstract): Ochratoxin A is a mycotoxin produced by various species of *Aspergillus* and *Penicillium*. Ochratoxin A has been detected in cereals and cereal products, coffee beans, beer, wine, spices, pig's kidney and cow's milk. For ochratoxin A, a HPLC method was developed and validated. Ochratoxin A was determined by RP-HPLC, using a liquid chromatograph type HP 1090 Series II, equiped with a fluorescence detector. The analysis was performed with a Phenomenex column, type Luna C18(2) 100A (150 x 4,6 mm; 5µm) with a mobile phase consisting of a mixture of acetonitrile/water/acid acetic (99/99/2), a flow of 0,7 mL/min. For detection, the wavelenght of excitation was 228 nm and wavelenght of emision was 423 nm. The calibration graph was linear in 6,25-50 ng/mL concentration range (r^2 = 0,9991). The detection limits was 1,6 ng/mL and the quantification limit was 4,9 ng/mL. The method precision (RSD = 2,4975 %) and the accuracy (recovery was 100,1 %) were studied. The HPLC method was applyed for ochratoxin A from food samples with good results. **Key words**: OCHRATOXIN A, VALIDATION, HPLC

Ochratoxina A este o micotoxină elaborată de specii de *Aspergillus* în zonele calde şi în cele tropicale şi de specii de *Penicillium* în zonele cu climă temperată (1). Ochratoxina A a fost detectată în cereale şi derivate, cafea, bere, vin, condimente şi în produse de origine animală - rinichi de porc şi lapte de vacă. Pentru determinarea ochratoxinei A a fost dezvoltată şi validată o metodă de analiză prin cromatografie de lichide de înaltă performanţă (HPLC), metodă utilizată la determinarea ochratoxinei A din probe de produse alimentare.

MATERIAL ŞI METODĂ

- Ochratoxina A from *Aspergillus ochraceus* (Sigma);
- Metanol Chromasolv ® min 99,9% (Sigma-Aldrich) ;
- Acetonitril R Chromasolv ® min 99,8% (Riedel-de Haën);
- Acid acetic glacial 100% (Sigma-Aldrich);
- Apă purificată (rezistivitate 18,2 MΩ);
- Balanţă analitică Adam;
- Filtre Millipore 45 µm;
- Cromatograf de lichide de înaltă performanţă de tipul HP 1090 Series II

prevăzut cu detector de fluorescenţă tip HP 1046 A;
- Coloană cromatografică Phenomenex Luna C18(2) 100A (150 x 4,6 mm, 5µm);
- Soluţie etalon stoc (40 µg/mL): 1 mg ochratoxină A se dizolvă în metanol şi se completează în balon cotat la 25 mL cu acelaşi solvent. Concentraţia soluţiei a fost verificată spectrofotometric (coeficientul molar de extincţie în metanol al ochratoxinei este de 6640 $cm^{-1}mol^{-1}$).
- Soluţie etalon de lucru: din soluţia stoc s-a preparat soluţia etalon de lucru de concentraţie 0,8 µg/mL în metanol. Din soluţia de lucru s-au preparat prin diluţie cu metanol soluţii cu concentraţii cuprinse între 6,25 ng/mL şi 800 ng/mL.

Mod de lucru

În literatura de specialitate există numeroase metode de determinare a ochratoxinei A prin metoda HPLC (2, 3, 4, 5). În cele ce urmează ne-am propus elaborarea unei metode simple şi rapide.

Determinările s-au realizat folosind ca faza staţionară coloana cromatografică Phenomenex Luna C18(2) (150 x 4,6 mm, 5µm), iar ca fază mobilă amestecul format din CH_3CN-H_2O-CH_3COOH (99:99:2, v/v/v), debitul fazei mobile fiind de 0,7 mL/min; temperatura în compartimentul coloanei a fost stabilită la 25°C. Detecţia s-a realizat în fluorescenţă cu λem = 228 nm şi λex = 423 nm. În vederea analizei, din soluţiile de lucru obţinute prin diluţie în metanol (6,25- 800 ng/mL) se injectează un volum de 20 µL. Timpul necesar unei analize este de aproximativ 16 min. ţinând cont că timpul de retenţie a ochratoxinei A este Tr = 13±5 % minute.

REZULTATE ŞI DISCUŢII

Pentru validarea metodei de analiză (6, 7, 8, 9) ne-am propus urmărirea următorilor parametri: selectivitatea, specificitatea metodei, determinarea liniarităţii, a limitei de detecţie, a limitei de cuantificare, a preciziei (precizia sistemului şi precizia metodei) şi a exactităţii.

Selectivitatea

Pentru determinarea selectivităţii metodei s-a procedat astfel: din analiza cromatogramelor soluţiilor de probă nu apar alte picuri la acelaşi timp retenţie, iar rezoluţia faţă de picurile adiacente este suficient de mare.

Specificitatea

Pentru determinarea specificităţii metodei a fost analizat solventul utilizat la prepararea soluţiilor standard şi a probelor. La timpul de retenţie corespunzător ochratoxinei A nu s-au obţinut picuri interferente.

Liniaritatea

Pentru determinarea liniarităţii au fost preparate soluţii de ochratoxină A în metanol în modul descris, pe intervalul 6,25 - 800 ng/mL. Pentru fiecare concentraţie s-au efectuat un număr de 3 determinări şi s-a calculat valoarea medie a ariei picului corespunzător ochratoxinei A. Datele experimentale obţinute sunt prezentate în tabelul I.

Valorile medii ale ariei picurilor au fost reprezentate grafic în funcţie de concentraţie şi s-a calculat ecuaţia dreptei de regresie (fig. 1).

Pe intervalul de concentraţie 6,25 - 800 ng/mL, variaţia ariei picului ochratoxinei A este liniară (r^2 = 0,9991, unde r^2 = coeficient de regăsire), dar, având în vedere faptul că intenţia este de a determina concentraţii cât mai mici de ochratoxină A din probe, am calculat ecuaţia curbei de calibrare pe intervalul 6,25 - 50 ng/ mL.

TABELUL I

Date experimentale pentru determinarea liniarității metodei de determinare a ochratoxinei A prin metoda HPLC

Conc (ng/mL)	Arie pic			
	I	II	III	Medie
6,25	10,10	10,40	10,30	10,27

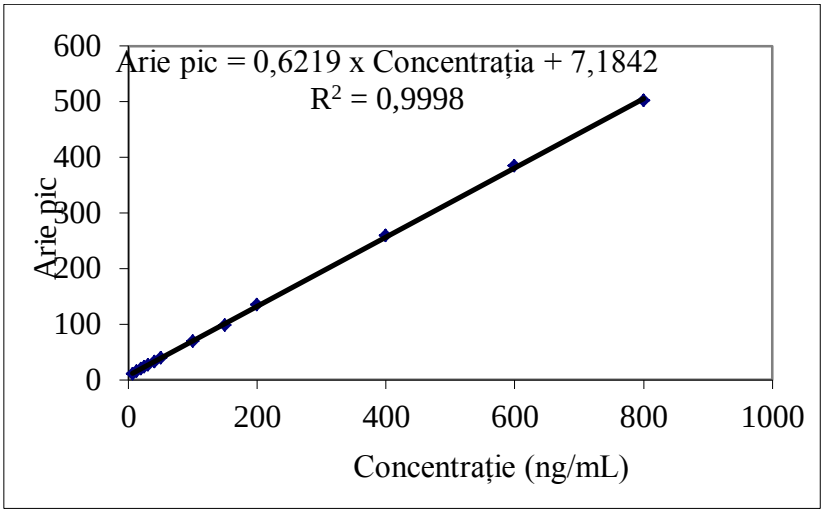

Fig. 1. Dreapta de regresie la determinarea ochratoxinei A prin metoda HPLC

Prin prelucrarea statistică se obține ecuația dreptei de calibrare Arie pic = 0,6339 x Concentrația + 6,7353 (r^2 = 0,9991), dar şi eroarea standard a dreptei de regresie (SE = 0,3123). Rezultatele obținute sunt prezentate în tabelul II.

TABELUL II

Evaluarea statistică a liniarității

Coeficient de regăsire (r^2)	0,9991
Eroare standard (SE)	0,3123
Intercept	6,7353
Panta	0,6339

Limita de detecţie şi limita de cuantificare

S-a calculat limita de detecţie (LD) şi limita de cuantificare(LQ) utilizând relaţiile:

$$LD = \frac{3,3 \times SE}{Panta} = \frac{3,3 \times 0,3123}{0,6339} = 1,6 ng/mL$$

$$LQ = \frac{10 \times SE}{Panta} = \frac{10 \times 0,3123}{0,6339} = 4,9 ng/mL$$

unde SE este eroarea standard a regresiei.

Precizia sistemului şi a metodei

În cadrul preciziei au fost studiate precizia sistemului pentru concentraţii de 25 ng/mL (pentru un număr de 10 determinări) şi precizia metodei pe un interval de 20 % faţă de concentraţia de interes (pentru un număr de 3 determinări la 3 nivele de concentraţie). Folosind ecuaţia dreptei de calibrare se calculează concentraţia pentru fiecare probă în parte şi procentul de regăsire. Datele experimentale obţinute sunt prezentate în tab. III şi tab. IV.

TABELUL III

Date experimentale referitoare la precizia sistemului

Nr. det.	Arie pic
1	22,71
2	23,22
3	22,90
4	22,84
5	22,83
6	22,73
7	22,74
8	23,19
9	23,30
10	22,84
Medie	**22,93**
SD	**0,2212**
RSD %	**0,9645**

După prelucrarea statistică a datelor obţinute se observă că deviaţia standard relativă (RSD) are valoarea 0,9645 %, faţă de maximul de 2 % prevăzut de normele europene, deci sistemul este precis (10).

TABELUL IV

Date experimentale referitoare la precizia metodei de determinare a ochratoxinei A prin metoda HPLC

Nr. det.	Concentraţie teoretică (ng / mL)	Arie	Concentraţie calculată (ng / mL)	Regăsire (%)
1	20	19,22	19,69	98,5
2		19,10	19,50	97,5
3		19,66	20,38	101,9
4	25	23,30	26,13	104,5
5		22,80	25,34	101,4
6		22,90	25,50	102,0
7	30	26,38	30,98	103,3
8		25,88	30,20	100,7
9		25,26	29,21	97,4
Date statistice			**Medie**	**100,8 %**
			SD	**2,5174**
			RSD	**2,4975 %**

Din datele experimentale obținute se observă că metoda este precisă, deviația standard relativă fiind RSD = 2,4975 %, față de maximul de 5 % prevăzut de normele europene (10).

Exactitatea metodei

Pentru determinarea exactității metodei pe un interval ± 20% față de concentrația de interes, au fost analizate 3 soluții de concentrații diferite, de 3 ori fiecare. Pentru fiecare analiză a fost determinată aria picului corespunzător ochratoxinei A şi s-a calculat concentrația folosind ecuația curbei de calibrare. S-a calculat regăsirea pentru fiecare probă în parte, valoarea medie şi intervalul de regăsire. Datele experimentale obținute sunt prezentate în tabelul V.

TABELUL V

Date experimentale referitoare la exactitatea metodei de determinare a ochratoxinei A prin metoda HPLC

Nr. det.	Concentrație teoretică (ng / mL)	Arie	Concentrație calculată (ng / mL)	Regăsire (%)
1	20	19,35	19,90	99,49
2		19,18	19,63	98,15
3		19,70	20,45	102,25
4	25	22,76	25,28	101,11
5		23,07	25,77	103,06
6		22,97	25,61	102,43
7	30	25,21	29,14	97,14
8		25,61	29,77	99,24
9		25,32	29,31	97,71
Date statistice			**Media**	**100,1 %**
			Min	**97,1 %**
			Max	**103,1 %**

Din datele experimentale obținute se observă că regăsirea medie este de 100,1 % pe intervalul 97,1-103,1 %, comparativ cu o limită de ± 10% prevăzută de normele europene, de unde rezultă că metoda este exactă (10).

CONCLUZII

A fost elaborată şi validată o metodă HPLC pentru detectarea ochratoxinei A. Astfel, determinările se efectuează pe o coloană Luna C18(2) 100A (150 x 4,6 mm, 5µm), cu o fază mobilă formată din CH_3CN-H_2O-CH_3COOH (99:99:2, v/v/v), debit 0,7 mL/min, cu detecție în fluorescență (λem = 228 nm, λex = 423 nm). Metoda este liniară pe domeniul de concentrații ales (6,25-50 ng/mL), ecuația dreptei de regresie fiind Arie pic = 0,6339 x Concentrația + 6,7353 (r^2 = 0,9991). Au fost calculate limitele de detecție (1,6 ng/mL) şi de cuantificare (4,9 ng/mL). S-a studiat precizia sistemului (RSD = 0,9645 %), precizia metodei (RSD = 2,4975 %) şi exactitatea (regăsirea medie = 100,1 %) pe intervalul 97,1 -103,1 %.

Metoda a fost aplicată cu rezultate bune pe probe de produse alimentare.

CONSIDERAŢII BIOMECANICE CU PRIVIRE LA FOLOSIREA SUBSTITUIENŢILOR OSOŞI ÎN TRATAMENTUL CHIRURGICAL AL OSTEOMIELITELOR CRONICE

Daniela Damir[1], Fl. Munteanu[2]
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină

1. Disciplina de Medicină legală, Etică şi deontologie, Bioetică
Facultatea de Bioinginerie Medicală
2. Disciplina de Tehnologie protetică şi Biotehnologie

BIOMECHANICAL CONSIDERATION REGARDING BONE SUBSTITUTES USE IN CHRONIC OSTHEOMIELITIS SURGICAL TREATMENT (Abstract): The main aim of this study is to present the use of bone substitutes in chronic ostheomielitis surgical treatment and its biomechanical influence. **Material and methods**: First step is three-dimensional reconstruction to one femur using CT sections; the second is the reconstruction of infected bone volume, synthesis of material properties, synthesis of loading forces, synthesis of boundary condition and, finally, finite element analysis. **Results**: The calculated Von Mises stress as a result of finite element analysis indicates that bone substitute implantation lead to a stress distribution in bone similar with a health femur. **Key words**: OSTHEOMIELITIS, BONE SUBSTITUTE, FINITE ELEMENT ANALYSIS

Osteomielita este inflamaţia osului şi a măduvei sale produsă prin infectarea pe calea sângelui (hematogenă) cu stafilococul auriu (o bacterie care populează şi suprafaţa tegumentară) sau alţi germeni (pneumococ, colibacil). Boala se poate prezenta sub o forma cronică sau acută.

Osteomielita cronică este o inflamaţie a osului care nu a fost precedată de fenomene de osteomielită acută. Clinic, semnul cel mai important îl constituie durerea, care este spontană şi intermitentă, calmându-se prin repaus. Aceasta are în general caracter nocturn.

În cazul osteomielitei cronice, tratamentul de elecţie va fi cel chirurgical, tratament ce vizează îndepartarea sechestrelor osoase ce întreţin infecţia.

Incizia se face la nivelul arătat de radiografie sau în locul unde există fistule ce drenează puroi din profunzime şi se îndepărtează sechestrul osos, care uneori poate fi de mărime apreciabilă, chiuretându-se cavitatea restantă.

Pentru o reintegrare socială rapidă a pacientului, este necesară umplerea cavităţii restante, rezultate în urma chiuretării, cu substitut osos care consolidează zona afectată, pe de o parte, iar pe de altă parte, în condiţiile în care substitutul osos este bioresorbabil, permite o regenerare facilă a ţesutului osos (1).

În această lucrare se va face o evaluare a stării de tensiuni care apar la nivelul unui femur afectat de osteomielită, a distribuţiei eforturilor unitare atunci când, în urma unei intervenţii chirurgicale, se îndepărtează ţesutului infectat şi în situaţia în care în cavitatea rezultată în urma chiuretării se introduce substitut osos.

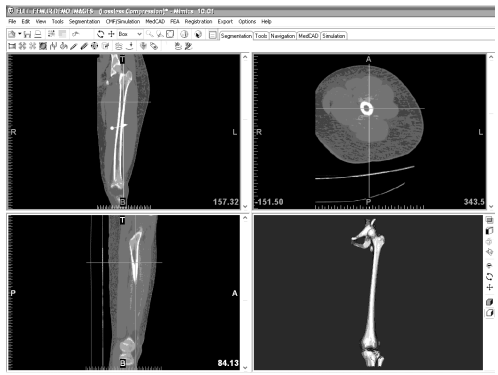

Fig. 1. Secţiunile CT şi rezultatul reconstrucţiei tridimensionale

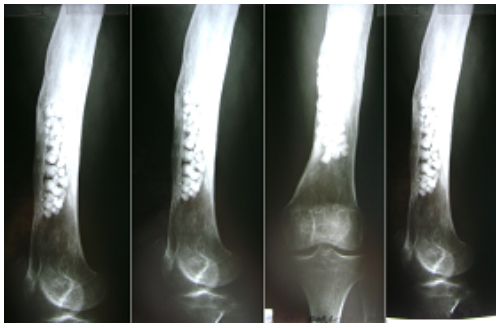

Fig. 3. Radiografii care stau la baza reconstrucţiei tridimensionale a zonei de os infecate

Comparaţia dintre cele două cazuri demonstrează un beneficiu biomecanic deosebit de important al substitutlui osos asupra osului ce se afla în proximitatea zonei infectate.

MATERIAL ŞI METODĂ

Modelarea virtuală ce va fi descrisă în cele ce urmează şi care este folosită frevent în evaluarea tensiunilor de la diferite nivele ale organismului uman, precum în: endoprotezare, radioterapie etc. (2,3), presupune parcurgerea următorilor paşi: sinteza obiectivelor analizei, sinteza geometrică a structurii, sinteza proprietăţilor de material, sinteza încărcărilor ce acţionează asupra structurii, sinteza reazemelor şi analiza propriuzisă (4,5,6).

a) ***Sinteza obiectivelor analizei.*** Analiza în element finit ce va fi făcută în continuare, urmăreşte evaluarea statică a tensiunilor, a deformaţiilor şi a deplasărilor apărute la nivelul femurului, în cele trei cazuri enunţate în introducere: femur normal, femur infectat şi femur tratat chirurgical cu cavitate restantă şi cavitate restantă umplută cu substitut osos.

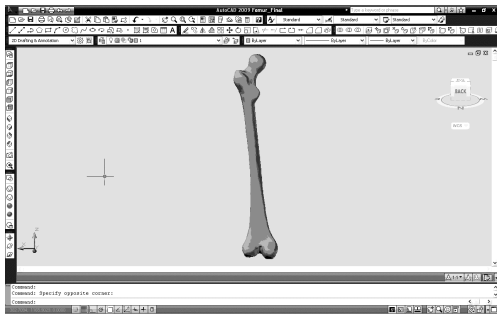

Fig. 2. Reprezentarea femurului în 3D în urma reconstrucţiei în AutoCAD 2009

b) ***Sinteza geometrică a structurii***. Pentru analiza curentă, care va fi făcută tridimensional (3D), se apelează la secţiunile CT ale coapsei, incluzând partea distală a pelvisului şi partea proximală a gambei (fig. 1). Secţiunile se inserează în soft-ul Mimics 10.01 care are posibilitatea de a reconstrui tridimensional, în urma aplicării unui set minim de comenzi, structurile osoase. Din modelul rezultat în Mimics, s-au extras secţiunile importante ale femurului, utilizând un alt soft dedicat reconstrucţiei 3D: AutoCAD 2009 (fig. 2).

În continuare se procedează la delimitarea zonei infectate din femur. În acest sens sunt utilizate un set de radiografii, care permit determinarea formei volumului infectat şi localizarea acestuia (fig. 3, 4).

Următorul pas constă în exportarea solidului din AutoCAD, reprezentat de femurul infectat, în soft-ul de analiză în elemnet finit Algor FEMPRO V. 23.1. În AutoCAD, se exportă şi se salvează fisierul cu extensia *.*sat. După deschiderea soft-ului Algor se deschide fisierul exportat anterior. Se dă comanda mesh, rezultatul fiind o discre-

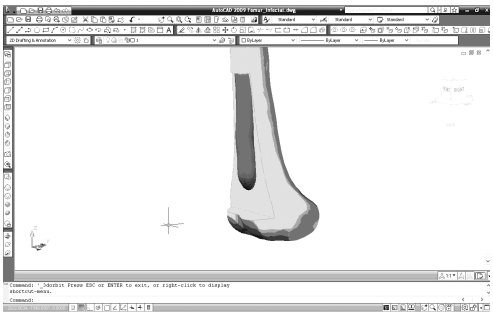

Fig. 4. Reprezentarea reconstrucţiei tridimensionale a zonei de os infectate

Fig. 5. Femurul infectat după operaţia de mesh-are

TABELUL I

Caracteristicile de material pentru fiecare componentă a structurii

Componentă	Modul de elasticitate [MPa]	Coeficientul lui Poisson	Densitate [kg/m^3]
Os	13.800	0,34	1100
Os infectat	150.000	0.4	1500
Substitut osos	55	0.45	1000

tizare a solidului reprezentat de femurul infectat. Rezultatul poate fi vizualizat în fig. 5.

c) Sinteza proprietăţilor de material

Pentru a se putea face analiza în element finit, trebuie definite, pe rând, pentru fiecare componentă a structurii : tipul de material, în care se vor defini, următoarele mărimi :

- densitatea materialului [kg/m^3] ;
- modulul de elasticitate [N/m^2] ;
- coeficientul lui Poisson ;
- modulul de elasticitate transversal [N/m^2] sau [Pa].

Se vor defini caracteristicile de material pentru os, ţesut osos infectat şi substitut osos (7,8,9) (tab. I).

d) Sinteza forţelor ce acţionează asupra structurii. Pe lângă muşchii care produc mişcările de flexie-extensie, abducţie--adducţie şi de rotaţie de la nivelul articulaţiei şoldului, mai sunt muşchii care au origine pe femur : biceps femural porţiunea scurtă şi cei trei muşchi vaşti, lateral, medial şi intermediar (fig. 1). În aplicarea forţelor asupra femurului s-a considerat forţa care acţionează asupra capului femural (care include forţele date de muşchii abductori, ischio-gambieri şi drept femural) şi forţele date de muşchii care au origine pe femur (fig. 6).

Valorile forţelor aplicate sunt (4) :

F_1 = 80N (muşchiul biceps femural porţiunea scurtă) ;

F_2 = 80N (muşchiul vast lateral) ;

F_3 = 70N (muşchiul vast intermediar) ;

F_4 = 90N (muşchiul vast medial) ;

F_5 = 2500N (forţa care acţionează asupra capului femural).

e) Sinteza reazemelor. Reazemele (locul de sprijin) se consideră a fi pe suprafaţa condililor femurali, şi reprezintă forţe de reacţiune ale forţelor musculare care acţionează pe femur (fig. 6).

REZULTATE

Odată parcurse toate etapele premergătoare amnalizei cu element finit, se dă comanda *analyse*.

Rezultatul distribuţiei de tensiuni este reprezentat şi poate fi vizualizat în fig. 7, unde sunt ilustrate stările de tensiuni pentru un femur normal (fig. 7.a), un femur infectat (fig. 7.b), femurul infectat după chiuretarea zonei infectate (fig. 7.c) şi situaţia în care cavitatea rezultată în urma chiuretării este plombată cu substitut osos (fig. 7.d). În fig. 7.e este reprezentat femurul mesh-at împreună cu volumul cavităţii chiuretate.

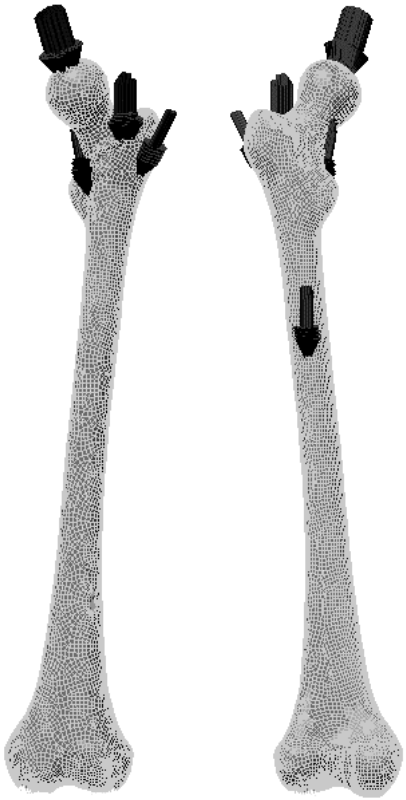

Fig. 6. Forţele date de muşchii vaşti, biceps femural (porţiunea scurtă) şi rezultanta de la nivelul capului femural

DISCUŢII

Se iau în discuţie cele patru cazuri analizate anterior.

În fig. 7, sunt ilustrate detaliile care cuprind zona în care se află infecţia osoasă şi mesh-ul femurului infectat, pentru a se putea face o corespondenţă corectă între distribuţia de tensiuni a fiecărui caz analizat şi poziţionarea volumului infectat (ulterior chiuretat sau a zonei cu substitut osos).

În comparaţie cu distribuţia de tensiuni de la nivelul femurului normal (fig. 7.a) se observă că pentru femurul infectat, în zona infecţiei, tensiunile au o valoare mai mică (fig. 7.b).

Femurul chiuretat prezintă o arie mare a tensiunii de valoare maximă (7kPa), în comparaţie cu cele ilustrate în figurile 7 a, b şi c.

Pentru femurul tratat cu substitut osos tensiunea are aceleaşi valori maxime ca şi pentru femurul normal (fig. 7.d), diferenţa fiind infomă.

Distribuţiile de tensiuni ilustrate în fig. 7, oferă informaţii asupra comportării biomecanice a osului. Pentru femurul cu infecţie osoasă, se observă că osul sănătos, adiacent infecţiei osoase, este mai puţin încărcat în comparaţie cu femurul normal.

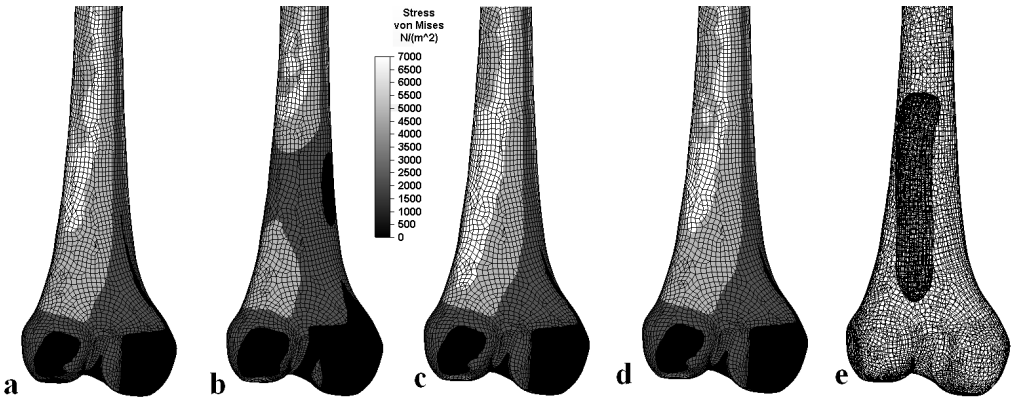

Fig. 7. a – distribuţia de tensiuni pentru femurul normal ; b – distribuţia de tensiuni pentru femurul cu infecţie osoasă ; c – distribuţia de tensiuni pentru femurul la care s-a îndepărtat infecţia osoasă prin chiuretaj ; d – distribuţia de tensiuni pentru femurul tratat cu substitut osos ; e – reprezentarea mesh-ată a femurului, cu evidenţierea zonei infectate.

Conform principiilor remodelării osoase şi ale mecanotransducţiei (10,11,12,13) într-un os mai puţin încărcat decât în condiţii fiziologice, normale, nu se mai realizează o reconstrucţie osoasă eficientă, ceea ce duce la o rarefiere osoasă, scăderea densităţii osului şi, implicit a rezistenţei la rupere (tensiunea de rupere a osului este direct proporţională cu densitatea osului la pătrat).

Acest lucru presupune posibilitatea apariţiei unei fracturi patologice, coroborată şi cu fragilitatea osului infectat (rigiditate mai mare, modul de elasticitate mai mare dar şi o elasticitate scăzută).

Astunci când, însă, distribuţia de tensiuni maxime se întinde pe o arie mai mare (fig. 7.c), osul este suprasolicitat, fiind posibilă o fractură înainte ca osul să se adapteze, în sensul densificării şi rigidizării.

În situaţia tratării zonei infectate cu substitut osos distribuţia de tensiuni ilustrază condiţiile unei regenerări ososase eficiente, fapt care, combinat cu proprietatea de resorbţie a substitutului osos, duce la refacerea ţesutului osos distrus prin infecţie (14,15).

Concluzia care se poate trage în urma analizei cu element finit este că, în cazul unei osteomielite cronice (semnul cel mai important il constituie durerea care este spontana si intermitenta, calmandu-se prin repaus), netratate, pot surveni complicaţii cu caracter biomecanic, una dintre ele fiind fractura.

CONCLUZII

În urma acestui studiu se pot trage următoarele concluzii :

1. Distribuţia de tensiuni pentru un femur cu infecţie osoasă :

a. Induce la nivelul osului adiacent infecţiei tensiuni mai mici decât în cazul osului sănătos ;

b. Tensiunea mai mică, presupune existenţa unor deformaţii mai mici ale osului adiacent infecţiei, o circulaţie ineficientă a fluidului prin canalicule şi, în consecinţă, o remodelare osoasă ineficientă, cu reducerea rezistenţei mecanice a osului ;

c. Încărcarea ineficientă a osului adiacent infecţiei osoase poate duce la fractura femurului în zona infectată, ştiut fiind faptul că solicitările complexe care apar la nivelul unui os lung duc la apariţia unor tensiuni mari, mai ales in zona diafizei osului ;

2. Starea de tensiuni pentru femurul chiuretat :

a. Induce la nivelul osului o tensiune întinsă ca arie depăşind, chiar proiecţia cavităţii pe suprafaţa osoasă ;

b. Tensiunea mare prezentă pe o arie întinsă, suprasolicită osul, fiind posibilă fracturarea.

3. Distribuţia de tensiuni pentru un femur tratat cu substitut osos :

a. Induce la nivelul osului adiacent substitutului tensiuni cu aceleaşi valori ca şi în cazul femurului normal, dar cu o arie de acţiune mai mare ;

b. Exitenţa unei tensiuni fiziologice, presupune o remodelare corectă a osului în zona considerată ;

c. Substitutul osos are în componenţă hidroxiapatită, ceea ce oferă o bază pentru reconstrucţie osoasă şi în regiunea care a fost infectată ;

4. Din cele enunţate anterior, se poate trage concluzia că tratamentul infecţiei osoase cu substitut osos este benefică, mai ales din punctul de vedere al comportării biomecanice a osului.

NOUTĂŢI

Boala osoasă Şi hipercalciura la copil

În literatura de specialitate există puţine studii privind masele osoase şi hipercalciuria idiopatică al copil (IH). Când a fost efectuată, măsurarea densităţii minerale osoase (BMD) a relevat o scădere semnificativă a Z-scorului pentru copiii cu IH, la nivelul apofizei spinoase spinei lombare şi mai puţin important la nivelul colului femural. Câteva investigaţii au descris natura mecanismelor implicate în pierderea de masă osoasă la aceşti copii. Unele studii desemnează creşterea reabsorbţiei osoase ca mecanism al pierderii osoase. Nu sunt raportări privind evaluarea prin biomarkeri specifici pentru formarea osoasă la copii cu IH. Totuşi, cei mai mulţi dintre copiii cu IH din aceste raportări au demonstrat o creştere staturală normală, ceea ce pare puţin probabilă în condiţiile unei alterări în formarea osoasă. Cauza creşterii rezorbţiei osoase, de asemenea, nu este pe deplin stabilită dar, factori genetici, indisciplina alimentară şi alterarea producţiei de citokine au fost propuşi drept contributori la descreşterea BMD observată la copiii cu IH. O fixare minerală optimă în os pe parcursul copilăriei şi al adolescenţei este importantă în atingerea unui vârf al masei osoase şi poate servi la prevenirea apariţiei osteoporozei la adult. Aceasta justifică eforturile de a înţelege mecanismele de pierderea a masei osoase la copiii cu IH (Zerwekh JE. Bone disease and hypercalciuria in children. *Pediatr Nephrol* 2010 ; 25 (3) : 395-401).

GRAPEFRUIT JUICE-DRUG INTERACTIONS: IMPORTANCE FOR PHARMACOTHERAPY (Abstract): In spite of known health benefits of grapefruit juice, its consumption in combination with drugs requires caution. The drugs most susceptible to pharmacokinetic interactions with clinical significance are those with narrow therapeutic index and low bioavailability due to important first-pass metabolism. Most vulnerable populations are elderly, cirrhotics, subjects with genetic polymorphisms and individuals taking other CYP3A4 inhibitors. The major drug classes that have been reported to present interactions with grapefruit juice are antiallergics, antibiotics, antimalaria drugs, anxiolytics, calcium channel blockers, HIV protease inhibitors, HMG-CoA reductase inhibitors; the degree of pharmacokinetic interaction varies among the compounds of the same class. **Key words**: GRAPEFRUIT, PHARMACOKINETIC INTERACTION, BIOAVAILABILITY

Grapefruit juice (GJ) is widely preferred among consumers as it is a good source of vitamin C, beta carotene, lycopene, folate, bioflavonoids, furanocoumarins, potassium and fibers (1).

Epidemiological facts, clinical trials and animal studies provide strong evidence that GJ reduces risk of cardiovascular diseases (2) and some types of cancer (3,4,5,6,7).

In spite of all these health benefits, mixing GJ with drugs needs special caution. GJ is known to increase the oral bioavailability of many CYP3A4 substrates by inhibiting intestinal phase metabolism and by down regulating CYP3A4 in the small intestine (8).

However, recent data indicate that other mechanisms than inhibition of CYP3A4 are involved in GJ - induced pharmacokinetic interactions. GJ also inhibits some drug transporters like P-glycoprotein (P-gp) and Organic Anion Transporting Polypeptides (OATP) (9). This may help to explain the inconsistent data regarding GJ - drugs interactions and the large variability of the aria under curve (AUC) among patients.

The degree of the interaction with an enzyme inhibitor can be assessed based on midazolam effect. The pharmacokinetic interactions are classified as follows:

- weak - less than two fold increase of AUC of midazolam;
- moderate - two to five fold increase of AUC of midazolam;
- strong - more than five fold increase of AUC of midazolam (10).

REPORTS ON GRAPEFRUIT JUICE-DRUG INTERACTIONS

The GJ - **calcium channel blocker** interaction has been known since 1989 (11).

The co-administration of GJ with some **dihydropyridine** calcium channel antagonists like felodipine, nifedipine (12), nicardipine (13), nimodipine (14), nisoldipine (15) and nitrendipine (16) leads to increased AUC ranged from 1.5-fold to 4.0-fold. Especially among the elderly, the increased bioavailability is associated with enhanced reduction of both systolic and diastolic blood pressure and increased frequency of vasodilatation--related side events. The interaction between amlodipine and GJ doesn't present clinical significance because amlodipine has high (80%) oral bioavailability (17).

In the **phenylalkylamines** calcium channel antagonists group, verapamil exhibits a weak interaction with GF and a high inter-subject variability. In a study realized by Fuhr, prolongation of PR interval above 350 ms occurred in two of the 24 individuals in the group receiving GJ (18).

In the **benzothiazepine** calcium channel antagonists group, diltiazem has been found to have an increased bioavailability when co-administrated with GJ but these results need further investigation (19).

Carvedilol is a racemic mixture in which nonselective **β-adrenoreceptor blocking** activity is present in the S(-) enantiomer and **α1-adrenergic blocking** activity is present in both R(+) and S(-) enantiomers at equal potency. Carvedilol has an absolute bioavailability of approximately 25%-35% due to a significant stereoselective first-pass metabolism by CYP2D6, CYP2C9 and CYP3A4 enzymes. Following oral administration in healthy subjects, plasma levels of R(+) -enantiomer is 2 to 3 times higher than S(-) -enantiomer. Subjects with genetic polymorphism (poor metabolizers) present almost 3-fold higher plasma concentrations of R(+) -carvedilol and 1.25 - fold higher plasma levels of S(-)-carvedilol compared to extensive metabolizers. Drinking GJ while taking carvedilol may increase side effects of carvedilol and modify the therapeutic activity. In these circumstances, until new data is available, patients with heart failure receiving carvedilol should avoid GJ intake (8).

Losartan - **angiotensin II receptor (type AT1) antagonist** - is an orally active drug that undergoes substantial first - pass metabolism by CYP2C9 and CYP3A4 enzymes. It is converted, mainly to an active carboxylic acid metabolite (E3174) which is 10-40 times more potent than the parent drug. In healthy volunteers, GJ increases significantly the time to losartan appearance in serum and decreases significantly AUC of the E3174 metabolite suggesting loss of drug efficacy (20).

Amiodarone is an **antiarrhythmic** drug which can cause QTc interval prolongation and severe cardiac ventricular arrhythmia - torsade de pointes. Amiodarone is metabolized by CYP3A4 to N-desethylamiodarone - a metabolite with more potent anti-arrhythmic properties. GJ increases the amiodarone plasma concentrations and inhibits almost completely the production of the active metabolite leading to fewer side effects but also to diminished therapeutic action (21).

Even it has good oral bioavailability (which varies widely 45-100% between patients), the antiarrythmic quinidine should not be associated with GJ without cautious risk and benefit assessment. Careful monitoring of this drug is important due to its narrow therapeutic index and similarity in patient response to sub-therapeutic and toxic amounts of the drug.

HMG-CoA reductase inhibitors - a class of lipid-lowering agents - are associated with the increase the risk of myopathy and rhabdomyolysis, particularly in patients taking higher doses.

Lovastatin, simvastatin, and atorvastatin are highly prone to interactions due to their reduced oral bioavailability as a result of

presystemic metabolism by CYP3A4 (22). Two days of pretreatment with 200 ml double strength GJ three times a day (high dose of GJ) increases AUC for lovastatin and lovastatin acid 15- and respectively 5-fold, without influencing the half-life.

Similar results was obtained by Lilja et al. (23) who showed that GJ increased AUC of simvastatin 16-fold and the Cmax of simvastatin acid about 7-fold. When simvastatin is taken 24 hours after ingestion of high dose GJ, the effect on the AUC of simvastatin is only about 10% of the effect observed during concomitant intake of GJ and simvastatin.

In contrast, pretreatment with 200 ml double strength grapefruit juice three times a day for 2 days increased AUC of atorvastatin only 2.5-fold (22). The half-life of atorvastatin increased from 7.8 hours to 13.3 hours (25). Analogous study reported that GJ didn't change AUC of pravastatin.

As fluvastatin has a good oral bioavailability and is predominantly metabolized by CYP2C9, its use together with GJ is not a matter of concern. In patients who consume GJ together with HMG-CoA reductase inhibitors, potential alternative agents are pravastatin, fluvastatin, or rosuvastatin (8).

At therapeutic drug concentration, sildenafil selectively **inhibits phosphodiesterase PDE5** to increase intracellular cGMP concentration in *corpus cavernosa*. At higher drug concentration, the selectivity of sildenafil for PDE5 is lost and other forms of PDE are inhibited, resulting in a generalized increase in intracellular cGMP and systemic vasodilatation. The clearance of sildenafil is reduced in healthy elderly volunteers (over 65 years) and the free plasma concentrations are approximately 40% greater than in healthy younger volunteers (18-45 years). After GJ consumption, the magnitude of sildenafil AUC increase is variable ranging from 0.8 to 2.6. As AUC can increase even more depending on brands, batches and the volume of GJ intake it is recommended that the combination of sildenafil and GJ should be avoided (26). Also, interaction with tadalafil or vardenafil may cause serious systemic vasodilatation especially when combined with a nitrate (8).

Five of twelve drug withdrawals from the market from 1997 and 2002 were caused by pharmacokinetic interactions. **H1-receptor antagonists** astemizol and terfenadine and the gastrointestinal prokinetic agent, cisapride are CYP3A4 substrates; increased concentrations of these drugs due to pharmacokinetic interactions were associated with QT prolongation, torsades de pointes and other ventricular arrhythmia. Severe side--effects were also reported for calcium channel blockers mibefradil and HMG-CoA reductase inhibitor cerivastatin which are also CYP3A4 substrates (27). Ebastine and loratadine, other H1-receptor antagonists, which undergo important first-pass metabolism by CYP3A4 may also present higher concentrations levels after GJ administration. Although the co-administration of loratadine with CYP3A4 inhibitors such as erythromycin, ketoconazole, clarithromycin and cimetidine is associated with increases the loratadine's levels, the prolongation in the QTc interval doesn't occur. The arrhythmogenic potential of the ebastine is higher as it is chemically related to terfenadine.

Special care should be taken into consideration also for psychiatric patients who use drugs with narrow therapeutic index such as tricyclic **antidepressants** (clomipramine) or **anticonvulsivants** like carbamazepine (28). According to Lee et al. (29), GJ increases bioavailability of sertraline with 50%. Regarding **anxiolytics**, in healthy volunteers, midazolam AUC increased with 52% when given with GJ and triazolam AUC with 96% as compared to control group (30, 31, 32). The administration of GJ needs special caution in cirrhotic patients, elderly individuals or subjects taking other CYP3A4

inhibitors. In these patients GJ increased the AUC of midazolam by 106% and decreases the ratio of the AUCs alpha-hydroxymidazolam (metabolite) /midazolam by 85% (33) which may result in excessive sedation and other side-effects. Furthermore, GJ raise dramatically the AUC of non-benzodiazepine anxyolitic buspirone by 9.2 fold (34).

Interesting results are provided by an experimental study which shows that GJ significantly increases the blood concentration of **morphine** in morphine-tolerant rats (35). Also, a clinical trial showed that GJ augments significantly the bioavailability of dextromethorphan with up to three days persistence of the juice impact (36).

Even if GJ almost doubles the AUC for macrolides like clarithromycin the clinical significance of this pharmacokinetic interaction is not relevant (37, 38).

The inhibitory activity of GJ does not always have negative impact as it can also be used to maintain the drug effectiveness. Artemether is a **antimalarial drug** which undergoes high presystemic metabolism by CYP3A4 and presents a high relapse rate during monotherapy (due to autoinduction). GJ increases the oral bioavailability of artemether (39), achieves complete protection of the host from damage induced by schistosomal infection (40) but still cannot prevent the time-dependent reduction in bioavailability.

Halofantrine, another antimalarial drug, presents an oral bioavailability of 10% and is metabolized by CYP3A4 to the less cardiotoxic metabolite, N-debutylhalofantrine. Charbit et al. showed that GJ administration increased halofantrine AUC by 2.8-fold and decreased N-debutyl-halofantrine AUC by 2.4-fold. As GJ prolonged QTc with approximately 82%, this beverage should be contraindicated during administration of halofantrine (41).

Ten years ago a report drew attention to potential fatal interaction between GJ and other drug with narrow therapeutic index – colchicine (an agent used for **gout** treatment) (42). In addition, in Caco-2 cells GJ reduced ratio of basal-to-apical transport to apical-to-basal transport suggesting that, *in vivo,* the bioavailability of this drug might be increased by GJ consumption (43).

Another class of drugs which presents clinically relevant pharmacokinetic interactions with GJ is the **inhibitors of HIV protease** - ritonavir, indinavir, saquinavir, nelfinavir (44). The bioavailability of saquinavir increases twice after GJ consumption (45).

The co-administation of **immunosuppressive** agent cyclosporine (frequently used in the prophylaxis of organ rejection) with GJ increases AUC by 186% as compared with water (46, 47, 48). Also concentration of tacrolimus should be closely monitored when combined with GJ (49).

On the contrary, GJ decreased AUC of the **antineoplasic** agent etoposide with approximately one quarter when administered concomitantly (50). Studies realized on Caco-2 cells indicate that the ratio of basal-to-apical transport to apical-to-basal transport of [3H] vinblastine was reduced by extracts of GJ (51, 52). Further research is needed to underline the clinical significance of this interaction.

Interaction between **hormones** like ethinyl--estradiol (53) or methylprednisolone and GJ can be considered weak and seem to be unlikely to be clinically relevant. It has to be mentioned that a decrease in morning cortisol plasma concentrations has been observed after administration of methylprednisolone with GJ (54,55). Recent data show that regular intake of GJ presents an important impact on the bioavailability of budesonide nearly doubling it (56).

Our data show that, in healthy volunteers, the association of non-steroidal anti-inflammatory drugs like celecoxib or diclofenac with GJ presents a large inter-subject variability. In one subject taking celecoxib, Cmax increased by 3.17 fold and AUCtotal by

1.83 fold. Also, in one case, GJ administration increased Cmax of diclofenac by 3.27 fold and decreased elimination half-life by 2.81 fold.

CONCLUSION

When there is a concern for drug toxicity related to increased plasma drug concentration it is recommended that GJ consumption should best be avoided entirely during pharmacotherapy.

NOUTĂŢI

COMPUŞI CU ACŢIUNE ANTI-OSTEOPOROTICĂ DIN PLANTE MEDICINALE DIN INDIA

Acest studiu a avut drept scop evaluarea *in vitro* a efectelor osteogenice ale unor plante utilizate în medicina tradiţională indiană în tratamentul fracturilor osoase : *Allophylus serratus* (Roxb) Kurtz (*Sapindaceae*), *Cissus quadrangularis* (*Vitaceae*), *Vitex negundo* (Linn.) (*Verbenaceae*). Din aceste plante au fost izolaţi 14 compuşi. Posibilele efecte osteogenice ale acestor compuşi au fost evaluate *in vitro* pe culturi primare de osteoblaste. 5 dintre compuşii testaţi (rutozida, 6'-O-trans-cinamoil catalpolul, agnuzida, negundozida, luteolina) au determinat o creştere a ratei de diferenţiere a osteoclastelor şi a mineralizării. Rezultatele obţinute justifică utilizarea acestor specii în medicina tradiţională indiană în tratamentul fracturilor osoase (Kumar M, Rawat P, Dixit P et al. Anti-osteoporotic constituents from Indian medicinal plants. *Phytomedicine* 2010 ; 17 : 993-999).

CHEMICAL COMPOSITION OF THE ESSENTIAL OIL OF *SALVIA OFFICINALIS* L. FROM ROMANIA (Abstract): The quantitative and qualitative analysis of essential oils obtained from *Salvia officinalis* L. (*Lamiaceae*) cultivated in Romania is reported in this paper. **Material and methods**: The essential oils were obtained from fresh and dried material harvested from plants cultivated in Cluj (Romania) and from 2 commercial samples, by hydrodistillation. The essential oils were analysed by GS-MS. **Results**: 12 compounds were found in each oil, 9 of them being common in all samples. The α-thujone was the major compound in all analysed oils (31.23-52.86%), followed by camphor and viridiflorol. Chemically, the oxygenated monoterpenes are present in highest quantity (49.78-79.2%). **Conclusions**: The monoterpenoid ketones' presence (á-thujone, â-thujone, camphor) in high amounts in the essential oils of Romanian sage may develop toxicity for these products and may limit their medicinal use. **Key words**: ESSENTIAL OIL, *SALVIA OFFICINALIS* L., OXYGENATED MONOTERPENES

PANTOTHENIC ACID – APPLICATIONS, SYNTHESIS AND BIOSYNTHESIS

PANTOTHENIC ACID – APPLICATIONS, SYNTHESIS AND BIOSYNTHESIS (Abstract): Pantothenic acid, also known as vitamin B5 or anti-stress vitamin, is a water-soluble vitamin with various applications in pharmaceutical industry (ointments, solutions for treating lesions and irritation of the skin or mucous membranes, multivitamin supplements - tablets, capsules, effervescent tablets, chewable tablets, syrups), food industry (dietetic foods, baby products, cereals, juices), cosmetics (component of shampoos, hair masks, balms, creams and sunscreen lotions, baby products), and widely used as feed additive. Currently, pantothenic acid is produced by chemical synthesis using pantolactone and the calcium salt of β - alanine, but it can also be obtained by fermentation processes which involve different bacterial species, as well as a number of yeasts. Lately, the demand for pantothenic acid for cosmetic and dermatocosmetic industry registered a significant increase. In this context, obtaining pantothenic acid by fermentation has become a promising method because it does not have a negative environmental impact, it uses renewable resources and cheap raw materials, and global consumer demand for organic products is increasingly higher. **Keywords:** PANTOTHENIC ACID, APPLICATIONS, PRODUCTION.

Pantothenic acid is an organic acid having the formula $C_9H_{17}O_5N$ (fig. 1). From the chemical point of view, pantothenic acid is the amide of pantoic acid with β-alanine.

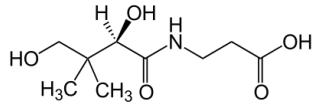

Fig. 1. The chemical structure of pantothenic acid

Pantothenic acid was discovered in 1931 by RJ Williams. In 1933, vitamin B5 was isolated from yeast, and a few years later, RJ Williams successfully establish the chemical structure and extract the compound from liver (1). The main role of pantothenic acid in cells is the synthesis of coenzyme A (CoA). Coenzyme A acts as an acyl group carrier to form acetyl-CoA and other related compounds. CoA is very rich in energy and enzymatically reacts on two distinct paths: an anabolic pathway, where acetyl-CoA is the starting point in many biosynthetic processes (in the biosynthesis of fatty acids, cholesterol, and acetylcholine) and a cata-

bolic pathway that continues with the tricarboxylic acid cycle (Krebs cycle) and ends with the respiratory chain. Pantothenic acid in the form of CoA is also involved in signal transduction and enzyme activation and deactivation (2, 3) (fig. 1).

PANTOTHENIC ACID APPLICATIONS

Regarding the human body, this compound is involved in the health of the digestive, nervous, circulatory, and skeletal systems, skin and hair, as well as in the synthesis of hormones (insulin, adrenaline) (4). Combs G.F. Jr. (5) consider that it also plays an important role in increasing the immunity of human body. Panthenol, another form of vitamin B5, is used in hair care products, considering that it interferes in maintaining a healthy aspect of it, acting as a humectant to facilitate the increase of water content and elasticity. At the same time, it protects the skin from harmful effect of radiation, moisturizes the skin, mucous membranes and cornea. In addition, the administration of high doses of pantethine (500-1200 mg/day) to subjects suffering from dyslipidemia (blood lipid pathological change) and diabetes, it was found that it is effective in reducing the level of cholesterol and triglycerides in the blood, treating fatty liver and related diseases. Some studies suggest that vitamin B5 supplements may speed the healing of superficial wounds, especially after surgery. This quality is important in case of burns, when a significant proportion of micronutrients are lost, phenomenon that increases the risk of infection and slows healing (4).

Pantothenic acid is found in all living cells (pantos = everywhere) and is widely found in foods, so deficiency of this substance is generally rare encountered. The richest sources of vitamin B5 are: yeast, royal jelly, cereals, vegetables, egg yolk, liver and kidney, beef, soy, nuts/peanuts, walnuts, mushrooms (4, 6) (tab. I).

TABLE I

Sources of vitamin B5 and content

Sources	Content, mg/100g	Sources	Content, mg/100g
Meat		**Vegetables**	
beef	0.3-2	avocado	1.1
pork	0.4-3.1	broccoli	1.2
young cattle kidney	3.9	cabbage	0.1-1.4
chicken liver	9.7	carrots	0.27
young cattle liver	8	cauliflower	1
pork liver	7	lentil	1.4
Cereals		potatoes	0.3
wheat flour	0.21	soybeans	1.7
wheat bran	2.1	tomatoes	0.3
whole wheat	1.2	**Nuts**	
soy flour	1.4	Cashew	1.3
oatmeal	1.1	Peanuts	2.8
whole rice	1.1	walnuts	0.8
Fruits		**Others**	
apples	0.1	eggs	2.9
strawberry	0.3	milk	0.2
oranges	0.25	mushrooms	2.1
blackcurrants	0.4	yeast	5.3-11

Recommended daily doses of vitamin B5 (tab. II) depend on, besides age and sex, on daily caloric consumption and physiological state of the body (7). Vitamin B5 deficiency symptoms include: fatigue, insomnia, depression, irritability, listlessness, nausea and vomiting, abdominal cramps, muscle weakness, burning sensation in the extremities. In hypovitaminosis, at molecular level, changes occur in the biosynthesis of corticosteroids and cholesterol, inhibition of the oxidative decarboxylation pathway of pyruvate and metabolism of fatty acids, as well as in the antibody biosynthesis process.

TABLE II

Recommended daily doses of pantothenic acid

Pediatrics	Recommended daily intake, mg	Adults	Recommended daily intake, mg
0 - 6 months	1.7	19 years and older	5
6 months - 1 year	1.8	pregnant women	6
1 - 3 years	2	breastfeeding women	7
4 - 8 years	3		
9 - 13 years	4		
14 - 18 years	5		

THE CHEMICAL SYNTHESIS OF PANTOTHENIC ACID

The production of calcium pantothenate, pantothenic acid commercial form, is performed chemically, by heating pantolactone with β-alanine (calcium or sodium salt) in methanol or ethanol (fig. 2).

Racemic pantolactone was obtained in a yield of about 90% from isobutyraldehyde, formaldehyde and hydrogen cyanide, without the need for separation of the intermediate products. Saponification of the second intermediate with a strong acid causes the formation of pantolactone in the reaction media, which can be separated by extraction and/or distillation (6).

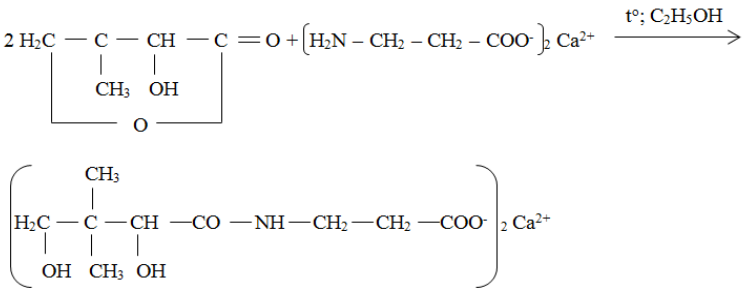

Fig. 2. Calcium pantothenate production by chemical synthesis

For obtaining biologically active enantiomer, R (D)-pantolactone, several methods were developed (6):

1. fractional crystallization of diastereoisomeric salts or amides of pantothenic acid with alkaloids or synthetic chiral amines;

2. the cleavage of the racemic mixture and recycling of S-enantiomer - can be made either by heating with an aqueous solution of NaOH at 150°C for a few hours, until the obtaining of sodium pantoat, or by treatment with very alkaline amines or alkoxides;

3. stereo selective hydrogenation of 2-oxolactone (obtained either by oxidation of 2-aminolactone or pantolactone, or by acid treatment with dimethylpiruvic formaldehyde).

The industrial synthesis of β-alanine can be performed by two methods (6):

a) the addition of ammonia to acrylonitrile, followed by basic hydrolysis of the nitrile with formation of the sodium salt of β-alanine; after sulfuric acid treatment, evaporation and extraction of the residue with methanol, crystalline β-alanine is obtained;

b) ammonia addition to acrylic acid, in which case the sodium salt formation is avoids.

An important problem associated with industrial obtain of calcium pantothenate, apart from the use of toxic chemical reagents - hydrocyanic acid, is the laborious and expensive step of optical resolution of racemic pantolactone. Thus, numerous studies have concentrated on the development of more efficient methods for the preparation of D-pantolactone, the biologically active isomer (8, 9).

Therefore, a more economical alternative to conventional resolution, that uses a quite expensive synthetic alkaloid series, is the biotransformation of racemic pantolactone using a fungal enzyme, lactonohydrolaze, as biocatalyst. The stereospecific hydrolysis of D-lactone is catalysed by this enzyme. Because D-pantolactone is one of the preferred substrates, lactonohydrolaze rapidly converts it in D-pantoic acid, while the L-enantiomer of the racemic mixture remains unchanged and will be racemized and recycled for a new cycle of optical resolution (8, 10).

Some strains of fungi belonging to the genera *Fusarium*, *Gibberella* and *Cylindrocarpon* have a high activity of this enzyme (8, 9, 11). For example, by incubating the *Fusarium oxysporum* cells for 24 hours at 30°C and a pH value of 7, D-pantolactone from the racemic mixture (700 g/l) is 90% hydrolyzed to D-pantoic acid, while the L-isomer remains unchanged (8, 9).

A simplified procedure ensures biocatalytic production of D-pantolactone, with an enantiomeric excess, from 3-hydroxy-2,2-dimethyl-propionaldehyde and hydrogen cyanide, followed by acid hydrolysis. As biocatalyst, the hydroxyl-nitrilase isozyme from *Prunus amygdalus* is used, the reaction being performed at a low pH value to avoid spontaneous formation of the racemic nitrile. A suitable biocatalyst for this process, which is stable and has a high activity to acidic pH, may be obtained from hydroxyl-nitrilase isoenzyme V (10, 12).

BIOSYNTHESIS OF PANTOTHENIC ACID

The development of genetic engineering techniques and the progress of DNA manipulation help researchers, who by modifying chromosomal genes or introducing additional extra chromosomal genetic material, managed the development new mutant strains with the ability to synthesize much larger amount of pantothenic acid as compared with the wild strains.

Gram positive bacteria *Coryne bacterium glutanicum*, used for large-scale production of amino acids (L-glutamic acid, L-lysine) was studied for the biosynthesis of vitamin B5. Thus, if the wild strain produces about 9 mg/l pantothenic acid, by chromosomal deleting the *ilvA* gene coding threonine-dehydratase and over expression combined *ilvBNCD* and *panBC* genes, scientists were able to accumulate more than 1 g/l vitamin in the supernatant (13, 14).

Saccharomyces cerevisiae has the capacity to produce endogenous β-alanine and, therefore, to biosynthesize de novo pantothenic acid, as long as *FMS1* gene, encoding amine oxidase that ensures the transformation of spermine in the β-

alanine, is over expressed (15). Over expression of *FMS1* caused excess pantothenic acid to be excreted into the medium, whereas deletion mutants required β-alanine or pantothenic acid for growth. White et al. concluded that yeast is naturally capable of pantothenic acid biosynthesis, and that β-alanine is derived from methionine via a pathway involving spermine.

For *Escherichia coli*, the responsible genes for encoding enzymes needed for the biosynthesis of vitamin B5 are: *panB*, *panC*, *panD* and *panE*. By overexpressing these genes, a new strain with superior pantothenic acid productivity has been developed (10, 11). Laudert and Hohmann used glucose as a substrate and β-alanine as a precursor and after 72 hours of fermentation was obtained a concentration of 66 g/l pantothenic acid. The main disadvantage of this process, beside the fact that β-alanine is added as a co-substrate, is that over 40 % of the amount of useful product does not come from carbohydrate substrate, but from the synthetized β-alanine.

A promising method for obtaining vitamin B5 is by fermentation processes using the *Bacillus subtilis* gram-positive bacteria. Normally, *Bacillus subtilis* synthesizes only small amounts of pantothenic acid required to refill their needs. By genetic engineering the over expression of the genes *panBCDE*, *ilvBNC* and *ilvD* of bacteria can be achieved, thereby obtaining a higher productivity - 86 g/l in only 48 hours, compared to the fermentation of mutant strain of *E. coli*. In addition, in the case of *Bacillus subtilis*, it is not necessary to add exogenous β-alanine. Therefore, the biotechnologies methods are a feasible alternative and economically solution in the production of vitamin B5 *vs.* chemical synthesis (10, 16).

The pantothenic acid obtained by these methods has to be further extracted from natural extracts or biosynthesis media. The separation of pantothenic acid can be carried out by crystallization, ion exchange, chromatography, and physical extraction (17-20). Further studies focused on the separation of pantothenic acid by reactive extraction, method that has been used for the recovery of biosynthesis products (organic acids, antibiotics, vitamins, amino acids etc.) from aqueous solution using an organic phase in which different extractants are added (21).

Although biosynthesis is an environmentally friendly and fairly cheap alternative to obtain vitamin B5, it is not currently applied to industrial level due to much lower productivity compared with chemical methods. Further efforts are needed to develop new strains whose metabolic flux to be directed mainly towards the synthesis of pantothenic acid, so as to ensure a higher yield (10).

CONCLUSIONS

Industrial production of pantothenic acid is based on chemical synthesis, but an attractive alternative for obtaining this compound, in terms of required steps and consumption of raw materials and energy, is biosynthesis by microorganisms.

With the use of chemical and genetic engineering, scientists were able to improve the properties of the biosynthetic product and also to achieve much higher production yields for pantothenic acid. By modifying chromosomal genes, *Coryne bacterium glutanicum* can produce more than 1 g/l pantothenic acid, compared with about 9 mg/l produced by the wild strain. Introducing additional extra chromosomal genetic material and over expressing some genes led to the development of new strains with superior pantothenic acid production. Thus, *Escherichia coli* can produce in 72 hours of fermentation 66 g/l pantothenic acid, using glucose as a substrate and β-alanine as a precursor, and *Bacillus subtilis* was able to produce 86 g/l vitamin B5 in

only 48 hours.

VISIBLE SPECTROPHOTOMETRIC METHOD FOR AMIODARONE

Andreea Bosînceanu[1], Grațiela Popa[1], Gladiola Țântaru[2], Iuliana Popovici[1]
University of Medicine and Pharmacy, „Grigore T. Popa" - Iasi

VISIBLE SPECTROPHOTOMETRIC METHOD FOR AMIODARONE (Abstract): Amiodarone is an antiarrhythmic agent used for various types of tachyarrhythmia, both ventricular and supraventricular (atrial) arrhythmia. A spectrophotometric method for the assay of amiodarone was established. Based on the reduction of potassium ferricyanide in hydrochloric acid medium to potassium ferrocyanide forming a blue colored complex ferric ferrocyanide with Fe (III) ions. The compound was most stable in a mixture of ethylic alcohol and water (2:1, v/v) and it had an absorption maximum at 725 nm. The data were according to the Lambert-Beer Law in the concentration range of 0.5-5.0 µg / sample: correlation and coefficient R = 0.99977, R^2 = 0.999541, slope of the line 0.12775, intercept 0.042077. The detection limit (DL) was 0.1032 µg / sample and the quantification limit (QL) 0.344µg/ sample. **Key words:** AMIODARONE; SPECTROPHOTOMETRY, VALIDATION.

Amiodarona, a class III of antiarytmic reagent has been clinically used as one of the most powerful antiarrhythmic drugs for the treatment of a wide variety of arrhythmias. Its main effect is to delay repolarization and to prolong the action potential duration of atrial and ventricular muscle without altering the resting membrane potential. Amiodarone thus lengthens the refractory period of atrial and ventricular myocardium, the atrioventricular node, and of the accessory pathways which mediate Wolff-Parkinson-White (WPW) syndrome.

This paper presents a new spectrophotometric quantitative method of amiodarone using as reagent potassium ferricyanide and ferric chloride in hydrochloric acid medium forming ferric ferrocyanide.

The proposed method is based on the reaction of amiodarone with ferric ferrocyanide in hydrochloric acid medium is released and it reduces the proposed reagent in a blue compound with a maximum of absorption of 725 nm.

The following protocol was set. 2 ml ferric ferricyanide solution was considered ideal for the reduction and the necessary acidity level of the reaction was obtained by adding 1 ml 2N hydrochloric acid solution. It was established that the absorbance could be read after at least 20 minutes after addition of all reagents, and the reaction product was stable for at least 30 minutes.

This paper presents the validation of the VIS spectrophotometric determination method for amiodarone.

MATERIAL AND METHODS

- Stock solution of amiodarone 0.1 mg/ml: 0.010 g amiodarone is dissolved in

100 ml ethylic alcohol. Standard solution with concentrations ranging between 0.5-5.0 μg/ml are prepared from this solution;

- $FeCl_3$ - 0.04% (m/v) aqueous solution;
- $K_3[Fe(CN)_6]$ - 0.02% (m/v) aqueous solution;
- main reagent: 1:1 mixture of $FeCl_3$ - 0.04% (m/v) aqueous solution and $K_3[Fe(CN)_6]$ - 0.02% (m/v) aqueous solution;
- HCl 2N solution;
- Spectrophotometer UV-VIS Hewlett-Packard 8453.

The proposed method for determining of amiodarone is based on the reduction of potassium ferricyanide in hydrochloric acid medium which forms ferric ferrocyanide when reacting to ferric chloride. The blue colored compound is most stable in a mixture of ethylic alcohol and water (2:1 v/v) and has an absorption maximum at 725 nm against a witness whose absorbance is negligible.

The reactions that take place:

$$Fe(CN)_6^{3-} + e^- \rightarrow Fe(CN)_6^{4-} \qquad E_{o\ ox.\ red} = 0.356V;$$

$$Fe(CN)_6^{4-} + 4Fe^{3+} \rightarrow Fe_4[Fe(CN)_6]^3;$$

$$Fe^{3+} + e^- \rightarrow Fe^{2+} \qquad E_{o\ ox.\ red} = 0.771V.$$

1 ml sample containing 0.5-5.0 μg/sample amiodarone is measured in a series of 5 ml volumetric flasks. 1 ml HCl 2N, 2 ml ferric ferrocyanide freshly prepared reagent is added to the sample and then it is brought to 5 ml with ethylic alcohol. The mixture is homogenized and it is left to rest for 20 minutes, then the absorbance of the blue compound is measured at 725 nm against a witness.

RESULTS AND DISCUSSION

In order to validate the VIS spectrophotometric method for the assay of amiodarone, the following parameters have been studied: the detection wavelength, the linearity, the detection and the quantification limit, the precision of the system, the precision of the method and the accuracy.

Establishing the optimum detection wavelength [4-7]

From the absorption spectrum of the colored compounds, we noticed that the formed complex shows a 725 nm a maximum of absorbance at a wavelength of when compared to the reagent and amiodarone alone as it is shown in Figure 1.

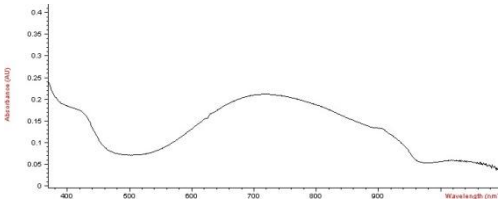

Fig. 1. Absorption VIS spectrum for the colored compounds

Linearity [4-7]

For the study the linearity of the method, we prepared amiodarone solutions by diluting the stock solution with distilled water in the 0.5–5.0 μg/sample concentration range. These solutions were processed according to the method. After obtaining the final product, we read the absorbance of each sample against a witness prepared in the same conditions at 725 nm. After processing the data through mathematical regression, a calibration curve could be obtained showed in the second Figure. The obtained data and the statistical evaluation are registered in table I and II.

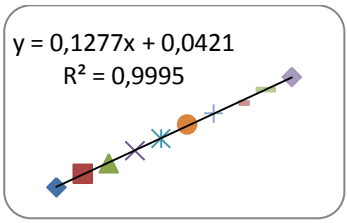

Fig. 2. Calibration curve

The equation of the calibration curve calculated through mathematical regression has the following profile:

Absorbance = 0.12775 concentration + 0.043077

TABLE I

The study of the linearity of the method

No	Conc. µg/ml	Absorbance				
		I	II	III	IV	Average
1.	0.5	0.10541	0.10563	0.10428	0.09888	0.10355
2.	1.0	0.17155	0.17461	0.17848	0.17408	0.17468
3.	1.5	0.22765	0.22521	0.23532	0.23042	0.22965
4.	2.0	0.30590	0.30255	0.26677	0.30866	0.29597
5.	2.5	0.35890	0.36288	0.36101	0.35985	0.36066
6.	3.0	0.43285	0.43601	0.43775	0.42559	0.43305
7.	3.5	0.48851	0.49473	0.49116	0.49220	0.49165
8.	4.0	0.54602	0.54824	0.53924	0.55502	0.54713
9.	4.5	0.61588	0.62043	0.61476	0.61021	0.61532
10.	5.0	0.66819	0.71276	0.67625	0.67168	0.68222

TABLE II

Linearity – statistical evaluation

Correlation coefficient (r)	0.999541
Regression coefficient (r^2)	0.99977
Standard error (SE)	0.0043946
Intercept	0.042077
Slope	0.12775

After the statistical evaluation of the linearity, the detection limit was determined that represents the minimum concentration of the compound in the sample that can be detected but not necessarily quantified using the formula (SE is the regression standard error):

LD = 3 x SE / slope = 0.1032 µg/sample

We have determined the quantification limit (LQ) that represents the minimum concentration of the amiodarone that can be determined with an acceptable precision and accuracy, in the described experimental conditions, it was calculated using the formula:

LQ = 10 x SE/ slope = 0.344 µg/sample.

Precision characterizes the consistency degree of the analytical results, when the analysis method is repeatedly applied to the same sample to be analyzed. It represents the performance degree of the methods and the instruments reflected on the results obtained under normal working conditions.

The performed studies for determining the precision include the precision of the system and the precision of the amiodarone determination method.

In order to evaluate the precision of the system, we have done 6 determinations for

the same sample (2 μg/sample), under the same experimental conditions and then we have calculated the standard deviation and the relative standard deviation (table III).

TABLE III
Precision of the system

No	Absorbance	No.	Absorbance	Statistical Data
1.	0.41667	6.	0.43294	Mean = 0.42452 SD = 0.006238 RSD = 1.47 %
2.	0.43193	7.	0.42417	
3.	0.42403	8.	0.42249	
4.	0.42361	9.	0.41765	
5.	0.41855	10.	0.43316	

After the statistical processing of the obtained data, we have found that the value of the relative standard deviation (RSD) is 1.4694 %, which shows that the system is precise.

Precision of the method

We have evaluated the precision of the method for a concentration range of ± 25 % compared to the target value (2 μg/sample). In order to validate the method (repeatability assessments) we have analyzed two sets of samples, each in different day, with at least 9 determinations covering the specific concentration area (tables IV and V).

The calculated confidence range for each individual value using equation (3) (for 8 degrees of freedom and a precision of 95%, t = 2.31) is 97.15 – 106.01 % because $x - (t\ SD) < \mu < x + (t\ SD)$ (3).

Calculating the confidence range for each individual value, for 8 degrees of freedom and a precision of 95% (t = 2.31), according to the equation (3), we have obtained: 98.48 – 104.95 %.

For the first set of determinations, we have obtained RSD = 1.89 %, for the second set RSD = 1.40 % and for both sets RSD = 1.65 %, values smaller than 2%, but closer to the precision of the system (RSD = 1.47 %). All these values confirm that the proposed method is precise.

TABLE IV
Precision of the method - first set

No	Theoretical concentration (μg/sample)	Absorbance	Calculated concentration (μg/sample)	%	Statistical Data
1	1.5	0.30393	1.5300	102.00	Mean = 101.58 SD = 1.9185 RSD = 1.89 %
2		0.30766	1.5600	104.00	
3		0.29896	1.4900	99.34	
4	2.0	0.36862	2.0500	102.50

8		0.42709	2.5200	100.80	
9		0.42336	2.4900	99.60	

TABLE V
Precision of the method – second set

No	Theoretical concentration (µg/sample)	Absorbance	Calculated concentration (µg/sample)	%	Statistical Data
1	1.5	0.30393	1.5300	102.00	Mean = 101.71% SD = 1.40 RSD = 1.38 %
2		0.30268	1.5199	101.33	
3		0.29895	1.4900	99.33	
4	2.0	0.36625	2.0309	101.55	
5		0.37036	2.0640	103.20	
6		0.36196	1.9965	99.82	
7	2.5	0.43456	2.5801	103.20	
8		0.43393	2.5750	103.00	
9		0.43082	2.5500	102.00	

The accuracy of the method is expressed by its recovery its expressed by a percentage of analyzed substance and it depends on the quality of the results due to the analysis method, the equipments, the reagents and the quality of the operations necessary for obtaining these results.

In order to determine accuracy of the amiodarone determination method, we used the addition method. Using the regression equation and the values of the corresponding absorbance, was calculated the concentration in µg/sample for each sample (table VI).

TABLE VI
The accuracy of the method

No	Theoretical concentration (µg/sample)	Absorbance	Calculated concentration (µg/sample)	Recovery %	Statistical Data
1	1.5	0.29897	1.4901	99.34	Mean = 100.14% Min = 98.00 % Max =102.35 %
2		0.29902	1.4905	99.37	
3		0.30297	1.5223	101.48	
4	2.0	036825	2.0470	102.35	
5		0.36285	2.0036	100.18	
6		0.36196	1.9965	99.82	
7	2.5	0.41838	2.4500	98.00	
8		0.42592	2.5106	100.42	
9		0.42558	2.5079	100.32	

The statistical data shown in Table VI shows that in the concentration range of 0.5 – 5.0 µg amiodarone per sample, the mean recovery is 100.14% (not less then 98.00 % and not more than 102.35 %). These values proved that the method was accurate.

CONCLUSIONS

Following the study carried out on the reaction of the ferric ferrocyanide with amiodarone a new spectrophotometric method for the assay of amiodarone is proposed.

The proposed method is simple, fast and it has the advantage of an increased sensitivity; the detection limit is 0.1032μg/sample and the quantification limit is 0.344μg/sample with amiodarone clohridate.

The analysis method was validated the setting optimum wavelength of detection at 725 nm. We also studied the linearity of the method in the range of 0.5– 5.0 μg amiodarone /sample, the correlation coefficient was r^2 = 0.99977, the accuracy (mean recovery =100.14%).the precision of the system (RSD = 1.47 %) and the precision of the method (RSD = 1.65 %).

In conclusion, the proposed method is linear, precise, accurate, simple and fast and it can be applied with good results for the assay with amiodarone in different pharmaceutical dosage forms.

INTERACŢIUNI ÎNTRE ANTICOAGULANTELE ORALE ŞI ALTE MEDICAMENTE ÎN UNITĂŢILE DE PRIMIRE URGENŢE – O ABORDARE FARMACOEPIDEMIOLOGICĂ

F. Apostoae[1], Liliana Tarţău[2], Cătălina-Elena Lupuşoru[2]

Disciplina de Farmacologie

INTERACTIONS BETWEEN ORAL ANTICOAGULANTS AND OTHER MEDICATION IN EMERGENCY DEPARTMENT-A PHARMACOEPIDEMIOLOGIC APPROACH (Abstract): Oral anticoagulants (OAC) are commonly used as a life-long therapy in the prevention of systemic embolism in patients with atrial fibrillation, valvular heart disease, prosthetic heart valves, and in the primary and secondary prevention of venous thromboembolism, in patients with acute myocardial infarction and angina pectoris. Drugs, herbs, and multivitamin supplements can alter the absorption, pharmacokinetics or pharmacodynamics of OAC. **Aim**: To investigate the possible interactions between oral anticoagulants and different drugs administered in patients in emergency department. Methods: This 1- year exploratory investigation on 93 patients on OAC (aged 30 – 85 years), admitted at two emergency departments of the Iasi „Sf. Spiridon" Hospital and Piatra Neamţ Hospital, consisted in their medical records analysis: diagnosis, recommended treatement. Data were scored and statistically analyzed by t-test (Windows Excel). The experimental protocol was in agreement with the recommendations of the Gr.T. Popa University Committee for Research and Ethical Issues. **Results and conclusions**: Analysis and statistical processing of data shows that during the study period 56 patients which received oral anticoagulant therapy associated with different other medication belonged to the 60 and 80 years age group. This finding suggests that the pathology is represented especially by atrial fibrillation and myocardial infarction. The correlation between the therapy consisting in OAC and sartan or nonsteroidal anti-inflammatory drugs and International Normalized Ratio (INR), revealed a high level of anticoagulation and an increase in hemorragic complications. **Key words**: ORAL ANTICOAGULANTS, DRUG INTERACTIONS, SARTANS

Anticoagulantele orale (ACO) sunt folosite în terapia pe termen lung, pentru prevenţia trombemboliilor sistemice la pacienţii cu fibrilaţie atrială cronică, cu boli cardiace valvulare sau cu proteze valvulare şi în tromembolismul pulmonar (1,2,3). Numeroase studii prezintă informaţii referitoare la interacţiuni ce apar între anticoagulantele orale şi diverse medicamente utilizate concomitent (4,5,6).

Controlul efectului anticoagulant se realizează prin măsurarea timpului de protrombină (timpul Quick), care evaluează activitatea complexului protrombinic, fiind sensibil, mai ales, în lipsa factorilor II, VII şi X ai coagulării (7). Datorită posibilelor

erori se recomandă folosirea ca reactiv de referinţă a unei tromboplastine sensibil standardizate (preparată din creier uman), exprimarea rezultatelor făcându-se prin raportul INR (International Normalized Ratio) şi prin determinarea timpului tromboplastinei parţial activate (aPTT) (8,9).

Lucrarea îşi propune să realizeze unele investigaţii ale interacţiunilor între anticoagulantul oral cumarinic (ACOC), acenocumarol şi alte medicamente recomandate pacienţilor aflaţi în situaţii de urgenţă.

MATERIAL ŞI METODĂ

Studiul s-a desfăşurat pe o perioadă de un an pe un număr de 93 de pacienţi (cu vârste cuprinse între 30 ani şi 85 ani), care au primit tratament cu anticoagulante orale. Cerecetările efectuate au cuantificat nivelul de anticoagulare al pacienţilor care au fost asistate în Unitatea de Primire Urgenţe (UPU) a Spitalului de Urgenţe „Sf. Spiridon" Iaşi şi Spitalul Judeţean de Urgenţe Neamţ (SJN), pentru diverse afecţiuni care au necesitat terapie cu ACOC pe termen lung şi care au primit şi alte medicamente, care au putut interacţiona cu acestea. S-au stabilit corelaţii clare între eficacitatea terapeutică a ACOC şi diverse medicamente utilizate simultan.

Criteriile de includere au fost: persoane cu domiciliul stabil în localitate, vârsta între 18-85 ani, prezentarea la UPU pentru efectuarea analizelor lunare sau de urgenţă, iar criteriile de exclu:dere au cuprins: vârsta sub 18 ani sau peste 85 ani, refuzul subiecţilor, date incomplete, persoane cu domiciliul în alte localităţi.

Culegerea datelor preliminare s-a efectuat cu ajutorul registrelor de consultaţii din UPU, a anchetei privind utilizarea anticoagulantelor orale, prin măsurători clinice şi determinări de laborator şi au luat în consideraţie sănătatea pacientului şi condiţiile de viaţă (vârstă, sex, ocupaţie); rezultate recente privind: timpul Quick (TQ), INR, aPTT efectuate în UPU, date referitoare la tratament, respectiv ACO, sartani sau antiinflamatoare nesteroidiene (AINS). Într-o etapă următoare, au fost definite cazurile şi expunerea, studiul urmărind şi măsurarea asocierii dintre comorbiditate ca factor de risc cu implicaţie în relaţia de cauzalitate. Studiul s-a efectuat cu acordul Comisiei Etice a UMF ''Gr.T. Popa'', Iaşi. Datele au fost centralizate şi prelucrate statistic cu ajutorul testului *t-Student* din Microsoft Office Excel.

REZULTATE ŞI DISCUŢII

1. Distribuţia pe sex. La SJ Neamţ, în perioada studiată, s-au prezentat un număr de 35 de pacienţi care au fost trataţi simultan cu ACOC şi sartani sau AINS, din care 22 au fost de sex masculin.În perioada studiată, la UPU a Spitalul „Sf. Spiridon" Iaşi s-au prezentat un număr de 58 de pacienţi, care au fost trataţi simultan cu ACOC şi sartani sau AINS, din care 30 au fost de sex masculin (tab. I).

TABELUL I

Distribuţia pe sex a pacienţilor incluşi în studiu.

Spitalul Judeţean PiatraNeamţ			**Spitalul „Sf. Spiridon" Iaşi**		
Sex	Nr.	%	Sex	Nr.	%
Masculin	22	62,9	Masculin	30	51,7
Feminin	13	37,1	Feminin	28	48,3
Total	35	100,0	Total	58	100,0

2. Distribuția pe grupuri de vârstă. În studiu au fost incluşi pacienţi cu vârste între 30 şi 85 de ani, care s-au prezentat la Unităţile de Primire Urgenţe. Cei mai mulţi dintre pacienţi aparţin grupei de vârstă cuprinsă între 70 şi 80 de ani, media de vârstă fiind de 64,5 ani la Spitalul Judeţean Neamţ (41,7%) şi 70,4 ani la Spitalul „Sf. Spiridon" Iaşi (36,2%).

TABELUL II

Distribuţia pe grupuri de vârstă a pacienţilor din cele două grupuri de studiu.

	Grupul de vârstă (ani)	Nr.	% *
Pacienţi	30 – 40	1	1,7
Spitalul „Sf. Spiridon" Iaşi	40 – 50	2	3,4
	50 – 60	8	13,8
	60 – 70	12	20,7
	70 – 80	21	36,2
	80	14	24,1
	Total	58	100,0

	Grupul de vârstă (ani)	Nr.	% *
Pacienţi	30 - 40	3	8,6
Spitalul Județean Piatra Neamţ	40 - 50	1	2,9
	50 - 60	4	11,4
	60 - 70	10	28,6
	70 - 80	13	37,1
	80	4	11,4
	total	35	100,0

*pentru valorile mai mici de 10, proporțiile sunt orientative.

3. Distribuția pacienților în relație cu diagnosticul. Centralizarea datelor a arătat că la UPU a SJ Neamţ, diagnosticul principal al pacienţilor a fost FiA (42,9%), urmat de accidente după administrarea de ACOC (17,1%) şi de IMA (14,3%) (tab. III).

Studiul efectuat a evidenţiat faptul că la UPU a Spitalului „Sf. Spiridon" Iaşi, cea mai mare parte din pacienţi prezentau FiA (58,6%) şi, în ordine descrescătoare a incidenţei, IMA (25,9%) şi accidente după administrarea de anticoagulante orale ACOC (6,9%)(tab. IV).

TABELUL III

Distribuţia în relaţie cu diagnosticul pacienţilor de la UPU a SJ Neamţ

Pacienți	Afecțiune	Nr.	% *
Spitalul Județean, Piatra Neamţ	fibrilaţie atrială (FiA)	15	42,9
	infarct miocardic acut (IMA)	5	14,3
	tromboză venoasă profundă (TVP)	1	2,9
	tromboembolism pulmonar (TEP)	2	5,7
	accident vascular cerebral (AVC)	2	5,7
	accidente după ACOC	6	17,1
	proteză valvulară	2	5,7
	altele	2	5,7
	Total	35	100,0

*pentru valorile mai mici de 10, proporțiile sunt orientative.

TABELUL IV

Distribuţia în relaţie cu diagnosticul pacienţilor de la UPU Spitalul „Sf. Spiridon" Iaşi

	Afecţiunea	Nr.	% *
Pacienţi **Spitalul „Sf. Spiridon" Iaşi**	FiA	34	58,6
	sindroame coronariene acute (SCA)	15	25,9
	TVP	2	3,4
	AVC	2	3,4
	accidente după ACOC	4	6,9
	proteză valvulară	1	1,7
	Total	58	100,0

*pentru valorile mai mici de 10, proporţiile sunt orientative.

4. Distribuţia pacienţilor în relaţie cu medicaţia primit. Dintre cei 35 de pacienţi incluşi în studiu care s-au prezentat la UPU Piatra Neamţ cu tulburări de coagulare, 12 au fost trataţi cu acenocumarol (Sintrom(R) sau Trombostop(R)), 12 cu ACOC şi AINS, iar 11 au primit tratament cu ACOC şi sartani (tab. V).

TABELUL V

Distribuţia în funcţie de tratament pacienţilor de la UPU din cele două spitale

Pacienţi	Tratament	Nr.	%
Spitalul Judeţean Piatra Neamţ	ACOC	12	34,3
	ACOC+AINS	12	34,3
	ACOC+sartani	11	31,4
	total	35	100,0
Spitalul Clinic de Urgenţă „Sf. Spiridon" Iaşi	ACOC+sartani	27	46,6
	ACOC+AINS	24	41,4
	ACOC	7	21,1
	total	58	100,0

Dintre cei 58 de pacienţi incluşi în studiu care s-au prezentat la UPU „Sf. Spiridon " Iaşi cu tulburări de coagulare, 27 au primit tratament cu ACOC şi sartani, 24 cu ACOC şi AINS, şi 7 doar cu acenocumarol (Trombostop(R)).

5. Corelaţii între diagnostic, sex, tratament şi TQ, INR, aPTT INR este parametrul cel mai utilizat în evaluarea eficacităţii terapiei cu ACOC. Riscul complicaţiilor hemoragice sau tromboembolice creşte dacă INR este în afara intervalului terapeutic recomandat.

Centralizarea datelor studiului de la UPU Piatra Neamţ privind tipul de tratament primit de pacienţi, evidenţiază faptul

că există o corelaţie pozitivă (p<0,01) între tipul de tratament şi nivelul INR şi negativă pentru aPTT, la persoanele care au primit concomitent ACOC şi AINS, dar şi la cei care au utilizat ACOC şi sartani. Astfel, se observă că nivelul INR este crescut, ca urmare a interacţiunilor medicamentoase apărute, atât la cei care sunt trataţi simultan cu ACOC şi sartani, cât şi la cei care au primit ACOC şi AINS (tab. VI).

TABELUL VI

Corelaţii – UPU a SJ Neamţ

Elemente pentru corelaţii	Indicatori statistic-matematici	Diagnostic	Distribuţia pe sex	Tratament	TQ	INR	aPTT
Diagnostic	Corelaţie Pearson	1	,218	-,198	,006	,122	,035

	N	34	35	24	35	35	35
** Corelaţia este semnificativa la nivelulul 0,01							

Studiul efectuat la UPU „Sf. Spiridon” Iaşi evidenţiază faptul că există o corelaţie pozitivă (p< 0,05) între tipul de tratament şi nivelul INR, TQ şi negativă pentru aPTT, la persoanele care au primit concomitent ACOC şi AINS, dar şi la cei care au utilizat ACOC şi sartani. De asemenea, există o corelaţie semnificativă statistic între nivelul INR, TQ şi diagnosticul principal al pacienţilor (p< 0,01). Astfel, se constată că nivelul INR este crescut, ca urmare a interacţiunilor medicamentoase apărute, la pacienţii trataţi simultan cu ACOC şi sartani, cât şi la cei care au primit ACOC şi AINS (tab. VII).

Într-un studiu se arată existenţa de interacţiuni medicamentoase între ACOC şi AINS din 112 pacienţi 46% au prezentat creşterea INR peste nivelul terapeutic după introducerea AINS (13). Fukuda T. et al (12) au stabilit influenţa metabolismului candesartanului asupra ACOC într-un studiu in vitro realizat la Şcoala de Ştiinţe Farmaceutice de la Universitatea Osaka.

CONCLUZII

Utilizarea anticoagulantelor orale concomitent cu alte tratamente, cu AINS sau cu sartani, fără modificarea dozelor iniţiale, a determinat creşterea nivelului de anticoagulare la aceşti pacienţi, obiectivat prin creşterea nivelurilor INR, TQ şi prelungirea aPTT. Din studiul efectuat la cele două UPU a două spitale judeţene din Moldova se concluzionează următoarele:

- se observă un număr mai mare de pacienţi de sex masculin, la ambele UPU, cu un plus la Piatra Neamţ, respectiv, 62,7% bărbaţi, faţă de Iaşi, 51,7% bărbaţi;

- grupa de vârstă a pacienţilor este asemănătoare la cele două spitale, dar cu o medie de vârstă mai mare pentru pacienţii de la Iaşi, respectiv 70,4 ani, faţă de 64,5 ani, la Neamţ;

- în ceea ce priveşte diagnosticul prin-

cipal pentru care s-au utilizat ACOC, rezultatele arată că FiA este cea mai des întâlnită la pacienţii prezentaţi la ambele spitale judeţene, urmată de IMA în ambele UPU;

- nivelul mediu al INR la pacienţii sosiţi la cele două UPU este asemănător (4,51 la Neamţ, faţă de 4,58 la Iaşi);

- corelaţiile semnificative statistic sunt asemănătoare la cele două spitale judeţene, între nivelul INR, TQ, şi tipul de tratament primit de pacienţi.

OPTIMIZATION OF TOPICAL GELS WITH BETAMETHASONE DIPROPIONATE: SELECTION OF GEL FORMING AND OPTIMAL COSOLVENT SYSTEM (Abstract): The purpose of these studies was to develop a 0.05 % betamethasone gel characterized by physical-chemical stability and good release properties. The preliminary studies were designed to select the gel-forming agents and the excipients compatible with betamethasone dipropionate. In order to formulate a clear gel without particles of drug substances in suspension, a solvent system for the drug substance was selected. The content of drug substance released, the rheological and in vitro release tests were the tools used for the optimal formulation selection. A stable carbomer gel was obtained by solubilization of betamethasone dipropionate in a vehicle composed by 40 % PEG 400, 10 % ethanol and 5 % Transcutol

The use of topical corticosteroids started the revolutionary management of skin diseases. In topical formulations, betamethasone dipropionate (BDP), a synthetic adrenocorticosteroid, is indicated for relief of the inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses.

For topical formulation, the vehicles have a significant influence in stability and efficiency. The excipients could act by increasing and optimizing the thermodynamic activity of drug in the vehicle and promote the release from vehicle to the skin (1, 2, 3). The incompatibilities between drug substance and excipients were the primary cause of degradation reactions.

The goal of these studies was to develop a 0.05 % betamethasone (B) gel by selecting the excipients capable to assure, in the same time, the solubilization of BDP, chemical stability and good release properties of drug from vehicles.

MATERIAL AND METHODS

Betamethasone dipropionate (Farmabios, Italy); Benzyl alcohol (Brenntag Tesenderlo Chemie NV, Germany); Carbomer *Carbopol® Ultrez 10* (Lubrizol Corporation, USA); Caprylocaproyl Macrogolglycerides *Labrasol®* (Gattefosse, Canada); Diethylene Glycol Monoethyl Ether *Transcutol®* (Gattefossé, France); Dimethyl sulfoxide *DMSO* (Gaylord Chemical, Germany); Glycerol (Evayap International, Turkey); Hexylene Glycol - *HG* (Adiego Hnos. S.A., Spain); Hydroxypro-

pyl methylcellulose (HPMC) - Metholose 60-SH 4000, Shin-Etsu, Japan; Isopropyl myristate - IPM (Cognis, Germany), Macrogol 400-*PEG 400* (Sasol, Slovakia); N-methyl pyrrolidone (NMP) *Pharmasolve*® (ISP, Switzerland); Poloxamer 407 *Lutrol*® F 127 (BASF, Germany), Propylene glycol *PG* (SC Oltchim, Romania) and Sodium alginate *Manucol LKX* (ISP, Germany) were used. All chemicals were either analytical or pharmaceutical grade and they were used as received.

Preparation of gels

For the preparation of 8 gels formulation (G-G8), 0.05 % BDP was suspended in four types of gel forming agents, at two different concentrations each: carbomer, poloxamer, metholose and sodium alginate (Na alginate).

For the formulations coded G9 to G32, the BDP was first suspended/dissolved in different mixtures of aqueous excipients with humectants, solvents or permeation enhancers and then incorporated in the gel mass (4).

BDP suspensions in different aqueous excipients

Suspensions of 0.05 % B (w/v) were prepared using binary mixtures (1:1, w/w) of water and different excipients: DMSO, Glycerol, HG, IPM, Labrasol, NMP, PEG 400, PG and Transcutol® (Table II). The suspensions were stored at temperatures of 40±2°C and 75±5 % RH (relative humidity) for 3 months.

In Vitro Drug Release Studies

The *in vitro* release studies were carried out in static type diffusion cells having 15-mm orifice (1.76 cm^2 diffusion area) and 7 mL capacity. The studies were performed using synthetic nylon membranes (25 mm diameter, 0.45 μm) and hydroalcoholic receptor medium (phosphate buffer pH 7.4 : ethanol 1:1, w/w), thermostated at constant temperature (35±0.5°C). Samples were collected every hour, for six hours and the BDP content was analyzed spectrophotometrically at 254 nm. The total amount of BDP was determined in each cell. The micrograms per cubic centimeter released at each time interval were plotted against square root of time. We determined the slope of the line (R, release rate), using linear regression.

Determination of Viscosity

A rotational viscometer Brookfield RVDV II + Pro and adapter (Helipath Stand with TC spindle), rotated at a speed of 7 rpm, was used to measure the apparent viscosity of the preparations.

Related substances content

For evaluating the B related substance content (any impurity - AI and total impurities - TI), a validated HPLC analytical method was used. The analytical equipment consisted of a liquid chromatograph equipped with UV detector and recorder. The chromatographic conditions were: chromatographic column: Lichrosorb RP 18, 250×4,6 mm, 5 μm; mobile phase – acetonitrile:water 40:60 (v/v); flow rate: 1.0 mL/min.; detector: UV at 254 nm; temperature: 30°C. European Pharmacopoeia 6.0 specifies the following limits for related substances in the monograph "Betamethasone dipropionate": any impurity - max. 1.50 %; total impurities - max. 2.50 % (5,6, 7).

RESULTS AND DISCUSSION

In the first stage of studies, one series of 8 gels was prepared and evaluated after 24 hours and after 1 year from preparation (maintained at 25±2°C) (Table I).

The poloxamer (22 %), metholose and sodium alginate do not allow drug extrac-

tion from gel structure in the sample analytical preparation before HPLC analysis. In G4 formulation, the high level of related substances reflects the incompatibilities between poloxamer and BDP. The sodium alginate forms unaesthetic gels with slight brown color and with filaments in their structure. The optimum gel forming agent for BDP gels was carbomer.

With the purpose of dissolving BDP and obtaining a gel without particles in suspension, the compatibility of BDP with a series of liquid excipients with humectants, solvents or permeation enhancers was tested (8, 9, 10, 11). Composition of suspensions is presented in table II.

The measure of compatibility was the level of related substances evaluated initially and after 3 months, when keeping the suspensions at 40±2°C and 75±5 % RH (Table II). The lower values of B related substances were recorded when using PEG 400 and Transcutol. These excipients were selected for the solubilization of BDP in gel formula. In stage two of the studies, a second series of gels was prepared with

different amounts of above-mentioned excipients. PEG 400 used as unique solvent, in concentrations between 5 and 60 %, was not able to maintain the drug substance dissolved.

Adding Transcutol to the formula determined the formation of a clear gel, without particles in suspension (G23, G25, G26). The gels without drug crystals have the disadvantage of high levels of PEG 400 (over 50 %), excipient with irritating properties in topical applications. Consequently, to reduce the PEG 400 content, the formula G19 was selected for optimization. To this formula, different amounts of ethanol were added (5 to 15 %).

CONCLUSIONS

The carbomer was the gel-forming agent compatible with BDP and which allows the extraction of drug and proper use of analytical methods. The effect of low release properties of carbomers is neutralized by PEG 400 and ethanol, excipients with good solvent properties for BDP. Supplementary to the molecular dissolution of drug substance, the use of Transcutol, excipient which is

also a permeation enhancer, confers the advantage of therapeutic efficiency (3, 9). The 0.05 % B gel formula characterized by solubilization of drug substance in a vehicle composed by 1 % carbomer, 40 % PEG 400, 10 % ethanol and 5 % Transcutol represents the most stable formulation obtained during this research. After 6 months of accelerated stability studies, the content of related substances was below the maxim admissibility level specified in the European Pharmacopoeia. By extrapolation, the formula may be considered stable for 2 years. The formula also presents optimum physical properties (appearance and viscosity) for topical application.

SURFACE PROPERTIES AND CHARACTERISTICS OF PU-PTHF/MDI/HPC POLY (ETHER)URETHANE FOR CARDIOVASCULAR PROSTHESIS (Abstract): The polyurethanes are very used materials for medical devices. Their segmented block-copolymeric structures endows them a wide range of versatility in terms of tailoring their physical properties, and tissue compatibility. **Material and method**: A new polyether-urethane based material (PU-PTHF/MDI/HPC) was studied on bio-integration capacity in cardiovascular applications. In this respect, surface and bulk structure analysis, albumin and fibrinogen adsorption (in noncompetitive and competitive condition) and thrombogenicity have been evaluated. It was found that PU-PTHF/MDI/HPC surfaces had different roughness and bulk interconnected, well developed porous structure. As protein adsorption properties, preferential adsorption for albumin of material was observed. **Results**: Thus, 0.280 ± 0.04 mg/cm^2 and 0.260 ± 0.01 mg/cm^2 of albumin adsorb on PU-PTHF/MDI/HPC in noncompetitive and competitive conditions, while fibrinogen adsorption was 0.044 ± 0.02 mg/cm^2 and 0.040 ± 0.01 mg/cm^2. The clot amount test experiment have shown that clot weight of control blood was 24.8 ± 2.03 mg, the clot weight formed by polyurethane was 28.4 ± 2.93 mg and the clot weight formed by thrombogenic positive control (collagen membrane) was 42.5 ± 3.50 mg. **Conclusions**: From our study we could conclude: 1 - PU-PTHF/MDI/HPC polyurethane membranes have two-interface structure that could be advantageous for cavitary or tubular medical devices; 2 – the protein adsorption results and clot formation test revealed a thromboresistent behavior of PU-PTHF/MDI/HPC, appropriate for cardiovascular applications. **Key words:** POLYURETHANE, PROTEIN ADSORPTION, THROMBORESISTANCE, CARDIOVASCULAR APPLICATIONS

Polimerii poliuretanici sunt o clasa importantă de materiale sintetice, utilizate pe larg în domeniile biomedicale. Numeroase produse comerciale pe bază de polimeri poliuretanici cu aplicaţii cardiovasculare precum grefe vasculare, valve cardiace, componente ale inimii artificiale, baloane pentru angioplastii, catetere sau altele sunt în prezent disponibile (1,2,3,4). Principalele avantaje ale acestui tip de polimer sunt datorate structurii bloc-segmentate, în care alternează segmentele rigide şi cele flexibile. Astfel, se pot obţine numeroase structuri cu proprietăţi mecanice, fizico-chimice şi de suprafată diferite, în funcţie de componentele de pornire a sintezei, a modului de conducere a reacţiei de polimerizare, precum şi de metodele de obtinere a suporturilor (filme, bureţi, spume etc.). Diversitatea poliuretanilor, explicată prin varietatea segmentelor rigide şi

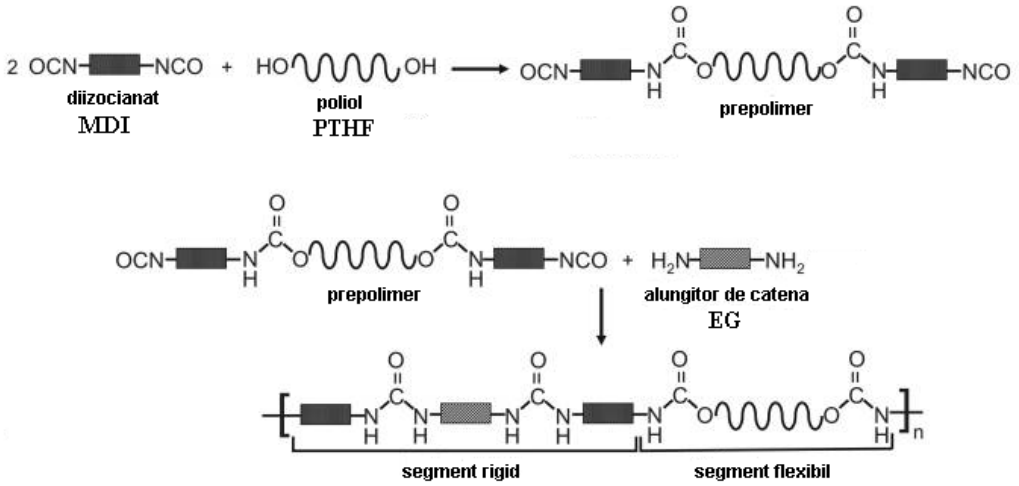

Fig. 1. Reprezentarea schematică a principiului de obţinere PU-PTHF/MDI/HPC

a celor flexibile utilizate la sinteza diblоc--polimerilor, este imbogăţită continuu datorită tehnologiilor noi de obţinere a structurilor mai complexe, de tipul tribloc sau a celor de hidrogeluri (5,6).

În calitate de segmente flexibile, la sinteza poliuretanilor sunt utilizaţi macrodiolii de tip: polietilenglicol (PEG), polietilenoxid (PEO), polipropilenoxid (PPO), policaprolactonă (PCL) şi multe altele. Pentru segmenele rigide sunt frecvent utilizaţi diizocianaţii de tip: diizocianatohexan (HDI), diizocianatobutan (BDI), difenilmetandiizocianat (MDI) şi altele. Prin interacţia celor două componente se obţine un prepolimer, care este extins mai apoi cu ajutorul unui alungitor de catenă de tipul etilenglicolului (EG) a butandiolului (BD) şi a altor molecule cu proprietăţi de legare asemanatoare.

Deşi poliuretanii sunt o clasă de materiale cu o capacitate structurală nelimitată, întrunirea concomitentă a cerinţelor mecanice, precum şi a celor de biocompatibilitate (in particular a celor de hemocompatibilitate) este greu de realizat. Numeroase studii din ultimii ani au fost dedicate găsirii unor formule ideale de structură pentru susţinerea unor funcţii biologice concrete (2,7, 8,9), capitol din care face parte şi această cercetare. Astfel, în aceasta lucrare un nou poliuretan di-bloc segmentat, modificat prin amestec fizic cu derivatul celulozic – hidroxipropilceluloza (HPC) a fost studiat pentru caracteristicile şi proprietăţile sale de integrare functională la interfaţa cu sângele. Materialul a fost selectat în cadrul unor studii anteriaore, ca fiind unul potrivit din punct de vedere mechanic si fizico-chimic pentru acest tip de aplicatii (10,11,12,13,14).

MATERIAL ŞI METODĂ

Materialul poliuretanic luat în studiu a fost obţinut prin reacţia de polimerizare folosind N,N-dimetilformamida (DMF, Fluka) ca solvent. Pentru sinteza poliuretanului, în calitate de macrodiol a fost utilizat polytetrahidroxifuranul (PTHF, Mn = 2,000 g/mol), iar ca diizocianat - 4',4'- difenilmetandiizocianatul (MDI, Merck). Derularea reacţiei de sinteză si a proprietăţilor fiyico-chimice obţinute a fost obictul studiilor anterioare (12,13). Etapelor de sinteză a materialului sunt reprezentate schematic a figura 1. Polimerul sintetizat, notat prin PU-MDI/PTHF/HPC a fost precipitat în apă caldă iar apoi uscat în condiţii de vacuum timp de câteva

zile, pentru obţinerea membranelor cu grosimea de aproximativ 1 mm.

Morfologia de suprafată şi structura internă a PU-MDI/PTHF/HPC a fost studiată cu ajutorul metodei de microscopia electronic de baleaj (SEM), utilizând procedura standard de pregătire a probei, descriesă în literatură (15). Analiza SEM a fost efectuată cu ajutorul microscopului electronic de baleaj VEGA TESCAN, in sistem de vid înaltă (high vacuum – HV) la o tensiune de acceleraţie a electronilor de 30 kV.

Sarcina electrică de suprafaţă a materialului a fost măsurată prin determinarea potenţialului zeta, cu ajutorul analizatorului electrocinetic SurPASS, Anton Paar GmbH. Principiul metodei se bazează pe masurarea potenţialul de interfaţă dintre stratul imobil, purtător de sarcină electrică (polimerul) şi cel difuz, cunoscut ca strat dublu electric creat la interfaţa polimer - lichid (16). Astfel, doua filme poliuretanice cu dimensiuni de 1,5 x 1,0 cm au fost montate pe cele 2 placi de teflon ale aparatului. Pentru fiecare determinare placile erau aduse faţă-în-faţă, astfel încât între cele două suprafeţe polimerice se crea un microcanal prin care se forta trecerea unui electrolit cu debit al fluxului de 80 ml/min la o presiune de 300 mbar În calitate de electrolit s-a folosit o solutie 0,1M de NaCl. Valoarea potenţialului zeta se obţinea ca urmare a trecerii prin sistem a soluţiei de electrolit la interfaţa probei de analizat în direcţii alternative de patru ori (de două ori în fiecare direcţie). Valoarea potenţialului zeta s-a calculat utilizând ecuaţia Fairbrother–Mastin (ecuaţiile 1 şi 2), luându-se în considerare şi efectul conductivităţii suprafeţei.

$$\zeta = \frac{dU}{dp} \times \frac{\eta}{\varepsilon \times \varepsilon_0} \times K \quad (1)$$

unde: ζ - potenţialul zeta, dU/dp - panta potenţialului de electrofiltrare şi presiune, η - vâscozitatea electrolitului, ε_0 - permitivitatea vidului, ε - constanta dielectrică a electrolitului,

$$K = \frac{L}{A \times R} \quad (2)$$

unde: L - lungimea canalului de electrofiltrare, A - secţiunea canalului de electrofiltrare, R - rezistenţa internă a celulei de măsurare.

Pentru adsorbţia de proteine, albumina serică bovină (BSA, Sigma-Aldrich) şi fibrinogenul (fibrinogen liofilizat, > 95% coagulabil, Sigma-Aldrich) au fost utilizate.

Adsorbţia de albumina a fost determinată prin metoda indirectă, dozând concentraţia albuminei în soluţie fiziologică (4,5 mg/ml BSA în 0,9% NaCl), înainte şi după incubarea cu polimerul. Materialul cu o suprafaţă totală de 1 cm^2 era incubat într-un volum de 0,5 ml soluţie BSA, timp de 30 min, în condiţii de temperatură constantă, de $+37^0$C şi agitare orbitală de 150 rot/min. Înainte de incubare, probele de polimer erau hidratate în soluţie ser fiziologic steril. Dozarea albuminei s-a efectuat folosind metoda imunoturbidimetrică, cu anticorpi monospecifici pentru albumină, furnizati de kitul DiaLab (Austria). Pentru metodologia de dozare s-a respectat protocolul anexat kitului. Măsurătorile spectrofotometrice au fost efectuate utilizând spectrofotometrul UV-VIS Piccos 05. Formula de calcul pentru determinarea albuminei adsorbite a fost următoarea:

$$Proteina\ adsorbită\ (mg/cm^2) = (Ci - Cp)\ x\ V\ /\ S \quad (3)$$

unde, Ci şi Cp sunt concentraţiile iniţială şi cea de postincubare a soluţiei de proteină cu materialul poliuretanic, V – volumul de incubare a probei, iar S – suprafaţa probei incubate.

Ca şi în cazul albuminei, adsorbţia fibrinogenului a fost determinată prin metoda indirectă. Concentraţia soluţiei de fibrinogen a fost una specifică intervalului de valori normale în sânge, respectiv 3 mg/ml. Pentru dozarea fibrinogenului a fost utilizată metoda turbidimetrică Vincent, cu sulfat de sodium anhidru (17). Masuratorile spectro-

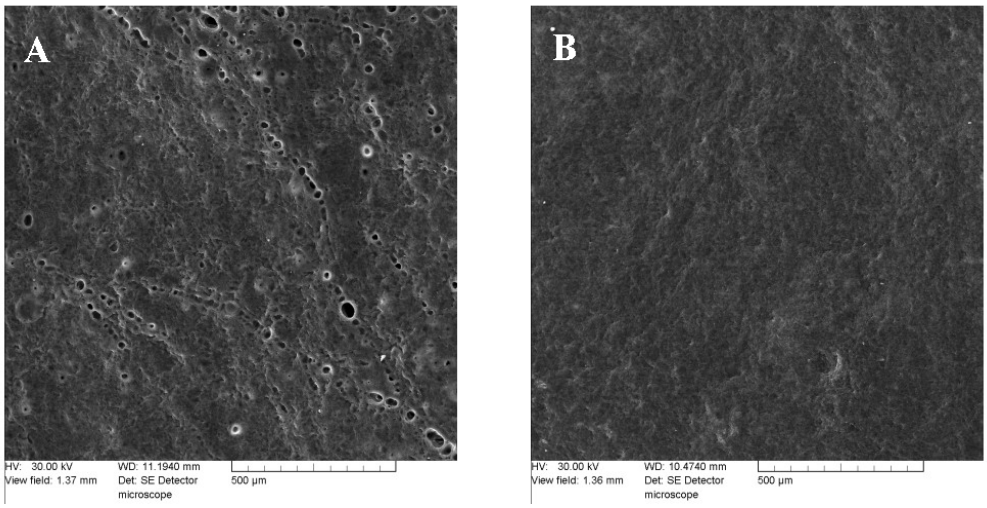

Fig. 2. Morphologia de suprafaţă a poliuretanului PU-PTHF/MDI/HPC
(*A* – faţa inferioara ; *B* – faţa superioară)

fotometrice au fost efectuate cu ajutorul spectrofotometrul UV-VIS Piccos 05. Formula de calcul pentru dozarea fibrinogenului a fost asemanatoare cu cea pentru calculul albuminei (ecuatia 3).

Activitatea trombogenă a materialului fost estimată cu ajutorul testului de formare a cheagului din sângele integral, *in vitro*, folosind metoda Nose (18) modificată în laborator şi descrisă în cercetarile noastre anterioare (11). Metoda reflectă capacitatea totală de coagulare a sângeli şi constă în incubarea unei suprafeţe de material (1 cm^2) cu 0,5 ml sânge integral (recoltat pe citrat de sodiu 3,8%), în condiţii de 37^0C timp de 30 min. La expirarea timpului de incubare, sângele era recalcifiat cu 0,05ml soluţie 0,1M $CaCl_2$, iar cheagul obţinut după 4 min de recalcifiere era cântărit cu ajutorul unei balanţe analitice. Rezultatul era comparat cu cel obţinut pentru sângele martor, incubat în aceleaşi condiţii, dar fără polimer.

REZULATE ŞI DISCUŢII

Din observaşiile privind caracteristicile morfologice de suprafaţă ale poliuretanului PU-PTHF/MDI/HPC (fig. 2) se poate observa că filmul poliuretanic exprimă două feţe cu porozitate şi rugozitate diferită. Structura bifacială este consecinta procesului de precipitare în apă.

Structura intrenă a materialului este reprezentată în figura 3. În imagine se pot observa pori de dimensiuni şi forme diferite. Se pot distinge : 1 - pori mari, cu o formă alungită, cu dimensiuni longitudinale cuprinse între 50 şi 500 μm şi cu dimensiuni transversale cuprinse între 50 şi 150 μm, formaţi ca urmare a pătrunderii, avansării şi fuziunii picăturilor de apă în polimer în timpul procesului de precipitare (fig. 3 A şi B) ; 2 - pori medii, de formă sferică, cu o distribuţie uniformă in întreaga grosime a materialului, cu dimensiuni situate în jurul valorii de 50 μm (fig. 3 C) ; 3 - pori foarte mici, cu diametrul de 1-4 μm (fig. 3 D). Din figura 3 se poate observa, de asemenea, că structura poarasă are forma unei reţele tridimensionale interconectate, permiţând din punct de vedere arhitectural şi dimensional invazia celulară, transferul de mase sau neovascularizarea. Mai mult decât atât, ca urmare a unei orientări bifaciale (asimetrice în raport cu cele doua feţe) a porozităţii, acest material poate

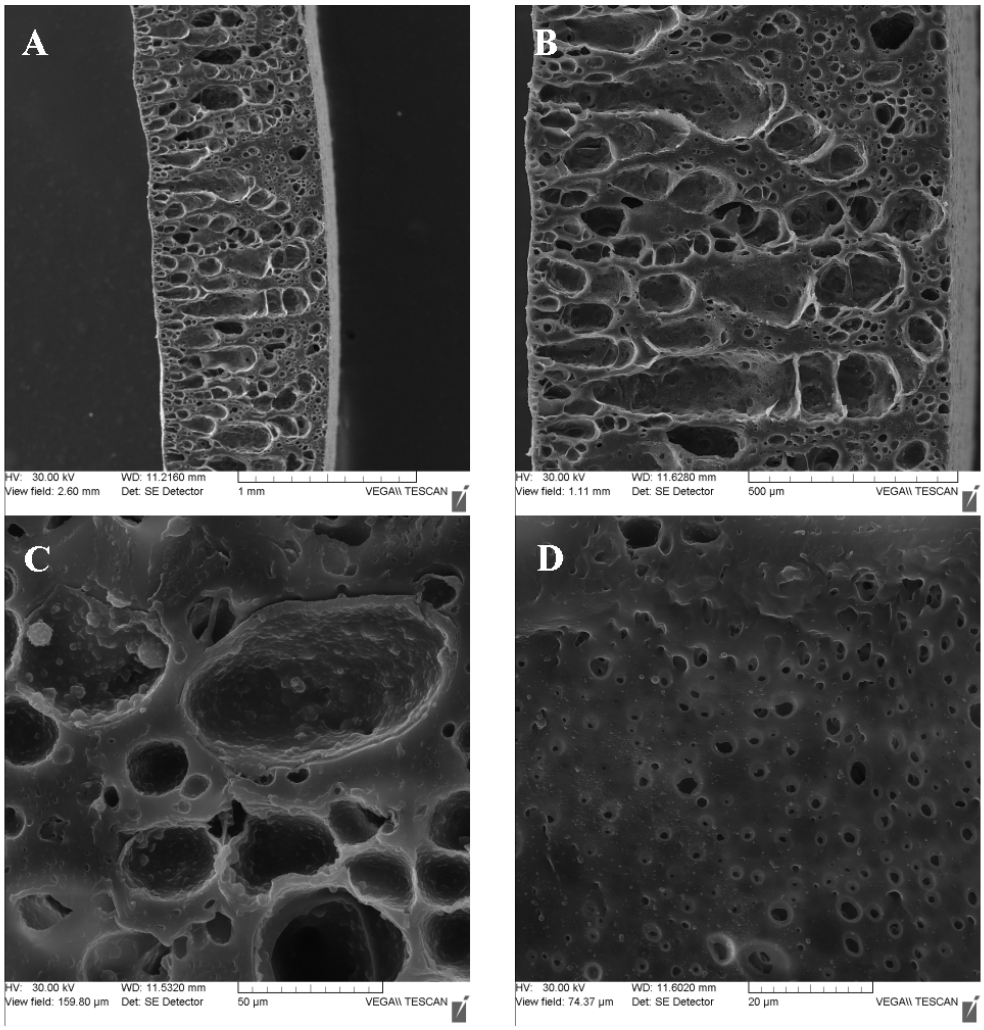

Fig. 3. Secţiune prin filmul poliuretanic PU-PTHF/MDI/HPC. Imagini de microscopie electronică de baleaj (SEM) (*A, B, C şi D* – putere de mărire diferită (scara alăturată fiecărei imagini)

fi util în proiectarea unor dispositive implantabile cu dublă interfaţă (de formă tubulară sau cavitară) pentru care este importantă porozitatea şi rugozitatea redusă orientată spre partea luminală sau cavitară şi porozitatea crescută orientată spre spaţiile interstiţiale. Acest tip de structură, dar şi proprietăţile elastice ale acestui material (9), pot fi considerate caracteristici favorabile pentru o integrare structurală corespunzătoare a materialului în cadrul unui tesut biologic.

Studiile privind capacitatea de integrare funcţională în cadrul potenţialelor aplicaţii cardiovasculare s-au axat pe determinarea unor proprietăţi de suprafaţă importante pentru biocompatibilitate, dar în special pentru hemocompatibilitate. Sarcina de suprafaţă, se ştie, determină iniţierea şi evoluţia fenomenelor nespecifice şi imediate, care au loc la interfaţa unui material sintetic cu ţesutu-

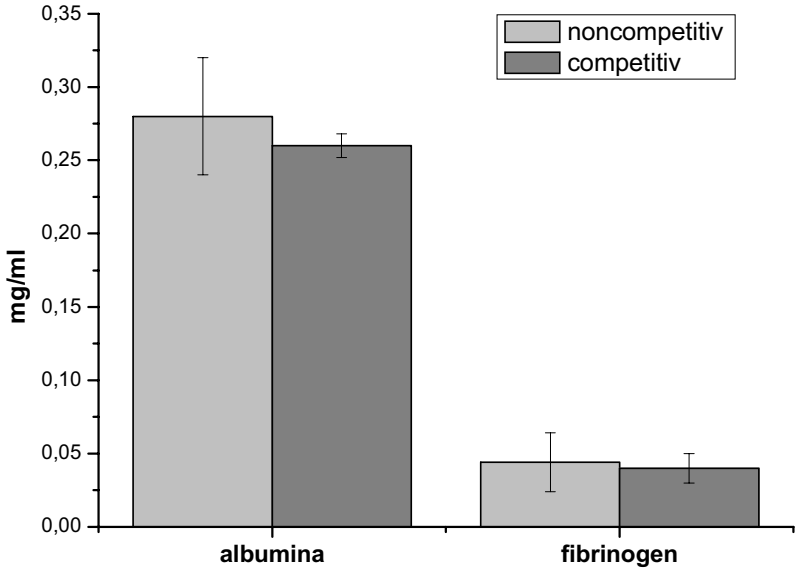

Fig. 4. Adsorpţia de albumină şi fibrinogen în condiţii noncompetitive şi competitive

rile vii. Aceasta intervine în adsorbţia proteinelor din fluidele biologice sau lichidele interstiţiale, ceea ce duce la activarea suprafaţei materialului. Astfel, afinitatea materialului pentru un anumit tip de proteine il poate vulnerabiliza, expunându-l atacului celular sau fenomenelor trombogene sau, din potrivă, il poate functionaliza în sensul biocompatibilizării - prin stimularea migrării, adeziunii şi populării cu celule funcţionale specifice. Este considerat, în general, că o suprafaţă încărcată negativ este un criteriu de biocompatibilitate, în timp ce sarcina de suprafaţă pozitivă favorizează denaturarea conformaţională a proteinelor adsorbite, expunând domeniile funcţionale din miezul hidrofob pe suprafaţa moleculei, astfel ducând la activarea reactiilor de corp străin sau a celor de coagulare la interactiunea cu sângele (19).

În studiul nostru, sarcina de suprafaţă exprimată de materialului PU-PTHF/MDI/HPC la un pH fiziologic de 7,3-7,4 a fost de +0,78 mV. Având în vedere că valoarea potenţialului zeta obţinută de noi a fost aproape de zero şi luând în consideraţie valorile descrise în literatură pentru alte tipuri de materiale (20), putem spune că suprafată PU-PTHF/MDI/HPC este neutră din punct de vedere electric.

Efectul unui potenţial aproape neutru asupra adsorbţiei de proteine a fost în continuare studiat pentru două proteine sanguine importante – albumina şi fibrinogenul. Rezultatele de adsorbţie obţinute în condiţii noncompetitive (soluţii fiziologice simulate simple) şi competitive (soluţie fiziologică simulată mixtă) sunt ilustrate in figura 4.

Din figura 4 se poate observa că PU-PTHF/MDI/HPC adsoarbe o cantitate semnificativ mai mare de albumină decât de fibrinogen. Putem spune, că proprietăţile de suprafaţă ale materialului studiat sunt selective pentru adsorpţia de albumină, atât în condiţii noncompetitive, cât şi în condiţii competitive. Nu s-au observat diferenţe semnificative ale adsorpţiei celor doua proteine în funcţie de prezenţa sau absenşa proteinei concurente, deşi există o uşoară tendinţă de reducere a cantităţii de proteină adsorbită în condiţii

TABELUL I
Cheagul format prin recalcifierea sângelui integral în prezenţa PU-PTHF/MDI/HPC

Suprafaţa incubată	Greutate cheag (mg)	% de cheag peste cel produs de martorul negativ
Martor negativ (fără polimer)	24,8±2,03	0
PU-PTHF/MDI/HPC	28,4±2,93	14,52
Martor pozitiv (colagen)	42,5±3,50	71,37

competitive, în special pentruu albumină. Aceasta poate fi cauzată de dislocarea albuminei de fibrinogen prin fenomenul Vroman, descris în literatura ca proces de înlocuire a primelor proteine adsorbite, de obicei de dimensiuni mai mici şi aflate în concentraţii mai mari, cu proteine de dimensiuni mai mari, care se gasesc în concentraţii mai mici, dar care pot avea o specificitate mai mare de interacţie cu suprafaţa (21). Având în vedere că rezultatele noastre nu au arătat diferenţe semnificative între albumina adsorbită în soluţie pură şi cea adsorbită în prezenţa fibrinogenului, putem spune că fenomenul Vroman, în cazul celor doua proteine, este slab exprimat, adsorbindu-se preferenţial albumina. Aceste date sunt corelate cu studiile noastre anterioare, care arată ca materialul PU-PTHF/MDI/HPC are o hidrofilie crescută, iar conform mai multor studii bibliografice, această proprietate favorizează adsorbţia albuminei (21,22,23). Astfel, rezultatele noastre au evidenţiat proprietăţi de suprafaţă favorabile unui comportamentul tromborezistent al materialul PU-PTHF/MDI/HPC. Pentru a demonsta acesta afirmaţie, însă, am efectuat testul *in vitro* de formare a cheagului din sângele integral. Rezultatele au fost comparate cu cele obtinute pentru un compus cunoscut pentru proprietăţile sale trombogene – un film de aceleaşi dimensiuni, obtinut din colagen bovin. Rezultatele sunt prezentate in tabelul I.

Din tabelul I se poate observa o diferenţă foarte mică între greutatea cheagului format în contact cu PU-PTHF/MDI/HPC şi cel al martorului negativ, obţinut prin recalcifierea sângelui în absenţa materialului. Având în vedere varianţa standard ale rezultatelor obţinute, diferenţa este la limita semnificaţiei statistice. Comparând rezultatul obţinut cu cele ale martorului pozitiv, se poate observa o diferenţă semnificativă între cele două situaţii, ceea ce ne permite să afirmăm că materialul PU-PTHF/MDI/HPC nu modifică proprietatea de coagulare a sângelui.

CONCLUZII

Membranele poliuretanice obtinute prin metoda de precipitare în apă din PU-PTHF/MDI/HPC sunt membrane bifaciale, având o porozitate şi rugozitate diferită a suprafeţelor. Structura internă a membranei este una poroasa, prezintă o reţea de pori interconectaţi, care din punct de vedere al dimensiunilor, poate permite neovascularizarea sau popularea cu celulele la interactiunea cu tesuturile biologice. Sarcina electrică de suprafaţă a membranelor PU-PTHF/MDI/HPC este una usor pozitivă, aproape neutră, ceea ce descurajează adsorpţia de fibrinogen la concentraţia lui fiziologică atât în condiţii idealizate, noncompetitive, cât şi în condiţii de competiţie cu alte proteine. Datorită proprietăţilor sale hidrofile şi a sarcinii superficiale neutre, membranele PU-PTHF/MDI/HPC favorizează adsorpţia de albumină atât în soluţia fiziologică simplă de albumină cât şi în prezenţa fibrinogenului. În final, studiul a demonstrat că membranele poliuretanice de tip PU-PTHF/MDI/HPC sunt tromborezistente, iar proprietăţile coroborate indică o capacitate crescută pentru biointegrare la condiţiile structurale şi funcţionale ale sistemului cardiovascular.

MULŢUMIRI

Această cercetare a fost realizată cu sprijinul financiar al Programului de Proiecte Interne al Universităţii de Medicină şi Farmacie „Gr.T. Popa" din Iaşi, competiţia 2009.

Aducem mulţumiri colectivului laboratorului LAMINAST al Institutului de Chimie Macromoleculară „P. Poni" din Iaşi (şef laborator CS I, Dr. Aurica P. Chiriac) pentru efectuarea măsurătorilor de potenţial zeta.

MEASUREMENT OF TOTAL ANTIOXIDANT ACTIVITY WITH CHLORPROMAZINE RADICAL CATION (Abstract): In the present study there is described a simple and sensitive method for the evaluation of antioxidant activity in chlorpromazine-Fe (III) system using ascorbic acid as standard. **Material and method**: Chlorpromazine [2-chloro-N-(3-dimethyl-aminopropyl)-phenothiazine] is oxidized in acidic media by Fe (III) with the formation of a stable radical cation characterized by an intense visible absorbtion band (λ = 540 nm). The optimum parameters for the stability of the radical cation have been studied: molar ratio chlorpromazine-Fe (III), pH, solvents. Spectrophotometric methods have been used in these studies. **Results**: The chlorpromazine radical cation is stable in the acidic media (pH = 3) at a molar ratio chlorpromazine : Fe (III) of 2 : 1. Ascorbic acid reduces these radicals and induces a decrease of absorbance. Percent inhibition was calculated and plotted as a function of the concentration of standard antioxidant solutions. The results show that percent inhibition varies in a linear manner with the ascorbic acid concentration. Percent inhibition is higher when the antioxidant solution is added after generation of radical cation. **Conclusions**: It has been developed a method for evaluating antioxidant activity in the chlorpromazine : Fe (III) system using ascorbic acid as a standard. The method is fast, simple and sensitive; it can be applied for the detection and evaluation of the antioxidant activity of simple or complex systems. **Key words:** CHLORPROMAZINE RADICAL CATION, ANTIOXIDANT ACTIVITY, SPECTROPHOTOMETRIC METHODS

Oxidative stress created by in excess production of free radicals is involved in many degenerative diseases: coronary heart disease, stroke, diabetes mellitus, cancer, rheumatism, aging.

Free radicals derived from oxygen (reactive oxygen species – ROS) or nitrogen (reactive nitrogen species – RNS) are unstable, highly reactive and energized molecules having unpaired electrons. They play an important role in cellular injuries and also initiate the peroxidation of polyunsaturated fatty acids in biological membranes (1,2,3,4).

Aerobic organisms are protected from the radicals effects by a natural antioxidant defence system involving enzymatic and non-enzymatic mechanisms.

At the same time, the exogenous antioxidants from fruits and vegetables have protective effects against cell oxidation (5,6,7,8,9).

Different methods for the evaluation of antioxidant activity have been reported. Such methods often use stable free radicals for studying radical scavenging abilities (10,11, 12,13,14).

This study describes a simple and sensitive decolorization assay based on the generation of chromogenic chlorpromazine radical cation and on its scavenging by ascorbic acid.

MATERIAL AND METHOD

The following reagents were used :

- L (+)-ascorbic acid (Merck) as standard antioxidant ; 0.05 M stock solution was prepared in twice-distilled water ; the solution was diluted just before use ;
- iron (III)-chloride hexahydrate puriss. p.a. (Fluka Chemie Buchs), 0.05 M solution ;
- 37% hydrochloric acid (Farmitalia), 0.1 M solution ;
- chlorpromazine maleate, 0.01 M solution ; the solution was prepared in acidulated water, at light heating.

Experiments were performed using a Hewlett Packard 8453 UV–VIS spectrophotometer.

Preparation of chlorpromazine radical cation solution

Chlorpromazine solution (20 mL, 0.01 M) was added to 10 mL of 1.0 M HCl. Chlorpromazine acidic solution was then treated with 5 mL of 0.005 M $FeCl_3$. Radical cation solution had a maximum absorbance at λ = 540 nm and became stable after 10 min.

In order to study antioxidant activity, different volumes of ascorbic acid solution were added ; the final concentration of ascorbic acid in reaction mixture ranged between 0.125 μmol and 0.750 μmol. The absorbance was determined after 10 min.

Percent inhibition was calculated as : % inhibition = $(1-A_s/A_0)$ x 100, where A_0 is the absorbance of the unscavenged radical cation solution and A_s is the absorbance of the sample after the addition of antioxidant solution.

Percent inhibition was plotted as a function of the concentration of standard antioxidant.

RESULTS AND DISCUSSIONS

The most important property of phenothiazine and its derivatives is their susceptibility to oxidation. They are easily oxidized by different chemical, electrochemical, photochemical and enzymatic agents with the formation of a coloured oxidation product-intermediate radical cation (15).

Chlorpromazine reacts with $FeCl_3$ in acidic media yielding a red coloured radical cation as a result of univalent oxidation of phenothiazine ring.

In the present study, this chromogenic reaction was used in order to develop a decolorization assay for the estimation of antioxidant activity of some natural antioxidants. For this purpose, the optimum parameters for the stability of the radical have been studied.

The stability of oxidation products depends on acidity, concentration of oxidizing agents, time, temperature and the presence of some salts.

The stability of the cation radical colour depends mainly on the oxidizing agent. In the case of strong oxidants, the colour of radical disappears quickly due to the second step of reaction which leads to the formation of a colourless sulphoxid.

The effect of different concentrations of an oxidizing agent on the colour intensity and stability of the radical cation was studied (fig. 1). At a molar ratio chlorpromazine : Fe (III) of 2 : 1 the radical is stable for almost 1 h.

We preferred a molar ratio chlorpromazine : Fe (III) of 8 : 1 in order to avoid an excess of Fe (III) which might interfere with the reaction between antioxidant and radi-

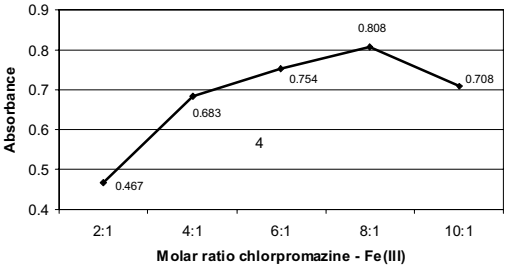

Fig. 1. The influence of molar ratio chlorpromazine : Fe (III) on the stability of the coloured radical cation

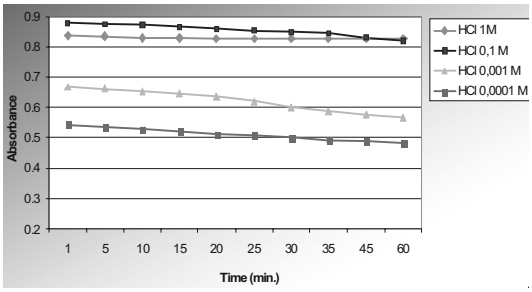

Fig. 2. Time course of chlorpromazine cation formation at different acid strengths (aqueous solutions of 0.001 M–1.0 M HCl)

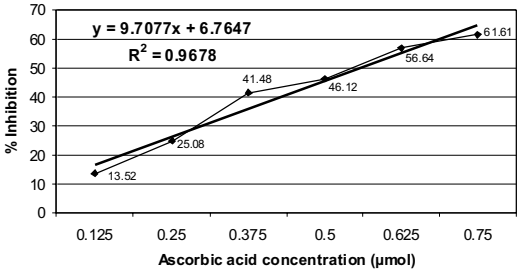

Fig. 3. Effects of ascorbic acid concentration on the inhibition of chlorpromazine radical cation (ascorbic acid was added after generation of chlorpromazine radical cation)

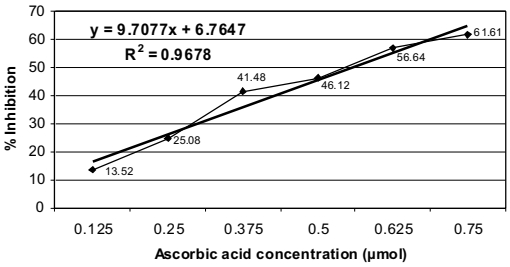

Fig. 4. Effects of ascorbic acid concentration on the inhibition of chlorpromazine radical cation (ascorbic acid was added before generation of chlorpromazine radical cation)

cal cation leading to erroneous results.

The effect of acid strength on the stability of chlorpromazine radical cation was also monitored (fig. 2).

The stability of the radical cation increases in an acid medium.

The inhibition or scavenging of the radical cation by ascorbic acid as standard antioxidant has been studied.

The reaction of ascorbic acid with chlorpromazine radical cation has been found to be fast, sensitive and reproducible.

Percent inhibition was calculated and plotted as a function of the concentration of standard antioxidant solutions in two series of determinations :

- ascorbic acid has been added to reaction mixture after generation of chlorpromazine radical cation (fig. 3) ;
- ascorbic acid has been added to reaction mixture before generation of chlorpromazine radical cation (fig. 4).

The results show that percent inhibition varies in a linear manner in both cases but % inhibition is higher when the antioxidant solution has been added after generation of radical cation.

CONCLUSIONS

The proposed assay for the evaluation of antioxidant activity in the chlorpromazine--Fe (III) system using the ascorbic acid as standard is fast, simple and sensitive ; it can be applied for the detection and evaluation of antioxidant activity of simple or complex systems.

NOUTĂŢI

KERATINA 17 PROMOVEAZĂ PROLIFERAREA EPITELIULUI ŞI CREŞTEREA TUMORALĂ PRIN POLARIZAREA RĂSPUNSULUI IMUN ÎN PIELE

Tumorile cutanate bazocelulare, incluzând carcinomul bazocelular (BCC) şi hamartomul folicular bazocelular, sunt asociate cu un semnal aberant al genelor Hedgehog (Hh) şi, în cazul BCC, cu un set de multiple variante genetice ale keratinei 5 (codificată de gena KRT5) componenta a filamentului de keratina. Autorii au demonstrat că absenţa /lipsa în tumorile cutanate bazocelulare din cauze genetice a keratinei 17 şi deficitul de co-polimerizare cu keratina 5 întârzie in vivo iniţierea şi creşterea hamartoamelor foliculare bazocelulare la şoarecii care exprimă Hh în epiderm. Aceasta întârziere este precedată de reducerea inflamaţiei şi de polarizarea citokinelor inflamatorii de la Th1 si Th17 cu profil dominant spre un profil dominant Th2. Absenţa keratinei 17 atenuează de asemenea hiperplazia şi inflamaţia la modelele cu dermatită acută. Re-expresia keratinei 17 în *Gli2*^{tg} ; keratinocitele *Krt17*$^{-/-}$ induc selecţia Th1 cu rol deja stabilit în BCC. Se pare că keratina 17 are un rol modulator în expresia Hh în tumorile cutanate bazocelulare ceea ce ar putea avea importanţă în înţelegerea evoluţiei tumorilor cutanate, a psoriazisului şi a reparării leziunilor cutanate (DePianto D, Kerns ML, Dlugosz AA, Coulombe PA. Keratin 17 promotes epithelial proliferation and tumor growth by polarizing the immune response in skin. *Nat Gen* 2010 ; 42 : 910–914).

IgE- AND NON-IgE MEDIATED FOOD ALLERGY IN CHILDREN (Abstract**). Aim**: To evaluate a group of children diagnosed with food allergies mediated by IgE or non-IgE mechanisms**. Material and Methods:** This retrospective study was conducted on 132 patients diagnosed with food-associated hives admitted over a 2-year period to the Pediatric Clinic II of the Iasi "St. Maria" Children's Hospital. **Results:** Serum levels of specific IgE were positive in 85 (64.39%) cases for one or more food allergens, while positive values of IgG4 were recorded in 21 (15.9%) cases. The most commonly involved allergens were cow milk, egg white, peanuts, wheat flour and fish, in agreement with data in the literature. Percentage frequency of risk factors for allergic sensitization was: artificial or mixed feeding (68.18%), family history of atopy (53.78%), food diversification before 6 months of age (52.27%), natural feeding for less than 3 months (37.87%), and prolonged antibiotic therapy (23.48%). Polysensitization to food and airborne allergens correlated with respiratory allergic manifestations (asthma and allergic rhinitis), occurring predominantly in the age group over 4 years, while atopic dermatitis was associated with food allergy in children up to 4 years of age. **Conclusions:** This study shows that IgE-mediated food allergies are more common, with a higher frequency in children below 4 years due to the interaction of genetic and environmental factors and immaturity of the immune system in the first years of life.
Keywords: FOOD ALLERGENS, IMMUNE MECHANISMS, IgG4 ANTIBODIES.

The prevalence of allergic diseases has increased in recent decades due to changes in eating behavior, involvement of environmental agents and infectious factors.

The most common cause of sensitization is food-related, the cutaneous, digestive and respiratory allergic manifestations developing concurrently or alternately.

Food allergy is defined as "a phenomenon in which adverse reactions are caused through antigen-specific immunological mechanisms after exposure to given food" (1).

The etiopathogenic factors involved in food allergy and therapeutic possibilities are important research goals.

MATERIAL AND METHODS

This retrospective study was conducted on 132 patients diagnosed with food-associated hives admitted over a 2-year period to the Pediatric Clinic II of the Iasi "St. Maria" Children's Hospital.

Total IgE was measured by ELISA, and the determination of serum specific IgE specific to 20 of the most common food and airborne allergens by CLA System *Quanti Scan* (Innogenetics, Heiden, Germany).

An enzyme immunoassay for the quantitative determination of IgG4 antibodies against 20 food allergens was performed using Fin Test Kit TM IgG4 Screen ELISA 20. The tested allergens were: egg white, cow milk, fish, wheat flour, rye flour, barley flour, orange, banana, kiwi, strawberry, celery, soy, carrot, tomato, hazelnuts, peanuts, curry, pepper, sesame, and pork.

Cutaneous testing was done with skin prick test for 7 food allergens (milk, egg, wheat, hazelnuts, nuts, fish, soy).

Statistical analysis was performed using statistical software SPSS10.0, and data were analyzed using descriptive and inferential statistics (Student t test).

RESULTS

Age group distribution showed that predominantly affected were the children aged under 4 years, 93 (70.45%) cases. The mean age at admission was 30 months.

Percent frequency of risk factors for allergic sensitization was as follows: artificial or mixed feeding (68.18%), family history of atopy (53.78%), food diversification before 6 months of age (52.27%), natural feeding for less than 3 months (37.87%), and prolonged antibiotic therapy (23.48%) (fig.1).

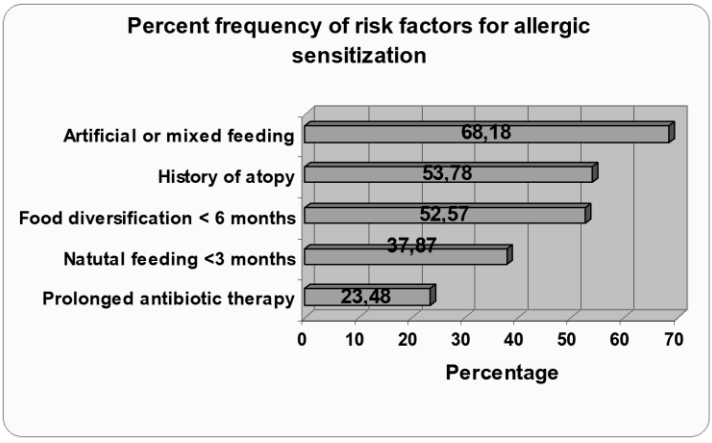

Fig. 1. Hierarchy of risk factors for allergic sensitization

All patients (132) presented hives-like skin manifestations, while associated digestive and respiratory manifestations were present in 18 (13.63%) and 16 (11.36%) cases, respectively.

The associated allergic manifestations were: atopic dermatitis in 22 (16.66%) cases, asthma 11 (8.33%) cases, angioedema 36 (27.27%) and allergic rhinitis in 5 (3.78%) cases.

In 85 (64.39%) cases specific IgE were positive for one or more food allergens. The allergens most commonly involved were: cow milk 28 cases (21.21%, p =

0.000), egg white 19 cases (14.39%, p = 0.000), peanuts 10 cases (7.57%, p = 0,000), fish 8 cases (6%, p = 0.000), soy 6 cases (4.54%, p = 0.000), nuts 6 cases (4.54%, p = 0.000), wheat flour 5 cases (3.78%, p = 0.003), strawberries 2 cases (1.51%, p = 0.011) and rye flour 1 case (0.75%, p = 0.150) .

All allergens were statistically significant except for rye flour (p = 0.150) (fig. 2).

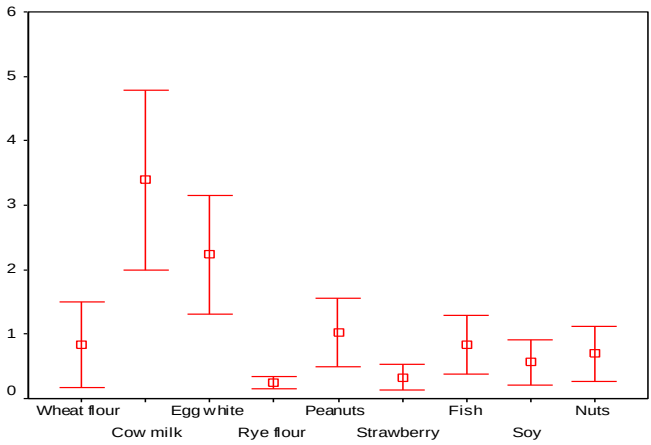

Fig. 2. The most common specific IgE allergens

In patients with low specific IgE levels but in which clinical manifestations and history were suggestive of allergy (47 cases - 35.60%), IgG4 antibodies against 20 food allergens were determined. Of these, 21 (15.9%) cases showed positive IgG4 levels against the following allergens: wheat flour (5 cases, p = 0.049), cow milk (3 cases, p = 0.072), egg white (2 cases, p = 0.061), peanuts (3 cases, p = 0.064), rye flour (2 cases, p = 0.040), strawberries (2 cases, p = 0.108), nuts (2 cases, p = 0.027), fish (1 case, p = 0.006) and soy (1 case, p = 0.087) (fig. 3). One patient presented mixed allergy to peanuts and nuts.

Of these allergens only wheat flour only (p = 0.049), rye flour (p = 0.040) and fish (p = 0.006) were statistically significant.

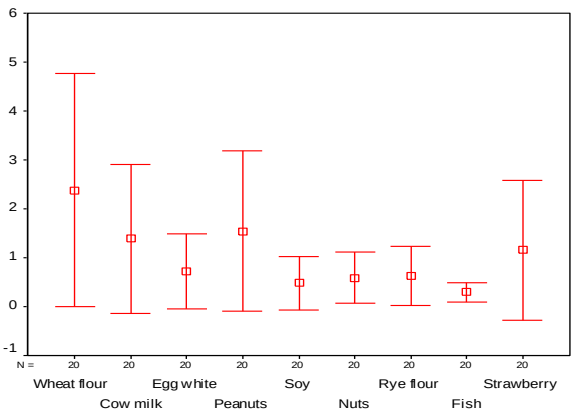

Fig. 3. The most common specific IgG4 allergens

In patients with positive IgG4 levels to different food allergens, 89% presented associated digestive and cutaneous symptoms, suggesting that the level of specific IgG4 antibodies is high in patients with gastrointestinal allergy, but has no predictive value.

Polysensitization to food and airborne allergens correlated with respiratory allergic manifestations (asthma and allergic rhinitis), occurring predominantly in the age group over 4 years, while atopic dermatitis was associated with food allergy in children under 4 years.

The reference values for specific IgG4 antibodies are listed in table I.

TABLE I
Interpretation of results for specific IgG4 antibodies

CLASS	REFERENCE VALUE	INTERPRETATION
0	<0.35 U/mL	**negative-** no IgG4 antibodies detected
1	0.35-0.7 U/mL	**borderline-** low level of IgG4 antibodies
2	0.7-3.5 U/mL	**positive-** moderate level of IgG4 antibodies
3	3.5-17.5 U/mL	**distinctly positive-** high level of antibodies
4	>17.5 U/mL	**Highly positive-** very high levels of IgG4 antibodies

DISCUSSION

Food allergy is defined as an immune response to food proteins affecting approximately 8% of children and 2% of adults (2), but it's the prevalence, as well as that of all allergic diseases is increasing.

In food allergy the mechanisms involved may be IgE or non-IgE mediated immune reactions. The immune mechanisms involved in non-IgE mediated reactions may be based on the participation of subtype 4 IgG antibodies. These types of IgG4 antibody mediated reactions are characterized by less severe and less specific symptoms, and have a late onset after the intake of the incriminated food (up to 72 hours).

There are several arguments supporting the involvement of IgG4 antibodies in non-IgE mediated food allergies: allergic reactions may occur independently of IgE specific antigen; subsequent decline of IgG antibody level when the incriminated food is removed from diet; specific IgG antibodies were identified in celiac disease, atopic eczema and in diseases associated with increased intestinal permeability (chronic inflammatory bowel disease) (3).

Besides hives and anaphylaxis triggered by IgE-mediated immune mechanisms, there are several cell-mediated diseases, such as food protein-induced eosinophilic esophagitis or enterocolitis. Non-IgE mediated food allergies that manifest with food protein-induced entercolitis syndrome or eosinophilic esophagitis are rare and have a favorable course on elimination diet (4).

Immune-mediated food allergies have to be distinguished from food intolerances caused by non-immune mechanism which are non-specific and their symptoms and those of irritable bowel syndrome often overlap (5). Allergic diseases by food sensitization are more common in the early years of life, their frequency decreasing with age, with the acquisition of tolerance

to food. Allergic manifestations with onset in the early years of life are the result of the interaction between genetic factors, environmental factors (artificial feeding, incorrect diversification, prolonged antibiotic therapy) and immaturity of the immune system in early childhood (6).

In our study group the diagnosis of food allergy was based on the criteria in international guidelines, suggestive clinical manifestations, thorough history, and positive levels of serum specific IgE and IgG4 against food allergens, positive skin tests, elimination diet, and oral loading test. The latter must be done under close medical supervision as it can cause such severe adverse reactions as anaphylaxis.

The analysis of specific IgE and IgG4 shows that 64.39% of the cases were IgE-mediated allergies and 15.9% IgG4-mediated allergies. The allergens most frequently involved were cow milk ($p = 0.000$), egg white ($p = 0.000$), peanuts ($p = 0.000$), wheat flour ($p = 0.003$) and fish ($p = 0.000$), in agreement with the data in literature (4, 7, 8). Correlation of skin test with specific IgE level showed a concordance between results. Skin tests have a sensitivity of 95% and a specificity of 50% (9). A negative skin test result has a high predictive value in children older than 1 year, while in children less than 1 year its negative predictive value is lower due to the particularities of cutaneous mast cells (small number and low reactivity). A positive skin test has a positive predictive value of only 50%. If history is not strongly suggestive of an allergy, the diagnosis should be confirmed by a challenge test (10).

With regard to egg allergy, recent studies estimate that it affects approximately 0.5-2.5% of children (11, 12), but there are studies reporting a higher percentage; thus, an Australian study suggests that 8.9% of children have allergic reactions to egg (13). In our study egg allergy is the second most common food allergy. Egg allergy is associated with a high risk of allergy to peanuts or other food allergens, atopic dermatitis, occurrence of respiratory allergy and asthma (14, 15, 16). The rate of resolution of egg allergy is slow; most studies show that tolerance to egg develops at age 3 (17), but there are studies suggesting that about half of children develop tolerance at age 12 (18). The latter study demonstrated persistent egg allergy in 42% of children in their teens, suggesting that the number of adults with egg allergy can increase with time, although current estimate of egg allergy among adults is 0.2% (19).

Factors predictive of the resolution of egg allergy are: initial reaction characteristics (isolated hives/angioedema versus other events), specific IgE level, intensity of skin prick test reaction, severity of atopic dermatitis, IgG4 level, response of interleukin 4 (IL-4). Of these, the first two are the most important predictors for resolution (11).

CONCLUSIONS

This study shows that IgE-mediated food allergies are more common, the highest percentage being recorded in children less than 4 years of age due to the interaction of genetic and environmental factors and immaturity of immune system in the early years.

EVALUAREA COMPARATIVĂ A MODULUI DE ÎNCORPORARE AL UNUI SUPERDEZAGREGANT ANIONIC ASUPRA CALITĂȚII COMPRIMATELOR CU RANITIDINĂ

Liliana Postolache[1], Eliza Gafițanu[2]
1. Doctorand al Universității de Medicină şi Farmacie "Grigore T. Popa" - Iaşi
Universitatea de Medicină şi Farmacie "Grigore T. Popa" - Iaşi
Facultatea de Farmacie
2. Disciplina de Tehnologie Farmaceutică

COMPARATIVE EVALUATION OF THE ANIONIC SUPERDISINTEGRANT INCORPORATION MODE ON THE QUALITY OF RANITIDINE TABLETS (Abstract): The present study was based on the impact of the superdisintegrants incorporation mechanism on the immediate realese of the tablets final performances. The aim was the selection of the working method to obtain Ranitidine 150 mg tablets with the desiderate quality and in reproducible conditions. **Material and methods:** The effect of the incorporation mode of sodium starch glycolate on the aspect, granules size distribution and flowing properties of the lubricated product, and also the weight uniformity, hardness, disintegration, friability, and dissolution of the Ranitidine 150 mg tablets prepared by dry granulation was studied. The addition mode of the disintegrant was realized in three ways: intragranular, extragranular, and distributed equally between the two phases. The distribution range for the tablets weight was established. Relative standard distribution was calculed for the weight and hardness of the uncoated tablets. **Results:** The powder flow and, implicit, the weight uniformity of the uncoated tablets was positive influenced by the extragranular incorporation of the superdisintegrant. The disintegration time was identical for all the three disintegrant addition modes, and the hardness and the friability were not significantly influenced by working method, the obtained values were similar. For the developed formulations, the percent of the ranitidine dissolution was high, but higher in the extragranular incorporation. **Conclusions:** For the product quality the extragranular addition mode seemed the best method to incorporate the superdisintegrant. **Key words:** DRY GRANULATION, SUPERDISINTEGRANTS, INTRAGRANULAR INCORPORATION, EXTRAGRANULAR INCORPORATION, DISSOLUTION.

Eficacitatea terapeutică a unui medicament este dependentă de capacitatea sa de a elibera principiul activ, astfel încât acesta să poată fi absorbit de către membranele biologice. Prin urmare, în formularea comprimatelor cu eliberare imediată, se urmăreşte realizarea unui compromis între obținerea unor produse cu dezagregare şi dizolvare rapidă şi procesul de fabricație al unui produs cu rezistență mecanică la manipulare. Facilitarea dizolvării se realizează prin adăugarea superdezagreganților. Aceştia influențează atât viteza şi timpul de dizolvare, cât şi caracteristicile fizice ale comprimatelor, cum ar fi rezistența mecanică şi friabilitatea (1, 2, 3, 4).

MATERIAL ŞI METODE

Pentru realizarea studiilor s-au utilizat trei serii de comprimate filmate cu 150 mg ranitidină, obţinute prin granulare uscată, conform aceleiaşi formule de fabricaţie, dar cu mod diferit de încorporare al superdezagregantului (tab. I).

Celuloza microcristalină tip 102 a avut rol de diluant al substanţei active şi liant. Ca dezagregant s-a lucrat cu amidon glicolatul de sodiu, iar drept glisant s-a utilizat dioxidul de coloidal. Lubrifierea a fost realizată cu stearat de magneziu, iar acoperirea comprimatelor s-a efectuat prin filmarea cu un produs pe bază de alcool polivinilic - Opadry yellow sub formă de soluţie apoasă 16,7 %.

Amestecurile omogene, rezultate prin diluarea principiului activ cu / fără amidon glicolat de sodiu şi celuloză microcristalină 102 pe un omogenizator în V (15 minute la 7 rpm), s-au granulat pe un compactor Alexanderwerk WP 50N/75 (presiunea de compactare de 25 bari, sita de 1,25 mm), în condiţii similare de funcţionare a echipamentului. Lubrifierea, realizată pe omogenizatorul în V, s-a efectuat prin omogenizarea granulatului cu / fără amidon glicolat de sodiu, dioxid de siliciu coloidal (5 minute la 7 rpm) şi stearat de magneziu (3 minute la 7 rpm). Comprimatele biconvexe cu diametrul de 9 mm şi masa de 300 mg s-au obţinut pe un echipament Kilian S 250 (forţa de comprimare 15 kN, viteza de 25 rpm), filmarea lor efectuându-se într-un echipament Driacoater.

TABELUL I

Compoziţia calitativă a comprimatelor filmate

Materia primă	RA1 %(m/m)	RA2 %(m/m)	RA3 %(m/m)
Clorhidrat de ranitidină	53,85	53,85	53,85
Celuloză microcristalină 102	39,42	39,42	39,42
Amidon glicolat de sodiu intragranular	0,96	-	0,48
Amidon glicolat de sodiu extragranular	-	0,96	0,48
Dioxid de siliciu coloidal	0,96	0,96	0,96
Stearat de magneziu	0,96	0,96	0,96
Opadry yellow	3,85	3,85	3,85

Deoarece curgerea pulberilor omogene este importantă pentru uniformitatea masei comprimatelor, înainte de începerea etapei de comprimare a fost studiat comportamentul la curgere al produselor lubrifiate. S-au determinat: densitatea iniţială şi tasată, indicele Haussner şi Carr, aspectul şi distribuţia granulometrică. Comprimatele neacoperite au fost studiate comparativ din punct de vedere al uniformităţii masei, rezistenţei mecanice, friabilităţii, timpului de dezagregare. Pentru comprimatele filmate s-a determinat procentul de ranitidină dizolvată în 45 minute.

Aparatele utilizate au fost: microscop AxioScope A_1 cu o magnitudine de 50x - *aspectul granulatelor lubrifiate*, sortator Eweka cu şase tipuri de site (1000 μm, 500μm, 250 μm, 180 μm, 125 μm, 90 μm, 63 μm, 45 μm) - *granulometria*, aparat de măsură a densităţii tasate Electrolab ETD 1020 (cilindrul de 100 ml, înălţimea de tasare de 14 mm ± 2 mm, frecvenţa tasărilor de 300/minut, testele finalizându-se la

1250 tasări) - *densitatea şi indicii de curgere Haussner I_H şi Carr I_C,* balanţă analitică Mettler Toledo ABS - *masa medie şi uniformitatea masei comprimatelor,* tester 6D Dr. Schleuniger PHARMATRON - *rezistenţa mecanică,* tester Hanson Reserch QC 21 - *timpul de dezagregare,* friabilator tip Vankel AG 104 – *friabilitatea comprimatelor,* spectrofotometru Carry 50 – *procentul de ranitidină dizolvată.*

S-a calculat masa medie a procesului de comprimare (media maselor medii ale eşantioanelor), deviaţia standard SD a procesului (media deviaţiilor standard ale eşantioanelor) şi deviaţia standard relativă RSD a procesului (media deviaţiilor standard relative ale eşantioanelor). Pentru toate eşantioanele s-a calculat distribuţia procentuală a valorilor maselor individuale faţă de masa medie a eşantionului (încadrarea valorilor individuale).

Parametrii rezistenţă mecanică, dezagregare, friabilitate şi dizolvare s-au stabilit respectând prevederile *Farmacopeii Europene* 6.0 (5).

Determinarea procentului de ranitidină dizolvată după 45 minute s-a realizat prin metoda spectrofotometrică folosind ca mediu de dizolvare apa distilată la o temperatură de 37°± 0,5°C, la o viteză de rotaţie a paletelor de 50 rpm. S-a determinat absorbanţa soluţiei de referinţă şi probă la lungimea de undă de 314 nm în cuve de un cm grosime folosind apa distilată ca lichid de compensaţie. Testul s-a efectuat pe şase comprimate şi s-a calculat media procentelor de ranitidină dizolvată.

REZULTATE

Analiza distribuţiei granulometrice nu a arătat diferenţe semnificative între cele trei serii de produse lubrifiate, dimensiunea medie a particulelor având valori apropiate (fig.1).

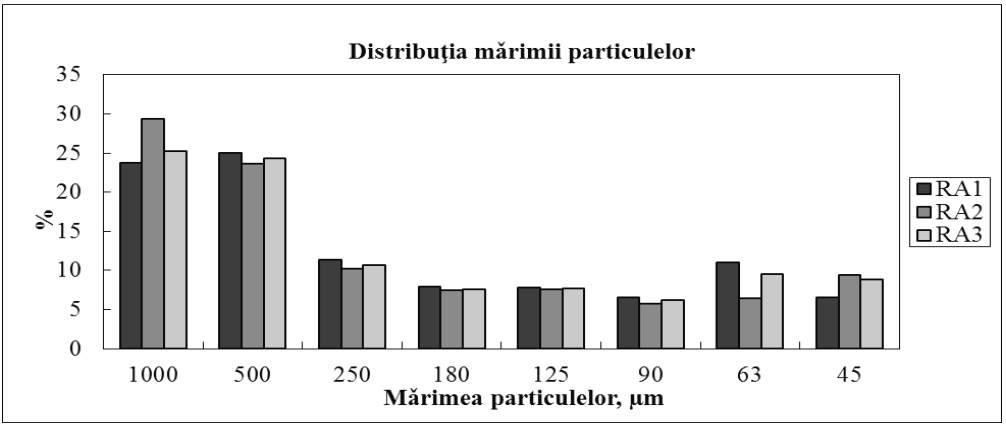

Fig. 1. Reprezentarea grafică a distribuţiei mărimii particulelor

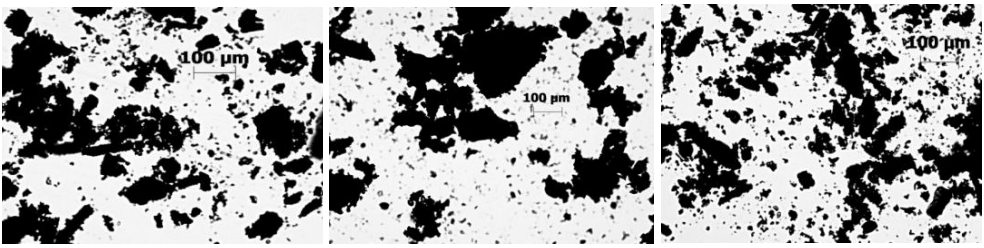
Valorile pentru densitatea produselor tasate au variat în succesiunea RA1> RA3>RA2, adăugarea superdezagregantului în etapa de lubrifiere determinând o tasare superioară a produsului. Corelaţia indice Haussner – indice Carr a arătat o curgere bună pentru RA2: $I_H < 1,25$ respectiv 1,239 şi $I_C < 20\%$, respectiv 19,277 (6). Seriile RA1 şi RA3 au prezentat o curgere mai slabă, dar suficientă pentru încadrarea masei comprimatelor în limitele de admisibilitate stabilite (tab. II).

TABELUL II

Determinarea factorilor de curgere pentru produsele lubrifiate

Parametrii analizați	RA1	RA2	RA3
Densitatea produsului netasat do (g/ml)	0,574	0,602	0,588
Densitatea produsului tasat df (g/ml)	0,781	0,746	0,763
Indicele Haussner I_H	1,359	1,239	1,297
Indicele Carr I_C (%)	26,437	19,277	22,935

Vizualizarea aspectului particulelor nu a evidențiat diferențe mari între cele trei serii de produs. S-a sesizat procentul mai mare de pulbere fină în cazul RA3 (fig.2).



(a) (b) (c)

Fig. 2. Aspectul particulelor lubrifiate de RA1 (a), RA2 (b), RA3 (c)

TABELUL III

Caracteristicile fizico chimice ale comprimatelor preparate

Parametri analizați	RA1	RA2	RA3
Masă medie comprimate (g)	0,30147	0,30042	0,30011
SD proces de comprimare (g)	0,0047	0,0006	0,0030
RSD proces comprimare (%)	1,55	0,19	1,02
distribuție masă comprimate (%)	-3,54 / +3,29	-0,41 / +0,59	-1,94 / +2,66
RSD rezistență la rupere (%)	1,82	1,02	1,56
timp dezagregare (min)	10	10	10
friabilitate (%)	0,29	0,13	0,20
ranitidină dizolvată (%)	94,86	99,80	98,10

Masa medie şi valorile maselor individuale ale comprimatelor neacoperite s-au plasat în intervalul 300 mg ± 3,5%. Rezistența mecanică (168 – 180 N) şi friabilitatea (0,13 – 0,29%) au fost satisfăcătoare, asigurând filmarea, ambalarea şi utilizarea comprimatelor. Dizolvarea ranitidinei s-a realizat în procente ridicate de peste 90% (tab. III).

DISCUȚII

Dintre caracteristicile produselor lubrifiate corespunzătoare celor trei formulări, modul de încorporare al superdezagregantului a influențat uşor numai comportamentul la curgere. Asocierea amidon glicolat de sodiu, dioxid de siliciu coloidal şi stearat de magneziu din etapa de lubrifiere a produsului RA2 a fost benefică proprietăților de curgere ale acestuia.

Uniformitatea masei comprimatelor neacoperite a fost favorizată de adiția extragranulară a superdezagregantului, dispersia datelor fiind mult mai redusă pentru RA2. Valoarea RSD foarte mică pentru RA2 s-ar explica prin curgerea superioară a produsului, lucru ce a permis reglarea mult mai bună a înălțimii camerei de comprimare.

Rezistența mecanică şi friabilitatea comprimatelor nu au fost influențate în mod semnificativ de modul de încorporare al dezagregantului. Timpul de dezagregare realizat a fost identic şi mare pentru toate cele trei tipuri de comprimate, fapt care s-ar putea datora solubilității ridicate în apă a clorhidratului de ranitidină. Fiind componenta majoritară din formularea comprimatelor, solubilitatea sa a influențat atât viteza cât şi mecanismul de dezagregare al comprimatelor. Rezultatele sunt în concordanță cu datele din literatură (2).

Adiția extragarnulară a asigurat de asemenea cea mai buna friabilitate şi dizolvare a comprimatelor. Variabilitatea existentă între cele trei formulări s-a putut explica prin interacțiunea ionică existentă între superdezagregantul anionic şi clorhidratul de ranitidină care este un cation. Date similare referitoare la întârzierea eliberării substanței active în cazul interacțiunii ionice apar şi în literatură (2, 3).

CONCLUZII

În formulările studiate, modul de încorporare al superdezagregantului nu a generat diferențe semnificative între caracteristicile comprimatelor. În toate cazurile s-au obținut comprimate cu rezistență mecanică bună, friabilitate scăzută şi o dizolvare rapidă a substanței active. Totuşi încorporarea extra-granulară a amidon glicolatului de sodiu a condus la comprimate cu o foarte bună uniformitate a masei.

Rezultatele studiului prezintă importanță pentru stabilirea modului de încorporare a superdezagregantului în formularea medicamentelor generice cu ranitidină, când există obligativitatea realizării unui medicament bioechivalent, cu un profil de dizolvare comparativ cu al medicamentului de referință.

EVALUAREA SEMICANTITATIVĂ A METADONEI PRIN METODA CROMATOGRAFIEI ÎN STRAT SUBȚIRE (CSS)

Anne Marie Ciobanu[1], Daniela Baconi[2], Maria Bârcă[1], Claudia Guţu[2], D. Bălălău[2]
Universitatea de Medicină şi Farmacie „Carol Davila" Bucureşti
Facultatea de Farmacie
1. Disciplina Controlul Medicamentului
2. Disciplina Toxicologie

SEMI-QUANTITATIVE DETERMINATION OF METHADONE BY TLC (Abstract): Methadone is the main therapeutic option in heroin addiction treatment, but also an abuse substance. Given the analytical focus on the diagnosis of drug abuse and the usefulness of toxicological analysis methods in both overdose and monitoring substitution therapy, this study was aimed at the semi-quantitative determination of methadone by using Thin Layer Chromatography (TLC). By having the advantage of simplicity and rapidity, TLC finds its rightful place among the analysis methods when other relatively costly methods that involve instrumental performance are not available. **Materials and methods**: TLC plates (silicagel GF 254 Merck), developing system methanol:strong ammonia 100: 1,5, photometric quantification at 254 nm, using TLC Scanner 3 (Camag). **Results**: The results show that methadone can be determined semi-quantitatively in the chromatographic conditions mentioned in the two domains tested (5 – 40 μg and 10 – 80 μg), with the best results obtained in the 5 - 40 μg domain. **Conclusions**: Semi-quantitative TLC evaluation proposed by us has as main advantages the rapidity, simplicity and relatively low cost compared to other useful methods.
Key words: METHADONE, TLC, SEMI-QUANTITATIVE DETERMINATION

Metadona reprezintă principala opţiune terapeutică în cazul dependenţei de heroină. Ea se regaseşte însă şi în categoria substanţelor de abuz (1, 2).

În cursul tratamentului de substituţie cu metadonă, unii heroinomani pot avea recăderi. Deoarece menţinerea în programele de substituţie pe metadonă este condiţionată de abstinenţa de heroină sau alte opiacee, este esenţial să se testeze extraconsumul de opiacee.

Metodele cromatografice au o buna aplicabilitate în studiul analitico-toxicologic al substanţelor de abuz, îndeosebi în analiza pe probe biologice.

Deşi este o metodă mai puţin precisă decât cele trei metode recomandate de grupul de experti OMS (imunoanaliza, HPLC, GC-MS), metoda cromatografiei în strat subţire (CSS) îşi găseşte locul binemeritat printre metodele de analiză, atunci când nu se dispune de aparatura relativ costisitoare pe care o implică metodele instrumentale performante (3, 4). Dată fiind variabilitatea datelor şi a metodelor prezentate în literatură, ne-am propus aplicarea CSS pentru determinarea semicantitativă a metadonei la cantităţi de ordinul microgramelor-zecilor de micrograme (5, 6).

MATERIAL ŞI METODĂ

- Clorhidrat de metadonă s.r., Alcool metilic, Amoniac, Cloroform;
- Plăci de sticlă CSS Merck, gata preparate (silicagel 60 GF 254);
- Cuve de developare;
- Sistem Camag TLC Scanner 3 de achiziţie şi prelucrare a cromatoplăcilor, prevăzut cu cameră obscură, lămpi UV şi cuplat la calculator (soft WinCATS);
- Sistem semiautomat Camag Linomat 5 pentru spotarea probelor pe cromatoplacă;
- Aparat foto pentru captarea imaginilor;
- Balanţă Sartorius.

S-a preparat o soluţie stoc de clorhidrat de metadonă în cloroform de concentraţie 0,2% (2 mg/ml). Din această soluţie, am spotat cu sistemul Camag Linomat 5, cantităti diferite astfel încât să putem obţine o curbă de etalonare. Am testat două domenii de cantităţi: 5 – 40 µg şi 10 – 80 µg.

Developarea s-a realizat în sistemul metanol: amoniac 100:1.5, iar după migrare plăcile au fost examinate la lampa UV (254 nm). Cromatoplăcile au fost prelucrate cu ajutorul sistemului Camag TLC Scanner 3 (densitometru), prevăzut cu cameră obscură, lămpi UV şi cuplat la calculator.

REZULTATE ŞI DISCUŢII

După developarea în sistemul de solvenţi metanol: amoniac 100:1.5, examinarea cromatoplăcilor la lampa UV evidenţiază spoturile corespunzătoare metadonei, având fluorescenţă violetă. În sistemul de solvenţi menţionat, metadona este caracterizată de o valoare R_f de 0,5 (fig. 1 şi fig. 2).

Cu ajutorul sistemului TLC Scanner 3 au fost înregistrate densitogramele metadonei pe cele două domenii testate: 5 - 40 µg (fig. 3) şi respectiv, 10 - 80 µg (fig. 4). Datele obţinute prin cuantificarea fotometrică la 254 nm, au fost utilizate pentru trasarea dreptelor reprezentând variaţia ariei de sub curbă în funcţie de cantitatea de clorhidrat de metadonă (fig. 5, fig. 6).

Evaluarea semicantitativă a metadonei prin CSS se poate realiza utilizând următoarele condiţii experimentale: plăci TLC (silicagel GF 254 Merck), sistem de developare metanol: amoniac 100: 1,5 (R_f = 0,5), cuantificare fotometrică la 254 nm, prin scanarea plăcilor cromatografice cu un sistem Camag TLC Scanner 3 şi prelucrarea datelor cu ajutorul softului WinCATS şi a programului Microsoft Office Excel 2003.

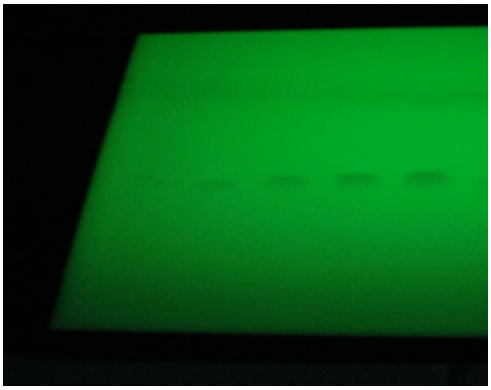

Fig. 1. Analiza CSS metadonei în sistemul de solvenţi metanol: amoniac 100:1.5, domeniul 5 – 40 µg

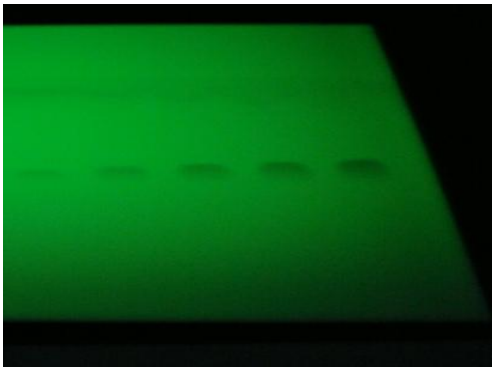

Fig. 2. Analiza CSS în sistemul de solvenţi metanol: amoniac 100:1.5, domeniul 10 – 80 µg

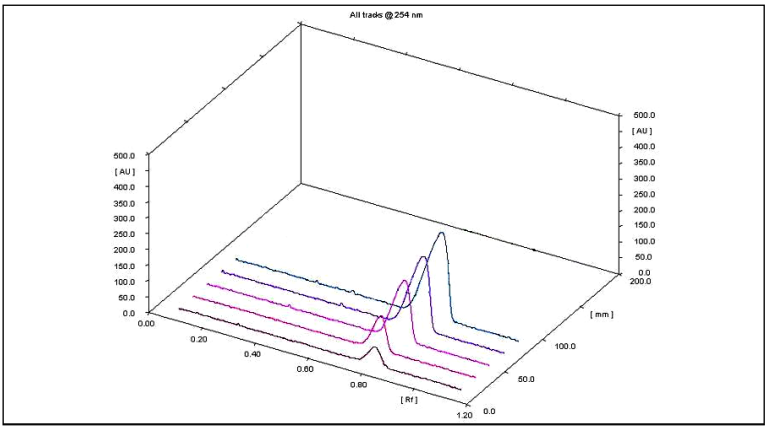

Fig. 3. Densitograma obţinută la evaluarea semicantitativă a metadonei în domeniul de concentraţii 5 – 40 µg/ml

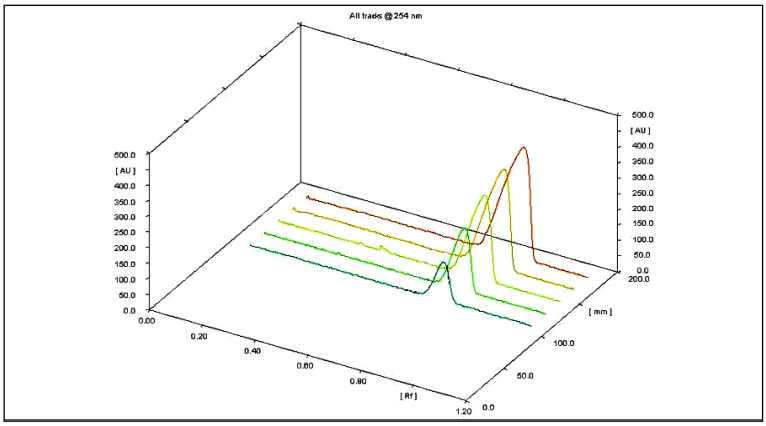

Fig. 4. Densitograma obţinută la evaluarea semicantitativă a metadonei în domeniul de concentraţii 10 – 80 µg/ml

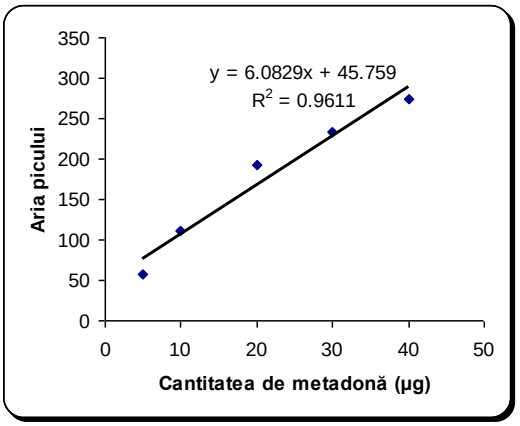

Fig. 5. Dreapta de regresie obţinută la determinarea semicantitativă a clorhidratului de metadonă în domeniul 5 – 40 µg

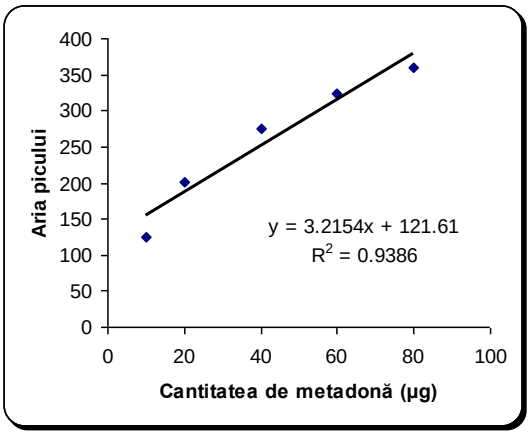

Fig. 6. Dreapta de regresie obţinută la determinarea semicantitativă a clorhidratului de metadonă în domeniul 10 – 80 µg

CONCLUZII

S-a demonstrat că metadona poate fi determinată semicantitativ în condiţiile cromatografice şi în domeniile testate, cu rezultate mai bune pe domeniul 5 - 40 µg.

Metoda de evaluare semicantitativă propusă de noi are ca principale avantaje rapiditatea, simplitatea şi costul relativ scăzut faţă de alte metode mai performante.

Disciplina Chimia mediului şi alimentului

NITRATES AND NITRITES IN MEAT PRODUCTS – NITROSAMINES PRECURSORS (Abstract). **Aim:** To determine the content in nitrates and nitrites and the formation of two nitrosamines (*N*-nitrosodimethylamine – NDMA, and *N*-nitrosodiethylaamine- NDEA) in samples of chicken ham, dry Banat salami, dry French salami, traditional Romania sausages, and pork pastrami. **Material and methods:** Nitrites were determined by spectrophotometry with Peter-Griess reagent, and nitrates by the same method after reduction to nitrites with cadmium powder. High performance liquid chromatography with UV detection was used to determine nitrosamines. **Results:** The initial concentration of nitrates, nitrites, NDMA and NDEA in the samples ranged as follows: 14.10 – 60.40 mg NO_3/kg, 2.70 – 26.70 mg NO_2/kg, from non-detectable to 0.90 μg NDMA/kg, and from non-detectable to 0.27 μg NDEA/kg, respectively. After 28 days the concentrations were: 3.24 – 17.1 mg NO_3/kg, 0.04 – 1.87 mg NO_2/kg, 0.8-29 μg NDMA/kg, and 11.6 – 61.9 μg NDEA/kg, respectively. **Conclusions:** The decreased nitrate and nitrite and increased NDMA and NDEA concentrations prove that in food products nitrosamines are formed due to residual nitrite during their preservation. The determination of nitrasamines revealed levels much above the admitted maximal concentration for these food products. **Key words:** NITRATES, NITRITES, NITROSAMINES, MEAT PRODUCTS

Expunerea la nitrații şi nitriții din surse alimentare şi elemente de mediu reprezintă un risc major pentru sănătatea umană. Nitritul rezidual din produsele alimentare în care nitrații şi nitriții au fost adăugați drept conservanți pot forma în aliment sau în organismul consumatorului nitrozamine, compuşi clasificați de IARC International Agency for Research on Cancer (1) cancerigeni pentru om. Formarea nitrozaminelor în preparatele din carne este un proces complex, influențat de o serie de factori: cantitatea de nitriți respectiv nitrați adăugați inițial, concentrația nitritului rezidual, interacțiunea cu alți aditivi, natura procesului culinar, temperatura şi durata acestuia, condițiile de păstrare a alimentului (2). Mecanismul probabil al formării *in vivo* a dimetilnitrozaminei, una dintre cele mai frecvent întâlnite nitrozamine (2), la nivel gastric, este prezentat în figura 1.

Formarea nitrozaminelor în produsul alimentar are loc lent, progresiv, în funcție de nivelul nitritului rezidual şi de condițiile din mediul de reacție.

Determinarea nitrozaminelor în prepara-

te din carne se poate face prin diverse metode. În prezent sunt utilizate metodele HPLC cu detecţie prin fluorescenţă (3), HPLC cu fotohidroliză post-coloană şi detecţie UV-VIS (4) şi metodele gaz cromatografice (5).

Fig. 1. Mecanismul formării nitrozodimetilaminei (NDMA)

Cercetările efectuate au urmărit determinarea în dinamică a concentraţiilor nitraţilor, nitriţilor, nitrozodimetialaminei şi nitrozodietilaminei din preparate din carne, pe o perioadă de 28 de zile.

MATERIAL ŞI METODĂ

Reactivi

Toţi reactivii utilizaţi la realizarea cercetărilor au fost de puritate analitică şi au foat achiziţionaţi de la compania Fluka Chemika. Pentru determinările HPLC s-au folosit reactivi de puritate corespunzătoare achiziţionaţi de la Fisher Chemicals.

Aparatură

- spectrofotometru JASCO, model V-550 UV-VIS;
- sistem HPLC Shimadzu, detector UV.

Probe de analizat

Analiza în dinamică a conţinutului în nitraţi, nitriţi şi evidenţierea formării a două dintre nitrozamine (NDMA şi NDEA) au fost realizate pe probe de preparate din carne (şuncă de pui, salam bănăţean uscat, salam franţuzesc uscat, cârnaţi tradiţionali şi pastramă de porc), procurate direct de la producător, în prima zi în care puteau fi comercializate. Determinările s-au efectuat iniţial şi la intervale de 7 zile, timp de 28 de zile.

Metode

a) Determinarea nitriţilor

Determinarea conţinutului în nitriţi s-a realizat prin metoda spectrofotometrică cu reactiv Peter - Griess, după separarea acestora din probe prin extracţie în soluţie apoasă (6).

b) Determinarea nitraţilor

Determinarea nitraţilor s-a realizat prin aceeaşi metodă, după reducerea nitratului la nitrit cu pulbere de cadmiu (6). Calcularea conţinutului de nitrat s-a realizat prin diferenţa între nitritul total (după reducerea cu cadmiu) şi nitritul iniţial, determinat în acelaşi extract.

c) Separarea nitrozaminelor

Separarea nitrozaminelor din probele de analizat s-a realizat prin extracţie în tampon fosfat – citrat de pH 6,5 şi acid ascorbic. Purificarea extractelor s-a făcut

prin filtrare prin coloane de Celite 545. Eluatele au fost extrase cantitativ cu diclormetan. Faza organică s-a evaporat la sec la rotavapor şi a servit determinării prin cromatografie de lichide de înaltă performanță a nitrozodimetilaminei şi a nitrozodietilaminei.

d) Determinarea nitrozaminelor

Determinarea nitrozaminelor s-a realizat prin cromatografie de lichide de înaltă performanță; reziduul obținut în urma evaporării s-a reluat cu 1 ml de fază mobilă, acetonitril- acid acetic 1% (20:80 v/v) şi un volum de 20 µl a fost injectat în lichid cromatograf.

e) Condiții de cromatografiere

Instrument: sistem HPLC Shimadzu

Coloana: Grace 25 ×4,6 mm, 5 µm, ODS

Faza mobilă: acetonitril - acid acetic 1% (20:80, v/v)

Debit: 0,8 ml / minut

Volum injectare: 20 µl

Temperatura coloanei: 25°C

Detectia : UV (230 nm)

Timp de retenție NDMA: 4,56 min.

Timp de retenție NDEA: 9,11 min.

Timp de analiză / probă : 10 minute.

Curbele de etalonare pentru nitrit, nitrat, nitrozodimetilamină (NDMA), respectiv nitrozodietilamină (NDEA), sunt redate în figurile 2, 3 şi 4.

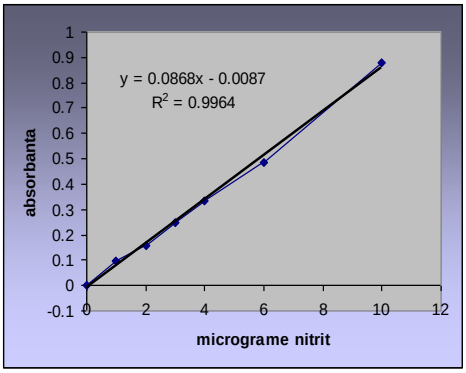

Fig. 2. Curba de etalonare pentru determinarea nitriților

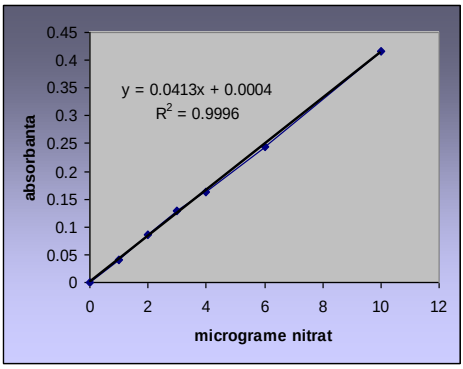

Fig. 3. Curba de etalonare pentru determinarea nitraților

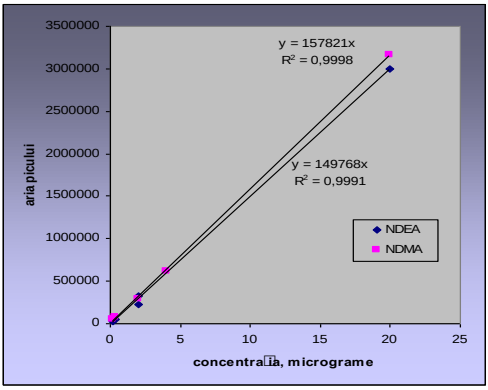

Fig. 4. Curbele de etalonare pentru determinarea NDMA şi NDEA

REZULTATE

Rezultatele obţinute la determinarea nitraţilor, nitriţilor, NDMA şi NDEA sunt redate în figurile 5, 6, 7, 8, 9.

DISCUŢII

Aşa cum era de aşteptat, pe perioada celor 28 de zile de experiment s-a constatat o scădere a concentraţiilor de nitraţi şi de nitriţi din probele analizate iniţial.

Preparatele tip jambon (şunca de pui-proba 1, respectiv pastrama de porc-proba 5) au un conţinut ridicat de nitrit (26,70 mg/kg, respectiv 25,82 mg/kg), fără a depăşi concentraţia maximă admisă pentru acet tip de preparate, de 100 mg/kg. Pe durata studiului concentraţia în nitrit rezidual a probelor scade marcant la toate preparatele analizate într-un procent de 96,17%.

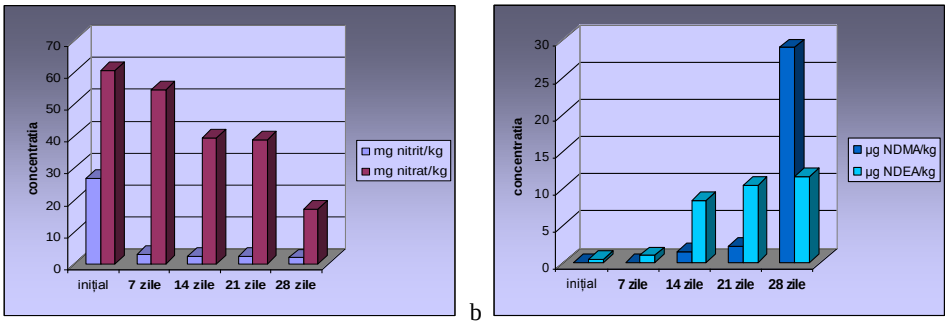

Fig. 5. Concentraţia nitriţilor şi nitraţilor (a), NDMA şi NDEA (b) în proba de şuncă de pui

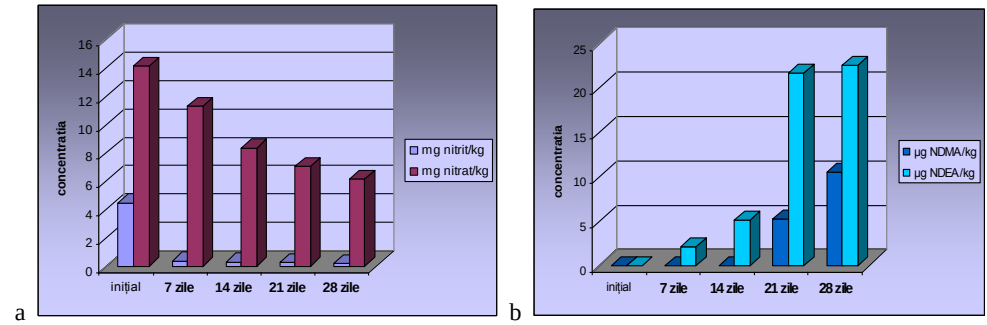

Fig. 6. Concentraţia nitriţilor şi nitraţilor (a), NDMA şi NDEA (b) în proba de salam bănăţean uscat

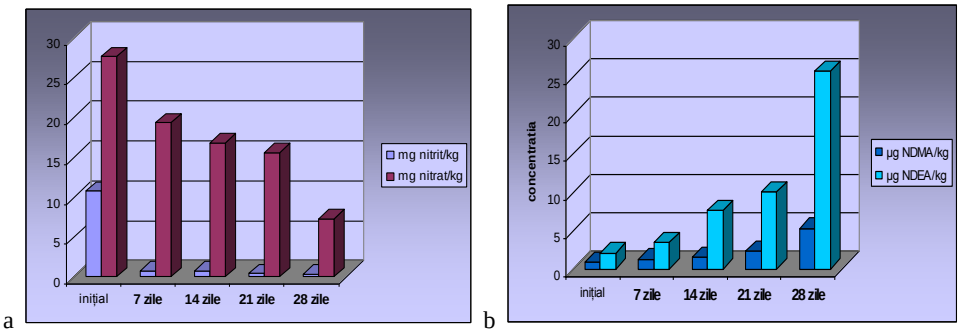

Fig. 7. Concentraţia nitriţilor şi nitraţilor (a), NDMA şi NDEA (b) în proba de salam franţuzesc uscat

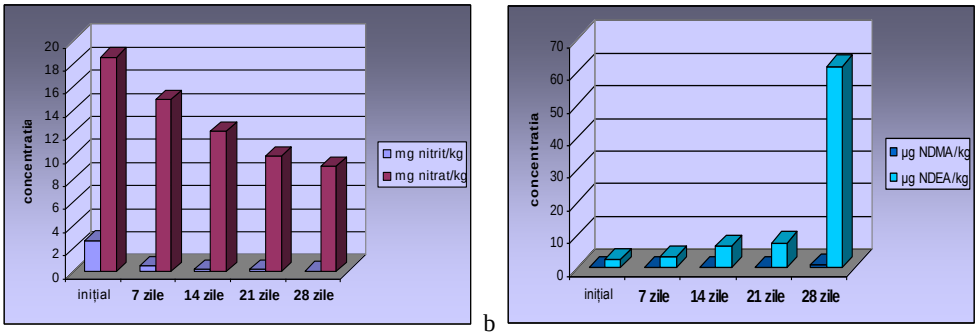
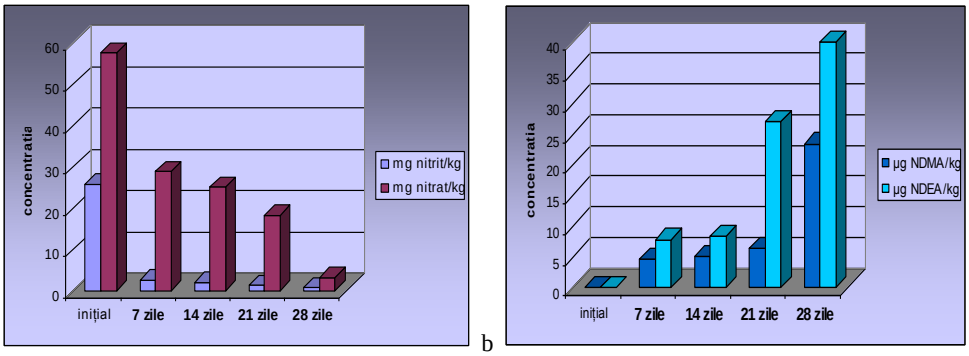


a b

Fig. 8. Concentrația nitriților şi nitraților (a), NDMA şi NDEA (b) în proba de cârnați tradiționali



a b

Fig. 9. Concentrația nitriților şi nitraților (a), NDMA şi NDEA (b) în proba de pastramă de porc

Cantități crescute de nitrați au fost determinate în preparatele tip jambon (probele 1 şi 5), dar şi în proba 3-salam franțuzesc uscat (produs fiert, dublu afumat şi uscat). Pe durata studiului concentrațiile în nitrat au scăzut la toate probele, într-un procent.de 58,14%. Scăderea semnificativă a cantității de nitrat rezidual, în procent de 80 %, s-a observat în ultimul interval de 7 zile a studiului pentru trei din cele cinci probe analizate (probele 1, 3 şi 5).

În ceea ce priveşte prezența nitrozaminelor şi evoluția în dinamică a concentrațiilor acestora, s-a constatat că numai în proba 3–salam franțuzesc uscat, NDMA a fost prezentă inițial într-o cantitate de 0,9 µg/kg. Aceasta ar putea fi explicată prin existența perioadei de maturare a produsului, care în acest caz, a fost de 45 de zile. Pentru celelalte probe conținutul în NDMA a fost sub limita de detecție a metodei HPLC aplicate.

După 7 zile NDMA a fost detectată în proba 5–pastramă de porc, după 14 zile s-a evidențiat în proba 1-şuncă de pui şi după 21 de zile s-a evidențiat în proba 2–salam bănățean uscat; formarea NDMA a avut loc cel mai lent şi în cantitatea cea mai mică (0,8 µg/kg) în proba 4–cârnați tradiționali.

La finalul studiului, probele cu concentrația cea mai mare de NDMA au fost preparatele din carne de tip jambon (proba 1-şuncă de pui şi proba 5- pastramă de porc) – 29 µg/kg, respectiv 23,4 µg/kg.

Remarcăm o proporționalitate directă între conținutul inițial în nitrați şi nitriți şi intensitatea procesului de formare a NDMA; astfel proba 1 a avut inițial o concentrație de 26,7 mg NO_2^-/kg, respectiv 60,4 mg NO_3^-/kg, iar în proba 5 s-a determinat o concentrație de 25,82 mg NO_2^-/kg, respectiv 57, 56 mg NO_3^-/kg. Concentrații-

le de NDMA, respectiv NDEA din probele menţionate au fost, la finalul studiului, de 29 µg NDMA/kg şi 11,6 µg NDEA/kg în proba 1, respectiv de 23.4 µg NDMA/kg şi 40 µg NDEA/kg în proba 5.

Nitrozodietilamina (NDEA) nu a fost evidenţiată la începutul studiului în proba 2-salam bănăţean uscat şi în proba 5-pastramă de porc, în timp ce proba 4-cârnaţi tradiţionali a avut cea mai mare concentraţie -2,7 µg NDEA/kg; după 7 zile în proba 5 s-a determinat cea mai mare cantitate de NDEA, 7,8 µg/kg; la finalul studiului concentraţia de NDEA a crescut semnificativ, atingând valori de 22,5 µg/kg (în proba 2), 25,7 µg/kg (în proba 3), 40 µg/kg (în proba 5), respectiv 61,9 µg/kg (în proba 4).

Rezultatele obţinute sunt în concordanţă ce cele obţinute de alţi autori; astfel în probe de carne şi preparate din carne concentraţia de NDMA a fost între 0,16-1,44 µg/kg, iar concentraţia de NDEA a fost între 0–0,69 µg/kg (2, 7, 8, 9).

CONCLUZII

Cercetările efectuate au scos în evidenţă faptul că nitraţii şi nitriţii adăugaţi în preparatele din carne ca şi conservanţi sunt prezenţi în aliment şi după o perioadă mare de păstrare a acestuia (în concentraţii mai mici decât cele permise de legislaţie) şi pot explica formarea în timp şi creşterea concentraţiei nitrozaminelor în preparatele din carne.

Scăderea concentraţiilor ionilor nitrat şi nitrit şi creşterea concentraţiilor de NDMA şi NDEA dovedesc formarea nitrozaminelor în preparatele din carne pe seama nitritului rezidual, în timpul păstrării acestora.

Determinarea conţinutului în nitrozamine a evidenţiat valori care depăşesc cu mult concentraţia maximă admisă pentru acest tip de produse alimentare.

ISTORIA MEDICINEI

INSTRUMENTS MEDICAUX ROMAINS PROVENUS DE LA PROVINCE MÉSIE INFÉRIEURE

D. Aparaschivei, I. Matei
Académie Roumaine - Filiale Iaşi
L'Institut d'Archéologie Iaşi

ROMAN MEDICAL INSTRUMENTS FROM LOWER MOESIA (Abstract) : To elucidate the evolution of society over time, ancient medicine is a very interesting and important researching field. Archaeological discoveries, such as the objects described by this article, but other ancient sources, also, are able to provide a complex framework of medical practice in Roman times. The geographic area that we have like target in this material is the province of Lower Moesia, which includes the territory between Danube and Black Sea (Romanian Dobrodja) and northern Bulgaria. In the present study we present nine ancient medical instruments, from a private collection : two tweezers, two ear probes, a probe-spatula, a probe-spoon, a spoon for pharmacy and two fragments of some kind of hooks used in surgical operations. Most likely, we have a mixed medical kit with tools used in general medicine, surgery, in preparation of the pharmaceutical treatments, but very possible, also, in cosmetic practices. Publication of these archaeological materials is, in addition to an extra page in the history of ancient medicine, a pretext for stepping up in a research field that, in other regions of the former Roman Empire, it is a great interest for researchers. **Key words** : ANCIENT MEDICINE, MOESIA INFERIOR, MEDICAL INSTRUMENTS

Les civilisations antiques associaient le corps et la raison de l'homme au mythique et à la religion. Les causes des défauts physiques et des maladies étaient cherchées, surtout dans l'Orient antique, au monde divin. Ce sont les Grecs ceux qui ont essayé concilier une vision rationnelle sur les concepts de santé et de maladie avec la foi pour les Dieux (1,2,3,4,5). L'école d'Alexandrie a représenté un moment clé pour l'évolution de la médecine „intuitive" vers la médecine scientifique (6,7). Les pratiques anatomiques et physiologiques sont devenues scientifiques, grâce à la pléiade de médecins y venus de Grèce entière (8).

L'étape suivante pour le cours de la médecine antique, la plus importante, a été le «transplant» des connaissances grecques dans le monde romain (9). Sans cette transposition, la médecine grecque serait restée, probablement, au niveau de celle d'Egypte ou Babylone (10). Dans une première phase, qui correspond à l'époque républicaine, le respect pour des médecins manque. Les esclaves et les affranchis exerçaient ce métier, mais sans bénéficier de la protection de l'Etat (11,12).

César a accordé des droits à ceux qui pratiquaient des professions libérales (11). Suétone en parle : "*Omnes professos et liberalium artium doctores, quo libentius et ipsi urbem incolerent, et coeteri appeterent, civitate donavit"* (13). Ce moment a marqué le véritable essor des médecins et, implicitement, leur intérẹt pour pratique et recherches a grandi (14). Excepté les médecins généralistes, nommés dans des inscriptions *medici clinici*, il y en avait des médecins spécialisés pour chaque partie du corps (14,15,16,17,18,19,20,21). Leurs connaissances deviennent mises en pratiques dans tous les milieux sociaux. Les médecins des

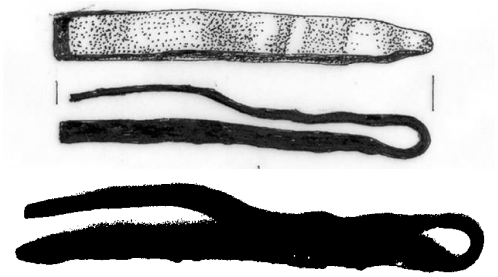

Fig. 1. Pincette

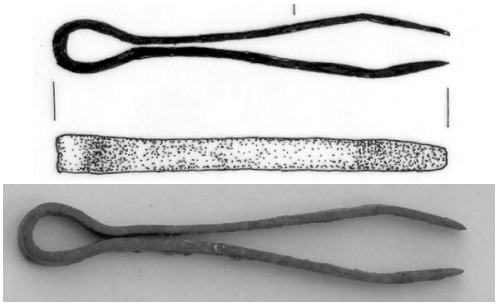

Fig. 2. Pincette

cours impériales sont devenus indispensables (12) ; c'est, aussi, le cas des unités militaires (5,22,23,24,25), des grandes cités, ou des petites communautés. Ils y étaient męme venus d'autres villes (26). Les instruments médicaux utilisés, les diverses branches de la médecine (2) et les spécialisations des médecins (27) ont pris se diversifier. En ce qui concerne les instruments médicaux, ils ont été découverts dans tout le monde romain, surtout dans des sépulcres (28,29). Gallia Belgica, Germania Inferior et Germania Superior sont les provinces le mieux représentées (30).

Quant aux pratiques médicales en Moesia Inferior, l'historiographie s'en est occupée, sans épuiser le sujet (31,32,33,34,35, 36,37,38,39). Assez souvent, les artefacts médicaux sont publiés dans un contexte général, sans une description complexe et en omettant des détails sur leur utilité (40, 41,42,43). Les inscriptions et les instruments médicaux y découverts jusqu'à ce moment prouvent que la médecine était réservée aux spécialistes (26,44,45,46,47).

Cette étude propose une analyse des nouveaux instruments médicaux et de pharmacie (provenus d'une collection privée) découverts en Dobroudja (fig. 10). Il s'agit de neuf pièces en bronze, d'emploi divers, du Nord de cette région.

1. Pincette (gr. λαβιζ, lat. *vulsella, volsella*) (48) à un bras droit et l'autre courbé, confectionnée d'une seule bande de bronze pliée. Dimensions : L= 62 mm ; poids= 9,40 g. (fig. 1) ; Ier –IIe siècle ap. J.- Ch.

2. Pincette à deux bras courbés (gr. λαβιζ, lat. *vulsella*, *volsella*) ; bronze. Dimensions : L= 59 mm ; poids = 5,20 g. (fig. 2) ; Ier –IIe siècle ap. J.- Ch.

Utilisées dans les pratiques chirurgicales, la médecine générale ou la pharmacie, les pincettes, fréquemment découvertes dans des trousses médicales, avaient des formes les plus diverses (22,48). Il y avait aussi des pinces à forme de pincette, mais avec des extrémités prévues des dents pour empoigne et fixation.

3. L'état assez précaire de ce fragment rend son identification difficile. La partie

Fig. 3. Fragment d'instrument utilisé en chirurgie

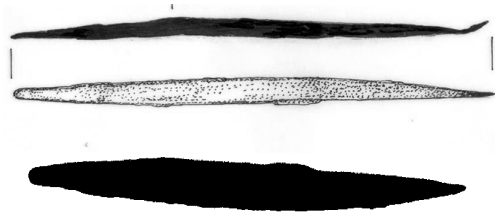

Fig. 4. Fragment d'instrument utilisé en chirurgie (crochet ?)

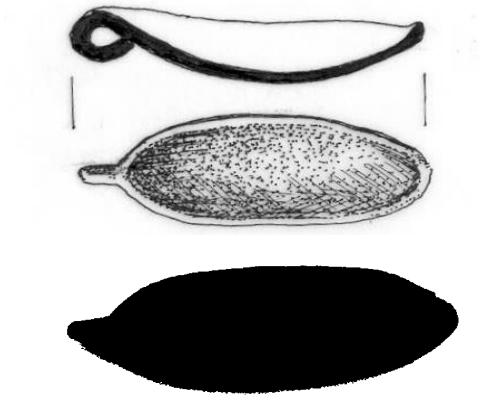

Fig. 5. Cuillère

pointue pouvait aider en stomatologie ou pour les interventions ophtalmologiques ; bronze ; Dimensions : L= 100 mm, poids = 7,50 g. (fig. 3) ; Ier–IIe siècle ap. J.- Ch.

4. Comme le fragment antérieur, l'emploi de cette pièce nous reste assez ambigu (peut ętre un crochet pour des opérations chirurgicales simples) (49) ; bronze ; Dimensions : L = 93 mm, poids = 7,00 g. (fig. 4) ; IIe siècle ap. J.- Ch.

5. Petite cuillère pharmaceutique ovale, prévue d'un crochet dont s'attache la manche ; bronze ; Dimensions : diamètre de la circonférence verticale = 40 mm ; diamètre de la circonférence horizontale = 12 mm ; poids = 3,30 g. (fig. 5) ; IIe siècle ap. J.- Ch.

Ces petites cuillères pharmaceutiques sont de types et dimensions diverses et différents moyens pour la fixation de la manche (48). Cette pièce ne garde pas sa manche, mais le système était classique : ancrée par une tige dans l'oreille de la base (50).

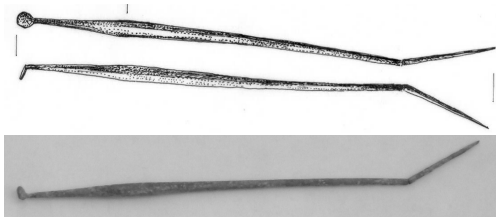

Fig. 7. Sonde auriculaire

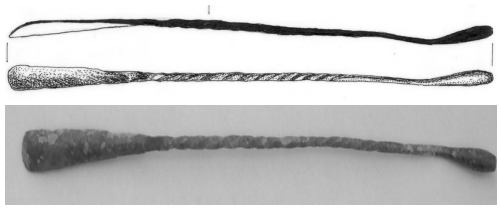

Fig. 6. Sonde-cuillère

6. Cuillère sonde (gr. Κυαθομηλη, lat. *cyathiscomela*) ; bronze ; Dimensions : L= 152 mm ; poids = 4,10 g ; L cuillère = 35 mm (fig. 6) ; IIe siècle ap. J.- Ch.

Nommée en Antiquité μηλη, μηλωτιζ/ μηλωριζ ou *specillum* (51), l'instrument est rond en section, s'amincit à un bout et se prolonge avec une petite cuillère allongée et aplatie à sa pincée. L'autre bout se termine en noyau d'olive (48). La partie à manoeuvrer, notamment le centre de la sonde, est tordu pour une meilleure prise et pour une utilisation rapide et facile.

Utilisée dans les pratiques pharmaceutiques, une extrémité pour combiner les divers ingrédients et l'autre pour peser les quantités de médicaments recommandés, la petite cuillère servait comme curette pour de divers tissus. Un tel instrument, qui se remarque par son ornement, a été découvert à Callatis, dans un tombeau daté à la moitié du IIe siècle ap. J.- Ch. (32,41). On en connaît autres pièces aux environs (43,52).

7. Sonde auriculaire (gr. μηλωτιζ, lat. *specillum oricularium* ; *auriscalpium*) ; bronze ; Dimensions : L= 135 mm ; poids = 4,10 g (fig. 7) ; Ier–IIe siècle ap. J.- Ch.

Sa partie inférieure est bien pointue et polie. La petite cuillère de l'autre coté, *ligula*, est plate et de petites dimensions.

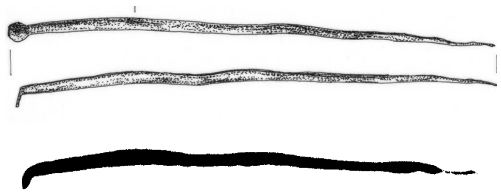

Fig. 8. Sonde auriculaire

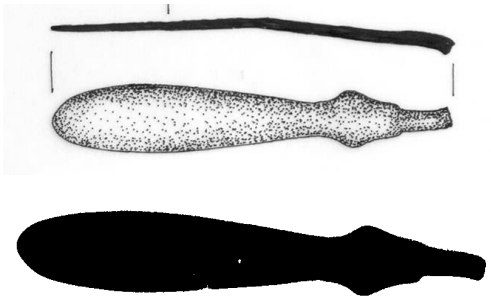

Fig. 9. Fragment de sonde - spatule „poisson"

La courbure de l'extrémité pointue nous frappe, étant, probablement, employée dans autres buts. Dans la région Radomir (province Thrace), bien possible un centre de production pour de petits objets en bronze, ont été découvertes 20 sondes, environ (53).

8. Sonde auriculaire (gr. μηλωτιζ, lat. *specillum oricularium* ; *auriscalpium*) ; bronze ; Dimensions : L=127 mm, poids = 4,40 g (fig. 8) ; Ier –IIe siècle ap. J.- Ch.

Comme la pièce antérieurement présentée, elle a une extrémité bien pointue, mais droite. L'extrémité de l'autre coté se finit par la męme petite cuillère très fine et aplatie (*ligula*) (48).

Les médecins spécialistes, nommés *medici auricularii* (14), s'aidaient des sondes d'oreilles ou auriculaires (*auricullarium specillum)* pour éloigner les intrus et les parasites (54).

En Asie Mineur, ces instruments servaient comme des sondes mais aussi comme des cautères (gr. Καυτηριον, lat. *ferrum candens*) (55). Leur grand nombre prouve qu'ils étaient indispensables dans chaque trousse médicale, grâce aux emplois multiples. Leurs dimensions étaient variables.

9. Fragment de sonde spatule (gr. σπαθομηλη, lat. *spathomela*) de type „poisson" (29,48) ; bronze ; Dimensions : L de la spatule = 69 mm, poids = 6, 30 g (fig. 9). Ier –IIe siècle ap. J.- Ch.

Une large gamme d'instruments chirurgicaux la représente ceux pour exploration, dilatation et inspection des cavités et encore les sondes nommées *specillum*. Ces sondes représentaient des outils pour les pratiques médicales, mais encore pour le ménage (56). Hippocrate les mentionne comme instruments pour soigner les blessures de la tęte. Leur utilité est largement décrite par Celse (54,57) et Galien (58). Certains types de sondes sont en usage męme à nos jours (59).

Cet objet y présent a une manche en forme de trapèze d'où commence la partie à manoeuvrer, en se prolongeant, le plus probable, par un pommeau en forme de noyau d'olive (fig. 10). Elle apparaît souvent dans les trousses d'ophtalmologie (60). D'ailleurs, c'est le type de sonde le plus connu. A l'une de ses extrémités pouvait avoir, au lieu d'une spatule, une palette ou une cuillère. Ces modifications étaient faites pour simplifier la trousse.

Ces sondes servaient en pharmacie et, en męme temps, dans les pratiques de la médecine générale. L'extrémité ronde était employée comme sonde, dirigeant du bistouri (gr. μαχαιρα, σμιλμ, lat. *culter, scalper, scalpellus*), et pour cautériser. L'extrémité spatule servait pour écraser et combiner les poudres, les liquides et les onguents et pour saupoudrer, pour dégoutter les

Fig. 10. Des instruments médicaux en bronze de la province romaine Mésie Inférieure (Ier – IIe siècle ap. J.- Chr.)

lotions dans les yeux. Dans les cuillères, étaient dissoues les diverses poudres (60). Elles étaient utilisées, sans doute, pour la séparation des colorants dans la cosmétique (29,49,56,61). Ces emplois multiples expliquent leur grand nombre (27,49,62).

On ne dispose pas d'informations concernant le cadre archéologique ou autres preuves (objets associés qu'on puisse dater). Pourtant, on sait bien qu'il n'y a pas une évolution importante quant à la forme des ustensiles appartenant aux premiers siècles de l'ère chrétienne. Prenant pour repère des objets similaires de la même région ou de l'Empire, on pourrait placer cette trousse médicale, cosmétique ou toutes les deux, dans les premiers deux siècles ap. J. - Ch.

Ces instruments ont probablement appartenu à un médecin pratiquant de la médecine générale, mais qui possédait des connaissances nécessaires pour de simples interventions chirurgicales. La diversité de leur utilisation nous fait croire qu'il n'était pas un spécialiste et pouvait guérir plusieurs maladies. Cette situation est valable pour le monde romain où on connaît des médecins avec multiples spécialisations (27).

NOUTĂŢI

Cryptochrome - legătura dintre ceasul biologic şi diabetul zaharat

Creşteri ale nivelelor circulante de glucagon şi adrenalină, doi hormoni care activează gluconeogeneza hepatică, declanşează fosforilarea mediată de AMPc a factorului de transcripţie Creb *(cAMP response element–binding protein)* şi defosforilarea co-activatorului 2 al Creb *(Crtc2, Creb-regulated transcription coactivator-2)*. Prin controlul sintezei de AMP ciclic, Cryptochrome reglează activitatea Creb în ficat. În acest fel, sinteza de glucoză în ficat este legată prin intermediul perioadelor interprandiale şi a celor de somn de funcţionarea ceasului biologic. Activitatea Creb în timpul perioadelor interprandiale este modulată de Cry1 şi Cry2, ritmic exprimate de către ficat. Expresia Cry1 creşte în timpul tranziţiei de noapte-zi, atunci când se reduce expresia genelor implicate in gluconeogeneză prin blocarea creşterii mediate de glucagon a concentraţiei AMPc intracelular şi a fosforilarii Creb mediată de Protein kinaza A. În studiile biochimice, s-a constatat că, Cry1 a inhibat acumularea de cAMP ca răspuns la activarea unei proteine G cuplate la receptor, dar nu şi la forskolin, un activator direct al adenilat ciclazei. Proteinele Cry par să moduleze direct activitatea proteinelor G cuplate la receptori prin intermediul subunităţii Gsá. Supraexpresia hepatică a Cry1 a scăzut nivelul glucozei din sânge şi a îmbunătăţit sensibilitatea la insulină la şoarecii insulino-rezistenţi db/db, ceea ce sugerează că acei compusi care amplifică activitatea Cryptocrom pot oferi beneficii terapeutice in DZ de tip 2 (Zhang EE, Liu Y, Dentin R, Cryptochrome mediates circadian regulation of cAMP signaling and hepatic gluconeogenesis. *Nat Med* 2010 ; 16 (10) : 1145-1151).

RESEARCHES REGARDING EXTENDED-SPECTRUM BETA-LACTAMASES PRODUCE BY ENTEROBACTERIA STRAINS (Abstract): **Aim**: To evaluate the susceptibility of extended spectrum beta-lactamase (ESBL) producing organisms among *Escherichia coli* and *Klebsiella pneumoniae*, isolated between January-October 2009 from hospital and community. **Materials and methods**: From 611 enterobacteria strains, for 112 strains (*E. coli*, n=84 and *K. pneumoniae*, n=28), the ESBL phenotypic confirmation was performed with double disk test (DDT) and the replacement disk method. The minimum inhibitory concentrations (MICs) for next antimicrobial agents tested: ceftazidime, cefotaxime, ceftriaxone, cefepime, cefpirome, imipenem, meropenem, ertapenem, moxifloxacin, gatifloxacin, levofloxacin, ofloxacin were performed by agar dilution method. Resistance rates were reported using the *Clinical Laboratory Standard Institute* (CLSI) breakpoints for the fully susceptible category; moderately susceptible isolates were classified as resistant. *K. pneumoniae* ATCC 700603 and *E. coli* ATCC 25922 were used for quality control. **Results**: Resistance rates for ceftazidime, cefotaxime, ceftriaxone and aztreonam among tested strains were very high: 84.5%, 100%, 100% and 96.4% for *E. coli* and 98.8%, 98.8%, 97.6% and 89.2% for *K. pneumoniae*, with the MIC90 values > 256 mg/L for either antimicrobial tested agent. The MICs for fourth generation cephalosporins ranges from 4 mg/L to 512 mg/L. The MICs for tested quinolones were > 2 mg/L for 89.2% strains. Using breakpoint for susceptibility, all isolates were sensitive to ertapenem, imipenem and meropenem. **Conclusions**: We noticed a high resistance rate for ceftazidime, cefotaxime, ceftriaxone and aztreonam. In this study, carbapenems demonstrated the highest degree of activity. **Key words**: EXTENDED SPECTRUM BETA-LACTAMASE, ENTEROBACTERIA, ANTIMICROBIAL RESISTANCE

Tulpinile de *Escherichia coli* şi *Klebsiella pneumoniae* producătoare de beta-lactamaze cu spectru extins (BLSE) constituie cele mai comune bacterii gram-negative cu rezistenţă multiplă la antibiotice (1). Beta-lactamazele cu spectru extins sunt enzime care conferă rezistenţă la cefalosporinele de generaţia a treia (e.g., ceftazidim, cefotaxim şi ceftriaxonă) şi monobactame (e.g., aztreonam), dar care nu afectează cefamicinele şi carbapenemele. Deşi aceste enzime conferă rezistenţa la cefalosporinele cu spectru extins şi la aztreonam, diversitatea BLSE determină profiluri variate de sensibilitate pentru alte beta-lactamine (2). Din acest motiv, este absolut necesar ca laboratoarele clinice să fie capabile să depisteze rezistenţa determinată de BLSE (3).

Scopul studiului a fost de a evalua rezistenţa la agenţi antimicrobieni a unor tulpini de *Escherichia coli* şi *Klebsiella pneumoniae* producătoare de beta-lactamaze cu

spectru extins în vederea descrierii profilului de rezistenţă şi al selectării tulpinilor pentru studii viitoare de biologie moleculară.

MATERIAL ŞI METODE

Tulpini bacteriene

Am testat 112 tulpini de *Enterobacteriaceae* (84 tulpini de *Escherichia coli* şi 28 tulpini de *Klebiella pneumoniae*, selectate dintre 611 enterobacterii pe baza antibiogramelor prin metoda difuzimetrică, ca test *screening* iniţial recomandat de *Clinical Laboratory Standard Institute* (CLSI) (4). Tulpinile testate, identificate prin teste convenţionale şi cu sistemul automat mini-API (bioMerieux), au fost izolate de la pacienţi şi purtători sănătoşi în diverse produse patologice (urină, abcese, materii fecale), în perioada ianuarie-octombrie 2009.

Pentru controlul de calitate am utilizat tulpinile martor pozitiv, respectiv negativ pentru producerea de BLSE: *K. pneumoniae* ATCC 700603 şi *E. coli* ATCC 25922.

Agenţi antimicrobieni

Am determinat concentraţia minimă inhibitorie (CMI) pentru următorii agenţi antimicrobieni: ceftazidim, cefotaxim, ceftriaxonă, cefepim, cefpirom, aztreonam, imipenem, meropenem, ertapenem, moxifloxacin, pefloxacin, levofloxacin şi gatifloxacin, obtinuţi din surse comerciale şi testaţi în 12 concentraţii diferite, cuprinse între 0,06 şi 512 mg/L.

Testarea sensibilităţii

Concentraţiile minime inhibitorii au fost determinate prin metoda diluţiilor în agar Mueller-Hinton, conform recomandărilor CLSI (4). După inocularea cu aproximativ 10^5UFC/spot, plăcile au fost incubate peste noapte la 37^0C. Concentraţia minimă inhibitorie (CMI) a fost considerată ca cea mai mică diluţie de antibiotic fără creştere per spot. Categoriile de sensibilitate le-am stabilit conform punctelor de ruptură (*breakpoints*) recomandate de CLSI (4) pentru categoria total sensibil (izolatele moderat rezistente au fost clasificate în acest studiu, ca fiind rezistente).

Analiza statistică

Analiza statistică am efectuat-o prin stabilirea procentelor tulpinilor inhibate la o anumită valoare a CMI, calcularea valorilor CMI 50 şi CMI 90 şi a ratei de rezistenţă faţă de agenţii testaţi. Valorile CMI 50 şi CMI 90 reprezintă concentraţia minimă inhibitorie care inhibă 50%, respectiv 90% din izolatele investigate.

REZULTATE ŞI DISCUŢII

Tabelele I şi II însumează datele privind sensibilitatea tulpinilor studiate faţă de agenţii antimicrobieni testaţi, prezentate ca valori ale CMI 50, CMI 90, limite ale CMI şi rata rezistenţei.

Rata de rezistenţă a tulpinilor de *E. coli* la cefalosporinele de generaţia a 3-a a fost foarte crescută: 84,5%, pentru ceftazidim şi 100%, pentru cefotaxim şi ceftriaxonă. Pentru tulpinile de *K. pneumoniae*, rata de rezistenţă a fost cuprinsă între 97,6% (la ceftriaxonă) şi 98,8% (la ceftazidim şi cefotaxim). Rezistenţa pentru aztreonam a fost detectată la 96,4% dintre tulpinile de *E. coli* şi 89,2% dintre tulpinile de *K. pneumoniae* testate. În studiul nostru, valorile CMI 90 pentru fiecare cefalosporină de a 3-a generaţie testată au fost >256 mg/L, iar pentru cefalosporinele de generaţia a 4-a, >128 mg/L. Valorile CMI pentru fluoroquinolonele testate au fost >2 mg/L pentru > 89,2% dintre tulpinile de *E. coli* şi >71,43% dintre tulpinile de *K. pneumoniae* investigate. Microorganismele producătoare de BLSE pot fi selectate în urma unor greşeli în terapia cu antibiotice. Beta-lactamazele cu spectru extins apărute pot fi detectate cu dificultate, pentru că ele au niveluri diferite de activitate asupra cefalosporinelor.

Conform standardului CLSI (4), tulpinile care au valori ale CMI pentru cefpodoxim, ceftazidim, aztreonam, cefotaxim sau

TABELUL I

Activitatea *in vitro* a agenţilor antimicrobieni testaţi asupra tulpinilor de *E. coli* (n=84)

Agent antimicrobian	CMI (mg/L)			Procent de rezistenţă
	50%	90%	Limite	
Ceftazidim	64	256	0,25-512	84,52
Cefotaxim	128	512	32-512	100
Ceftriaxonă	256	512	16-512	100
Cefpirom	128	256	64-512	100
Cefepim	64	128	8-256	96,4
Aztreonam	128	256	4-512	96,4
Imipenem	0,06	0,06	0,06-0.5	0
Meropenem	0,06	0,06	0,06-0,06	0
Ciprofloxacin	32	64	0,06-128	90
Moxifloxacin	32	64	0,06-128	89,2
Pefloxacin	32	64	0,25-128	89,2
Levofloxacin	32	64	0,06-128	89,2
Gatifloxacin	16	32	0,125-64	89,2

TABELUL II

Activitatea *in vitro* a agenţilor antimicrobieni testaţi asupra tulpinilor de *Klebsiella* spp. (n=28)

Agent antimicrobian	CMI (mg/L)			Procent de rezistenţă
	50%	90%	Limite	
Ceftazidim	64	256	8-512	98.8
Cefotaxim	128	512	8-512	98,8
Ceftriaxonă	256	512	4-512	97,61
Cefpirom	128	256	64-256	100
Cefepim	32	128	4-256	89,2
Aztreonam	128	512	4-512	89,2
Imipenem	0,06	0.06	0,06-0,5	0
Meropenem	0,06	0,06	0,06-0,06	0
Ciprofloxacin	32	64	0,25-128	72
Moxifloxacin	16	64	0,06-128	71,43
Pefloxacin	32	64	0,25-128	71,43
Levofloxacin	16	32	0,06-128	71,43
Gatifloxacin	16	32	0,25-128	71,43

ceftriaxonă ≥2 mg/L trebuie suspectate ca fiind producătoare de BLSE.

La pătrunderea cefalosporinelor de generaţia a 3-a pe piaţa românească în anii '90, fenomenul de rezistenţă a tulpinilor de *Enterobacteriaceae* era absent. Primele tulpini rezistente la aztreonam au fost semnalate în perioada 1991-1995; procentul acestora crescuse semnificativ de la 0,6% la 13% în anul 2002 (5).

Unul dintre cele mai îngrijorătoare aspecte ale rezistenţei producătorilor de BLSE constă în rata crescută de rezistenţă la antibiotice non beta-lactamice, în special la chinolone, trimetroprim-sulfametoxazol şi aminoglicozide (6).

În studiul nostru, rata de rezistenţă la fluoroquinolone a fost remarcabilă: 89,2% pentru tulpinile de *E. coli* şi 71,43% pentru tulpinile de *K. pneumoniae* testate. Într-un alt studiu, rata de rezistenţă la ciprofloxacin a fost de 84% la tulpinile de *E. coli* BLSE pozitive (6). Hal Jones et al. (7) au înregistrat corezistenţă la levofloxacin de 42%. Diferite ţări europene (Grecia, Italia, Spania, Marea Britanie) au raportat un trend

alarmant al rezistenţei asociate cu alte clase de agenţi antimicrobieni între tulpinile producătoare de BLSE (8,9,10,11). Raportat la valorile *breakpoint* pentru sensibilitate, toate tulpinile testate au fost sensibile la carbapeneme. În literatura recentă, carbapenemele au fost cei mai activi agenţi antimicrobieni asupra enterobacteriilor producătoare de BLSE, astfel încât sunt indicate ca tratament în infecţiile cauzate de tulpini de *E. coli* şi *K. pneumoniae* producătoare de BLSE (1, 6). Fenomenul îngrijorător semnalat impune continuarea studiilor privind sensibilitatea la antibiotice a tulpinilor de *Enterobacteriaceae*, în vederea ajustării schemelor terapeutice şi a realizării ghidurilor de tratament conform rezultatelor testărilor prin metode standardizate.

CONCLUZII

Tulpinile studiate prezintă valori crescute ale CMI50 şi CMI90 pentru cefalosporinele de generaţia a treia şi aztreonam, dar nu sunt afectate de carbapeneme, fapt care confirmă supoziţia de producere a BLSE.

Rezultatele noastre demonstrează necesitatea urmăririi, în condiţii standardizate, a sensibilităţii la antibiotice a tulpinilor de *Enterobacteriaceae*.

NOTA

Acest studiu a fost realizat din fonduri proprii ale U.M.F. "Gr.T. Popa", Iaşi, Contract de cercetare nr. 16843/30.09.2009 şi a fost prezentat ca poster la *XXth Congress of European Society of Infectious Diseass and Clinical Microbiology*, Viena, aprilie 2010.

FORMULATION OF CREAMS WITH BETAMETHASONE DIPROPIONATE: EVALUATION OF CHEMICAL STABILITY (Abstract): The aim of this study was to investigate how the different excipients influenced the chemical stability of betamethasone dipropionate in creams. The chemical stability was evaluated by analyzing betamethasone related substance content. Transcutol is the excipient ensuring maximum stability to betamethasone. Incompatibilities between betamethasone dipropionate and hexylene glycol were observed. The pH values in the weak acid range confer chemical stability to betamethasone. **Key words**: BETAMETHASONE DIPROPIONATE, EXCIPIENTS, STABILITY, PH

LAUDATIO

PROFESSOR ALLA VÂȚĂ, M.D., Ph.D.

A CAREER OF SUCCESS

Prof. Alla Vâță, PhD is one of the most important Romanian specialists in the field of infectious diseases. A genuine and dedicated scholar, she is endowed with a rare intelligence. She has always enjoyed the respect and admiration of the whole medical community. She is admired for her excellent professional training that became obvious whenever she presented her opinions about a diagnosis or whenever she taught her undergraduate and graduate students. Her lectures captivated the audience. She is a modest lady and an exact and patient scientist. Prof. Alla Vâță led with a firm hand the Iasi Infectious Diseases Hospital. She was also a remarkable researcher in her field.

She was born in 1920 in Kishinew, where she completed her secondary studies. In the period 1940-1945 she attended the Iaşi Faculty of Medicine**.** Her professors were among others**:** Al. Țupa, C. C. Dumitriu, I. Enescu, I. Tănăsescu, D. Cornelson, all of them outstanding scientists in their field.

In 1945, after a competition she was accepted in the externship program at the Hospital of Infectious Diseases, led by prof. Maria Franche, PhD, who became Mrs Vâță"s model throughout her life. She started her academic career in 1946 at the same clinic. A brilliant career followed: junior teaching assistant, assistant lecturer, lecturer (1952), associate professor (1961), professor (1970). In 1963 she defended her PhD in medical sciences, complemented in 1972 by the highest Romanian academic degree that was awarded after defending the second doctoral dissertation. Prof. Dr. Alla Vâță has been an honorary Member of the Academy of Medical Sciences since 1996.

In 1981 she became consultant on the staff of the Hospital of Infectious Diseases. During her teaching career she supervised 16 doctoral dissertations at the Iasi ″Gr. T. Popa″ University of Medicine and Pharmacy. During this prodigious career she was driven by the desire for continuous improvement despite the isolation of Romania from the western world.

Prof. Dr. Alla Vâță enjoyed a remarkable teaching career**.** She used to teach the 6th year medical students and postgraduates, being admired and respected by all her students and colleagues.

She taught a course of lectures on infectious diseases. Moreover, she managed to create a school of highly trained specialists in infectious diseases, many of them becoming in their turn professors in this field (St. Dumitriu, E. Brauner, V. Luca), senior consultants (dr. E. Beşleagă, dr.C. Scurtu), and heads of department from of hospitals all over Romania. All of them were able to solve the most difficult problems this specialty was faced with at that time.

She was a remarkable manager, leading

the most crowded hospital in Moldova during a very difficult period. She managed to make useful changes in the hospital: restructured the patient reception area; had an amphitheater built (1964-1965), upgraded with new equipment the radiology unit; the hospital mortuary (1965), had a new building built for laboratories of bacteriology and chemistry laboratories (1969); the follow-up care unit for epidemic hepatitis patients; complete renovation of the first pavilion, the rooms and entry spaces on the ground floor being turned into a library and reading room for students, doctors and hospital staff.

Prof. Vâță always distinguished herself for the quality of her performance, whether it was about lectures, oral presentations, conferences, roundtables, which she always turned into events exceeding the frame of lectio magistralis and becoming examples of sharing medical practice and highly ethical conduct.

An exquisite clinician, Prof Alla Vâță used to amaze those whom she taught or colleagues by the accuracy of clinical reasoning, amount of knowledge and therapeutic strategy. Besides being a wonderful clinician she was the best and most compassionate doctor, who knew how to approach her patients often with poverty-related diseases and to care for them devotedly. When doctors in other areas were faced with a difficult case she was always the one who was asked for an interdisciplinary examination.

Prof. Dr. Alla Vâță has a very rich scientific activity. She published more than 250 scientific papers. Her research was concentrated on infectious diseases, focusing primarily on issues of utmost importance to public health: viral hepatitis**;** ECG changes in some bacterial and viral diseases (exanthematic typhus was a national priority); studies on measles, mumps and typhus**;** zooanthroponoses **(**anthrax, tularemia, Q fever, and leptospirosis); studies on bacterial and viral meningitis; sepsis. She published the first treatise on infectious diseases in 1971, reprinted in 1978, "Infectious Diseases Update", Junimea Publishing House, Iaşi, 1975, and also the chapter "Therapy of infectious diseases" in the Therapeutic Guidelines" (three editions).

She is an active member in the medical life of Romania. She attended numerous national infectious disease congresses, conferences, symposia in Bucharest, Iasi, Constanta, Cluj, Tg. Mures, and in the annual scientific sessions organized by the University of Medicine and Pharmacy and the Society of Physicians and Naturalists from Iasi. Her presentations of the results of her research work have always been well received by other specialists. She also contributed directly to the organization of many scientific events in Moldova. She attended various scientific meeting abroad: The Balkan Medical Week in Istanbul (1968), Belgrade (1970), Athens, etc. She was elected president and vice-president of national congresses on infectious diseases. She presented her papers at the Congresses of the International Society for Infectious Diseases and Parasitology in Vienna (1970), Warsaw (1974), (at this congress she was elected member of the International Society Committee), Varna (1978), Cairo (1985). She also presented papers at the International Congress of Infectious Diseases, held in Jerusalem (1989). Last but not least, the syntheses of her researches at conferences held in Copenhagen and Lund as part of the experience exchange programs (1971).

She is a member of important national and international scientific societies: Presi-

dent of the Romanian Society for Infectious Diseases, Microbiology and Epidemiology (1972-1985), Society of Physicians and Naturalists of Iaşi (secretary1972 – 1974, president 1974- 1979, vice-president 1979-1990, honorary president (1990 to the present), the Balkan Medical Union (secretary of the national committee), member of the Romanian Association of Scientists, Iasi Branch, since 1981, International Society for Infectious Pathology and Parasitology (member since 1972, member of society committee 1976-1982).

Professor Alla Vâță was member of the editorial board of many important medical publications (*Medical Surgical Journal, Bacteriology, Virology, Parasitology, Epidemiology,* and *Journal of Preventive Medicine*).

She served with honor and efficiency various administrative roles at the Gr. T. Popa University of Medicine and Pharmacy and the Ministry of Health. In this respect, it is worth mentioning that in 1972-1973 she was appointed deputy rector.

For the entire activity she was awarded diplomas of honor and excellence: Medal of Labor (1969), Sanitary Merit Medal (1971), Scientific Merit Order Class III (1971), "Gold Diploma" for outstanding achievements in the Red Cross activity (1972), Medal "25 Since the Proclamation of the Republic" (1972), Physician emeritus (1973), Order of Labor class III (1976), Professor emeritus (1980), Member emeritus of the Academy of Medical Sciences (1993), Honorary Member of the Romanian Association of Scientists (1996), Honorary member of the academic staff of the Iasi "Gr. T. Popa" University of Medicine and Pharmacy (1997), Diploma of Excellence of the Iasi College of Physicians (2000), Medical Merit Order in the rank of Commander (2004).

Along with other great personalities of Iasi medicine, Professor Alla Vâță is included in the gallery of the personalities who contributed to the progress and modernization of health care in Romania.

Happy Anniversary our Dear Professor Alla Vâță!

E. Târcoveanu

O POSIBILITATE DE DETECȚIE A POTENȚIALULUI P300 CU AJUTORUL TRANSFORMATEI WAVELET MULTIREZOLUȚIE

Roxana Aldea[1], Anca Mihaela Lazăr[2]

THE POSSIBILITY OF A MULTIRESOLUTION WAVELET APPROACH FOR DETECTING THE P300 EVENT RELATED POTENTIAL (Abstract): The main objective is to highlight the P300 potential on certain electroencephalographic signals. P300 occurs at a relatively well defined time in relation to a stimulus and it represents a signal with a specified band frequency. **Method:** The electroencephalographic (EEG) was recorded with 4 wet electrodes by means of g.MOBIlab+ module, a g.tec acquisition system. The multiresolution wavelet transform was chosen to extract the P300 potential from the EEG signal because it provides information on both time and frequency domains. **Results:** The multiresolution wavelet transform decomposes the signal in sub-bands and it helps to highlight the P300 potential. The spectrum of the P300 potential is around 3Hz. For the multiresolution wavelet decomposition this corresponds to coefficients of approximation of order 4 according to 0 to 60 Hz band of the original EEG signal. The representation of these coefficients emphasizes a better detection of P300 potential then in the original signal. **Conclusion:** It is shown to be a more appropriate method than the direct analysis of the signal because it works with lower dimensional signals. This method of detection of the P300 potential can be used successfully in the implementation of a Brain Computer Interface (BCI). **Key words**: BRAIN COMPUTER INTERFACE, EEG, P300, MULTI-RESOLUTION WAVELET TRANSFORM.

Posibilitatea de a comunica cu alte persoane prin intermediul vorbirii, al gesturilor sau al scrisului reprezintă unul dintre factorii care fac ca fiecare ființă umană să se poată bucura de viață. Persoanele care au anumite afecțiuni motorii (cei ce suferă de aşa-numitul sindrom al imobilizării - „locked-in syndrome") nu au posibilitatea să exprime idei, dorințe sau sentimente. Afecțiunea (de exemplu scleroză amiotrofică laterală, atac cerebral sau polineuropatie severă) se manifestă prin pierderea completă a controlului voluntar asupra muşchilor. Pacienții ce prezintă acest sindrom sunt deplin conştienți de ceea ce se întâmplă în mediul înconjurător şi prezintă o activitate cerebrală normală (electroencefalogramă normală), dar nu sunt capabili să comunice nici măcar nevoile de bază sau să se mişte, cu alte cuvinte sunt prizonieri în propriile corpuri.

O modalitate de a le oferi un anumit grad de autonomie şi posibilități minimale de comunicare o constituie integrarea într-un sistem alternativ pentru comunicare şi control, cunoscut sub denumirea de „Inter-

faţă Creier-Calculator". Ideea de bază a unui sistem BCI este aceea de a măsura activitatea electrică, magnetică sau orice alte manifestări fizice ale activităţii creierului şi de a le transla în comenzi pentru un calculator sau orice alt dispozitiv (scaun cu rotile, neuroproteză). Altfel spus, scopul BCI este acela de a traduce intenţiile umane - convertite în semnale convenabil alese - în semnale de control pentru un dispozitiv de ieşire.

Potenţialele evocate ERP ("Event related potentials") reprezintă segmente EEG generate de creier atunci când o persoană recepţionează un stimul şi răspunde în mod voluntar la acesta. Aceste tipuri de potenţiale sunt utilizate pentru BCI şi pentru detectarea unor boli neurologice.

Unul dintre aceste potenţiale este potenţialul P300, care este o deviaţie pozitivă în EEG-ul uman care apare la aproximativ 300-400ms după prezentarea neaşteptată a unor stimuli relevanţi. Timpul de apariţie a acestei componente poate varia de la 250 ms chiar până la 900 ms cu amplitudini de la minimum 5μV până la limita uzuală de 20μV pentru potenţialele auditive şi cele evocate vizual. Spectrul de frecvenţă al potenţialul P300 este situat la frecvenţe joase, în jur de 3 Hz (1).

Farwell şi Donchin au demonstrat că potenţialul P300 poate fi utilizat pentru citirea cuvintelor atunci când se utilizează aşa numita paradigmă "odd-ball" (2).

Întrucât P300 apare la un moment relativ bine determinat de timp în raport cu un stimul şi de asemenea reprezintă un semnal cu frecvenţa situată într-o bandă foarte îngustă şi de asemenea destul de bine precizată, pentru extragerea acestuia din semnalul EEG s-a optat pentru transformata wavelet, ce oferă informaţii legate atât de timp, cât şi de frecvenţă.

MATERIALE ŞI METODĂ

Analiza wavelet multirezoluţie

Transformata wavelet multirezoluţie oferă posibilitatea analizei semnalelor nestaţionare. Transformata wavelet poate analiza aceste semnale la diferite rezoluţii prin descompunerea acestora în benzi de frecvenţă. Această metodă a fost dezvoltată pentru a rezolva deficienţele transformatei Fourier scurte (STFT Short time Fourier Tranfform).

În cazul transformatei wavelet continue, semnalele sunt analizate prin scalarea si translarea unei funcţii wavelet mamă (3). Tranformata wavelet discretă (DWT) este reprezentarea timp-scală bazată pe metode digitale de filtrare. Transformata wavelet discretă analizează semnalele la diferite rezoluţii (analiză wavelet multirezoluţie), prin descompunerea semnalului în benzi diferite de frecvenţă. În analiza wavelet, se vorbeşte despre aproximări şi detalii. Aproximările sunt componentele la scale ridicate şi frecvenţe joase. Detaliile sunt componentele la scale joase şi frecvenţe ridicate.

DWT se calculează prin filtrări complementare trece-jos şi filtrări trece-sus succesive şi subeşantionări, metodă cunoscută sub denumirea de algoritmul Mallat (4).

Răspunsul la impuls al filtrului trece-sus (FTS) este notat cu h(n), iar al filtrului trece-jos (FTJ) cu g(n). La fiecare nivel, FTS produce un semnal d(n) al detaliului, în timp ce FTJ asociat cu funcţia de scalare produce un semnal a(n) ce reprezintă o aproximare grosieră. După filtrare FTJ şi FTS şi subeşantionare cu 2 se obţin următoarele semnale:

$$y_J(n) = x(n) * g(n) = \sum_{k=-\infty}^{\infty} x(k) g(2n-k)$$

$$y_S(n) = x(n) * h(n) = \sum_{k=-\infty}^{\infty} x(k) h(2n-k)$$

REZULTATE

Datele au fost înregistrate personal, în laboratorul de Procesare de biosemnale din cadrul Facultății de Bioinginerie Medicală Iași, cu ajutorul sistemului de achiziție de semnale EEG de la firma g.tec din Austria și a platformei BCI2000 (5). Sistemul este format din amplificatorul g.GAMMAbox, g.GAMMAcap cu electrozii și din sistemul de achitiție g.MOBIlab (6). Produsul folosit oferă un sistem de cercetare/dezvoltare complet, sub mediul de programare MATLAB. BCI2000 este o platformă de uz general pentru cercetare și dezvoltare ce dă posibilitatea să se implementeze, evalueze și compare diferite sisteme. S-au făcut înregistrări de la mai mulți subiecți, dar rezultatele prezentate sunt numai de la un singur subiect.

Pacientului -R.A, 25 ani, sănătos- îi este măsurată distanța între inion și nasion și i se așează cap-ul cu electrodul de masă (plasat pe Fpz) la 10% din distanță măsurată, în cazul nostru la 3,9 cm de nasion (conform standardului internațional 10-20).

S-au ales canalele Fz, Cz, Pz și Oz pentru plasarea electrozilor activi, iar electrodul de referință a fost plasat pe urechea dreaptă.

În timpul calibrării, subiectul trebuie să-și fixeze atenția asupra literelor unor cuvinte dintr-o matrice, conform paradigmei propusă de Farwell și Donchin. În varianta actuală a paradigmei, subiectului uman îi este prezentată o matrice cu dimensiunea 6x6 având diverse caractere, evidențiate succesiv, prin modificarea culorii (sau a luminozității) unei linii și/sau coloane. Ori de cate ori o litera, pe care subiectul o cunoaște în prealabil, se află în linia (coloana) evidențiată, în semnalul EEG se generează un potențial P300. Printr-o astfel de corespondență este posibilă comunicarea creier - calculator.

Cu ajutorul sistemului BCI2000, s-a realizat analiza offline a acestor date achiziționate. Analiza offline oferă două rezultate: reprezentarea coeficientului de determinare, r^2, în funcție de timp și canale (7) și afișarea formelor de undă utile pentru investigarea canalelor specifice.

Este reprezentat coeficientul de determinare (fig. 1), unde se poate observa că valorile cele mai ridicate sunt la aproximativ 400 ms față de aplicarea stimulului. Cea mai ridicată valoare corespunde electrodului 3, adică Pz.

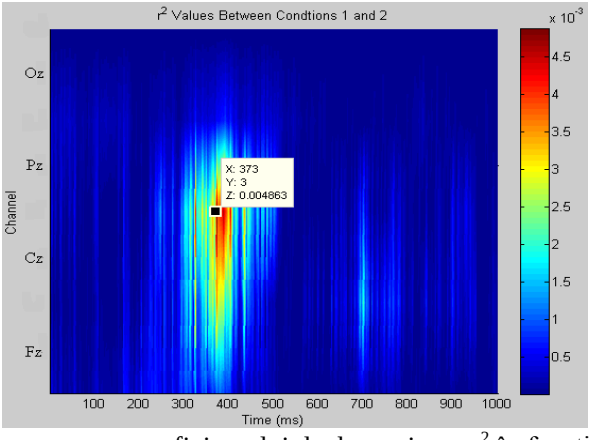

Fig. 1. Reprezentarea coeficientului de determinare r^2 în funcție de timp, pentru canalele Fz, Cz, Pz și Oz

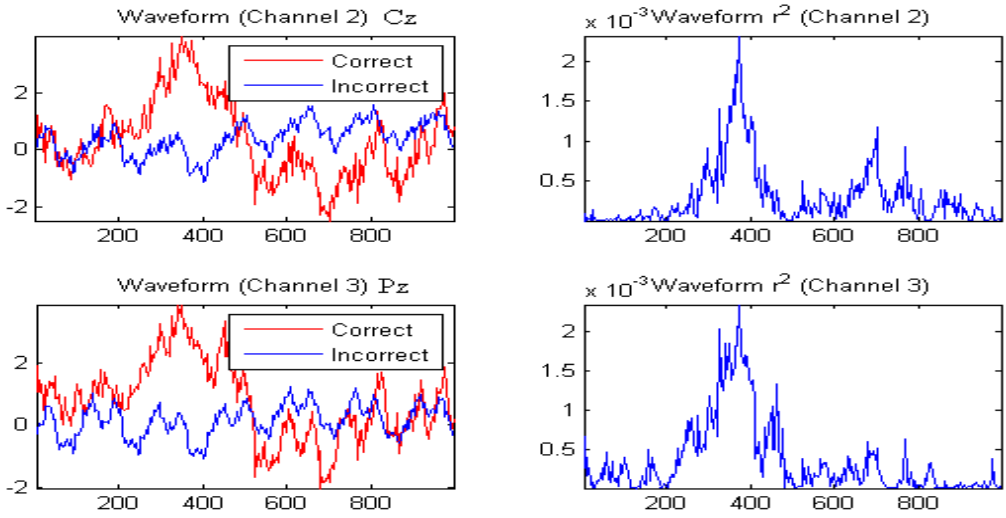

Fig. 2. Reprezentarea EEG pe canalele Cz şi Pz pentru cazul în care se iluminează (corect) şi în care nu se iluminează caracterul dorit (incorect) (partea stângă) şi coeficientul de determinare r^2 (partea dreaptă)

Se observă că potențialul P300 apare la aproximativ 400 ms (fig. 2), ceea ce este în concordanță cu morfologia acestuia. Semnalul notat "Corect" reprezintă semnalul rezultat atunci când litera luminată corespunde cu cea asupra căreia se concentrează subiectul, iar semnalul notat cu "Incorect" semnalul când litera de interes nu este şi cea luminată. În graficul lui r^2 se observă că valorile sale determină un vârf de asemenea la aproximativ 400 ms. Ca formă de undă pentru potențialul P300 s-ar părea că cele mai apropiate rezultate față de cele din literatură s-au obținut pe electrodul Cz. Cele mai relevante valori pentru coeficientul r^2 s-au obținut pentru canalele Cz şi Pz.

Pentru a pune mai bine în evidență potențialul P300 s-a utilizat transfomata wavelet şi descompunerea multirezoluție aplicate pe semnale obținute prin medierea pe linie şi coloană pentru fiecare literă a cuvintelor ce au fost afişate şi urmărite. S-a reprezentat coeficientul de aproximare de ordin 4 (corespunzător benzii 0-4 Hz) pentru literele cuvântului QUICK pe canalele 2 şi 3, respectiv Cz şi Pz. Am reprezentat descompunerea multirezoluție cu waveletul db2 pe 4 nivele pentru media pe linie şi coloană a literei Q pe canalul 3 (Pz) (fig. 3). Mediul de programare folosit a fost MATLAB.

În al doilea grafic (fig. 3), corespunzător coeficientului de aproximare a4 (0-4Hz), pe canalul Pz, se observă o formă asemănatoare unui P300 la aproximativ 450 ms, ceea ce este considerat a fi corect. Pentru observarea potențialului P300 am extras doar coeficientul de aproximare de ordin 4 (fig. 4).

De menționat este faptul că sistemul de achiziție amplifică înregistrările cu 100.

Rezultatele obținute pentru coeficientul r^2 (fig. 2) arată că avem rezultate destul de bune şi pe canalul Cz. Pe acest canal cele mai bune rezultate sunt pentru medierile pe linii şi coloane a literelor U şi I (fig. 5, 6).

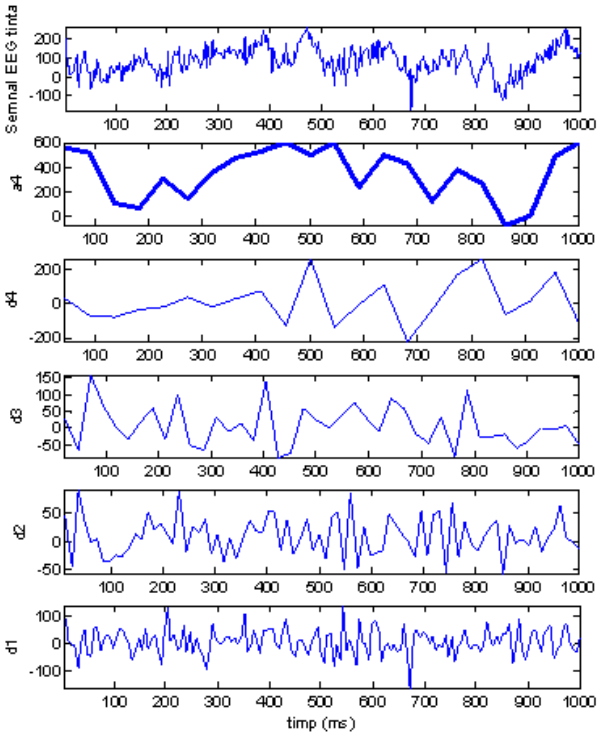

Fig. 3. Reprezentarea descompunerii wavelet (db2) multirezoluție pe 4 niveluri pentru litera Q pe canalul Pz

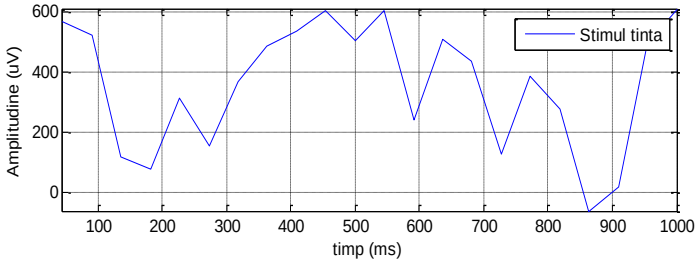

Fig. 4. Coeficienții de aproximare de ordin 4 pentru semnalul țintă (Litera Q, Canal Pz)

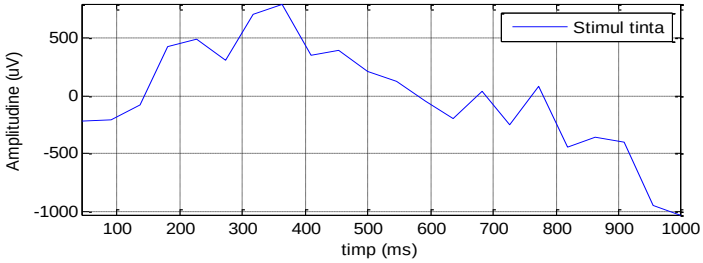

Fig. 5. Coeficienții de aproximare pentru semnalul țintă (Litera U, Canal Cz)

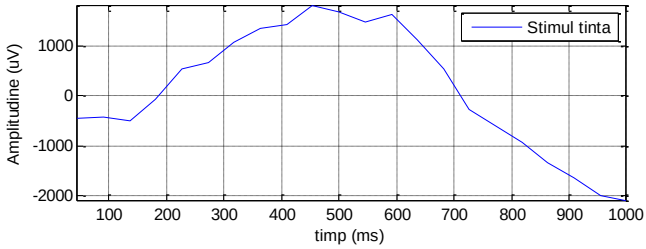

Fig. 6. Coeficienții de aproximare pentru semnalul țintă (Litera I, Canal Cz)

CONCLUZII

În concluzie, analiza wavelet multi-rezoluție, cu wavelet db2, este o metodă de luat în considerare pentru detecția potențialului P300, fiind în avantaj față de metoda directă de analiză a semnalului EEG, când semnalul nu este descompus pe sub-benzi. Metoda permite reducerea dimensiunii datelor, iar acest lucru constituie un câştig important.

S-au prezentat rezultate pentru date achiziționate cu sistemul furnizat de firma austriacă *g.tec* care foloseşte platforma open-souce, BCI2000, cea mai utilizată platformă de către laboratoarele de cercetare din comunitatea BCI. Cu ajutorul analizei offline permisă de această platformă s-a pus în evidență faptul că electrozii Pz şi Cz sunt cei mai potriviți a fi folosiți la detectarea potențialului P300. În majoritatea cazurilor, momentul de apariție este situat în jurul valorii de 400 ms. Rezultatele sunt în concordanță cu unele raportate în literatura de specialitate (8).

MULȚUMIRI

Lucrarea a fost realizată în cadrul proiectului nr. 12115/2008, cu titlul ”*Sistem de investigație, asistare şi control al afecțiunilor neurologice bazat pe interfața creier calculator – BCISIS*”, PNII UEFISCDI din România.

2. Disciplina de Microbiologie

3. Disciplina de Farmacognozie

ANTIMICROBIAL ACTIVITY OF SOME CINNAMIC ACID DERIVATIVES (Abstract): Due to drug-resistance phenomenon, there is a constant need for discovering new antiinfectious agents. A series of cinnamic acid derivatives was synthesized and then brominated with bromine in the presence of chloroform or acetic acid. The structure of the new compounds was confirmed by elemental and spectral data. Their antimicrobial activity was tested by disc-diffusion method. The tested compounds had mainly antifungal activity and were moderately active against Gram-positive bacteria. Bromination of the double bond determined the enhancement of the antimicrobial activity for all the tested compounds. **Key words**: CINNAMIC ACID DERIVATIVES, ANTIMICROBIAL ACTIVITY.

Terapia antimicrobiană reprezintă domeniul ştiinţific care a cunoscut cea mai amplă dezvoltare în secolul al XX-lea, dar cu toate acestea, afecţiunile infecţioase continuă să aibă o incidenţă ridicată în rândul populaţiei. Microorganismele patogene se adaptează la acţiunea antibioticelor şi chimioterapicelor existente, dezvoltând în timp rezistenţă, fenomen care face ca perspectivele de viitor să nu fie foarte promiţătoare. Din acest motiv, sinteza unor noi substanţe cu potenţial antimicrobian prezintă un mare interes.

Studiile efectuate pe derivaţii de acid cinamic au evidenţiat faptul că atât acidul în sine, cât şi derivaţii săi prezintă o activitate antimicrobiană (antibacteriană şi antifungică) importantă (1, 2, 3, 4). Având în vedere faptul că derivatul dibromurat la nivelul dublei legături al acidului cinamic prezintă proprietăţi antibacteriene şi antifungice superioare compusului nebromurat, ne-am propus să sintetizăm o serie de noi derivaţi dibromuraţi de acid cinamic şi să stabilim spectrul acţiunii antibacteriene şi antifungice pentru aceştia, urmărind şi eventuala corelaţie între acţiunea antimicrobiană şi natura chimică a grupărilor grefate pe nucleul aromatic.

MATERIAL ŞI METODĂ

Pentru obţinerea derivaţilor de acid cinamic notaţi I_1-I_9 am folosit reacţia de condensare dintre acidul malonic şi diferite aldehide aromatice (fig. 1) (1, 3).

Derivaţii acidului cinamic obţinuţi (I_1-I_9)

prezintă o legătură olefinică în catena laterală, fapt care permite bromurarea directă, cu obţinerea derivaţilor dibromuraţi vicinali corespunzători, notaţi II_1-II_9 (fig. 2) (5).

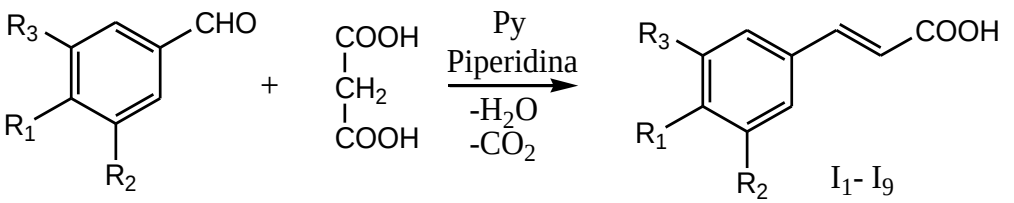

Fig.1. Schema de obţinere a compuşilor de tip I

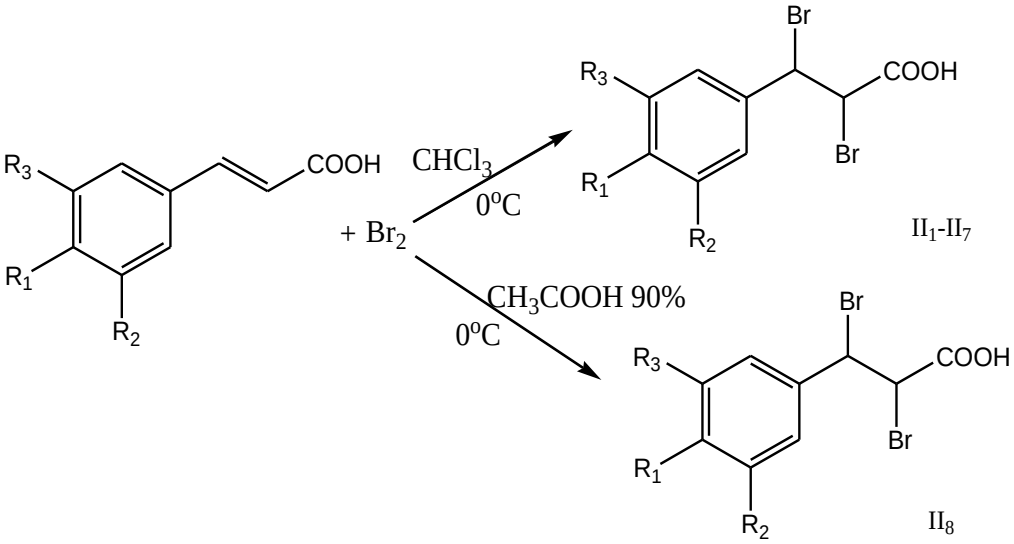

Fig. 2. Schema de obţinere a compuşilor de tip II

Derivaţii dibromuraţi ai acizilor cafeic şi p-hidroxi-cinamic nu au putut fi obţinuţi prin această metodă, produşii de reacţie având o stabilitatea foarte redusă, suferind probabil reacţii de oxidare.

Confirmarea structurii chimice a compuşilor sintetizaţi a fost realizată prin analiză elementală (Elemental Exeter Analytical CE 440 Analyzer) şi analiza spectrelor de vibraţie moleculară în IR (FT-IR Shimadzu Prestige 8400s).

Testarea activităţii antimicrobiene s-a realizat din punct de vedere calitativ prin metoda difuzimetrică folosind bacterii Gram pozitive, Gram negative şi 3 specii de *Candida*.

REZULTATE ŞI DISCUŢII

Compuşii obţinuţi sunt substanţe solide, colorate în alb, alb-gălbui, slab roz sau verde, solubile în alcool, acetonă sau DMSO.

Structura compuşilor de tip I şi II şi unele proprietăţi fizice (greutate moleculară, punct de topire) sunt indicate în tabelul I.

TABELUL I

Caracteristici fizice pentru compuşii de tip I şi II

Compus	R_1	R_2	R_3	Denumirea compusului	Masă moleculară (g/mol)	Punct de topire (ºC)
I_1	-H	-H	-H	acid cinamic	148	134
I_2	$-OCH_3$	-H	-H	acid p-metoxi-cinamic	178	167-8

În continuarea cercetărilor noastre, compuşii sintetizaţi şi acidul cafeic (Fluka) – codificat I_{10} - au fost supuşi testării în vederea determinării din punct de vedere calitativ a activităţii antimicrobiene, prin metoda difuzimetrică folosind următoarele

microorganisme test: *Staphylococcus aureus, Sarcina lutea, Bacillus cereus, Bacillus subtilis, Escherichia coli, Candida albicans, Candida sake* şi *Candida glabrata* (6).

În tabelul III sunt prezentate microorganismele test folosite şi diametrele zonelor de inhibiţie a dezvoltării microorganismelor test, exprimate în mm.

Ampicilina 25 µg	39	35	16	30	16			
Cloramfenicol 30 µg	35	35	26	35	26			
Nistatin 100 µg						26	30	35

Compuşii sintetizaţi au prezentat o activitate antibacteriană moderată, în special asupra bacteriilor Gram pozitive (*Staphylococcus aureus, Sarcina lutea*) şi a bacililor sporulaţi (*Bacillus cereus* şi *Bacillus subtilis*). Niciunul dintre compuşii seriei I nu a prezintat activitate faţă de *Escherichia coli.*

Comparativ cu prima serie de derivaţi,

compuşii grupei II s-au dovedit mai activi. Derivaţii II_6 şi II_8 sunt foarte activi faţă de *Staphylococcus aureus* şi *Sarcina lutea,* având un diametru al zonei de inhibiţie de peste 25 mm în timp ce II_7 este activ faţă de aceleaşi microorganisme. Derivaţii II_7 şi II_8 sunt totodată activi şi faţă de *Bacillus cereus.* În plus, se observă că spectrul de acţiune este extins şi asupra *Escherichia coli*, în cazul compusului II_8.

Încercând să stabilim o interrelaţie structură-activitate antimicrobiană, putem observa că în cazul derivaţilor de acid cinamic, introducerea pe nucleul aromatic a unor grupe cu efect electromer respingător de electroni (de tipul $–OCH_3$, -OH, -Cl, -Br) influenţează în sens negativ activitatea antibacteriană asupra stafilococilor, dar reducerea potenţialului antistafilococic în comparaţie cu acidul cinamic nu este foarte semnificativă. Prezenţa halogenilor pe nucleu (-Cl, -Br), în special a bromului, determină o creştere a activităţii antibacteriene faţă de bacilii Gram pozitivi (*Bacillus cereus* şi *Bacillus subtilis*).

Compuşii sintetizaţi prezintă activitate antifungică remarcabilă, 9 derivaţi dintre cei sintetizaţi (I_1, I_2, I_3, I_6 şi respectiv II_1, II_2, II_6, II_7, II_8) şi acidul cafeic (I_{10}) sunt mai activi decât martorul nistatină, faţă de *Candida albicans*. În cazul tuturor substanţelor investigate, bromurarea dublei legături conduce la o creştere considerabilă a activităţii antifungice, determinând în acelaşi timp şi lărgirea spectrului de acţiune şi asupra speciei *Candida glabrata*, derivaţii de acid cinamic nebromuraţi fiind în general inactivi asupra acestei specii.

CONCLUZII

În cadrul studiilor efectuate s-au realizat următoarele:

- s-au sintetizat 9 compuşi de tip derivaţi de acid cinamic şi 8 compuşi dibromuraţi, derivaţi dibromuraţi ai primei serii;
- structura compuşilor a fost confirmată de rezultatele analizei elementale şi spectrale;
- s-a evaluat acţiunea antimicrobiană a compuşilor sintetizaţi, stabilind că în seria I cinci substanţe (I_1, I_2, I_4, I_5 şi I_7) prezintă activitate faţă de *Sarcina lutea* şi faţă de *Staphylococcus aureus*;
- 9 compuşi (4 de tip I şi 5 de tip II) sunt mai activi decât nistatina, martorul folosit pentru evaluarea acţiunii faţă de *Candida albicans*;

în cazul derivaţilor dibromuraţi la nivelul dublei legături, se remarcă o accentuare semnificativă a potenţialului antibacterian şi antifungic, tendinţă care s-a manifestat la toţi compuşii analizaţi.

NOUTĂȚI

NIVELUL LIPOPROTEINELOR SERICE ÎN CARDIOMIOPATIA TAKOTSUBO VS INFARCTUL MIOCARDIC

Atitudinea recomandată de ghidurile curente la pacienţii cu infarct miocardic sau sindrom coronarian acut include terapia hipolipemiantă agresivă cu statine, indiferent de nivelul de bază al lipoproteinelor serice. Pacienţii cu cardiomiopatie Takotsubo prezintă o simptomatologie similară celei din infarct, beneficiind de aceeaşi atitudine terapeutică în decursul spitalizării. Cu toate acestea, fiziopatologia acestei boli nu include boala aterosclerotică coronariană, putându-se presupune că profilul lipidic este mai puţin modificat pentru aceste cazuri în comparaţie cu cel din infarctul miocardic. Un studiu retrospectiv american a evaluat nivelul seric al lipoproteinelor a jeun la zece pacienţi diagnosticaţi cu cardiomiopatie Takotsubo şi l-a comparat cu profilul lipidic de la 40 de pacienţi (similari din punct de vedere al vârstei şi sexului) cu infarct miocardic. Rezultatele nu au relevat nici o diferenţă între cele două grupuri în ceea ce priveşte valorile colesterolului total (174.5 mg/dL vs. 197.6 mg/dL, $p = 0.12$). Cu toate acestea, în grupul pacienţilor cu cardiomiopatie Takotsubo, valoarea medie a HDL-colesterolului a fost semnificativ mai mare (66.87 mg/dL vs. 36.5 mg/dL, $p = 0.008$) în timp ce valoarea LDL-colesterolului a fost semnificativ mai mică (89.7 mg/dL vs. 128.9 mg/dL, $p = 0.000$), la fel ca şi nivelul trigliceridelor (65.2 mg/dL vs. 166.8 mg/dL, $p < 0.0001$). Aceste rezultate sunt în acord cu mecanismele nonobstructive, non-aterosclerotice ale cardiomiopatiei Takotsubo, fiind recomandată o evaluare individualizată a profilului lipidic înaintea iniţierii terapiei hipolipemiante pe termen lung. PROTECTIVE EFFECTS OF SELENIUM ON ACRYLAMIDE TOXICITY IN THE LIVER OF THE RAT. EFFECTS ON THE OXIDATIVE STRESS (Abstract): Acrylamide (AA), obtained for the first time by Moureu in Germany in 1893, is presently used as polyacrylamide in water treatment and wastewater treatment, paper and pulp processing, mineral processing, crude-oil production processes. Acrylamide is a chemical product formed when frying, roasting, grilling or baking carbohydrate-rich foods at temperatures above 120°C. Acrylamide is thus found in a number of foods, such as bread, crisps, French fries and coffee. Tobacco smoking also generates substantial amounts of acrylamide. Acrylamide administration is associated with significant increase of oxidative stress parameters; acrylamide caused disturbances in the oxidative status and enzyme activities and the effect was pronounced with the high doses. **Material and methods**: This study investigates the effect of selenium (as sodium selenite and as a selenium dietary supplements – Celnium) on the oxidative stress in Wistar rats which received high doses of acrylamide. **Results**: The administration of sodium selenite and selenium dietary supplements (Celnium) significantly increased GSH and GPx levels and decreased MDA compared to group which received only acrylamide. **Conclusions**: Our results show that sodium selenite and selenium dietary supplements (Celnium) can partially prevent the biochemical changes in the liver of the rats which received high doses of acrylamide. **Key words**: ACRYLAMIDE, OXIDATIVE STRESS, SODIUM SELENITE, DIETARY SUPPLEMENTS

Acrylamide is more commonly known as an industrial chemical used to prepare the polymeric material known as polyacrylamide, which is used as a flocculent for treating industrial wastewater and, to a lesser extent, drinking water, as well as having other industrial uses (1).

In April 2002, the Swedish National Food Administration announced their findings that the chemical, acrylamide, could be found in starch-containing foods cooked at high temperatures, such as fried or roasted

potato products and bread. The underlying mechanism of acrylamide formation is not yet known in detail (2). However, researches on food model systems concluded that the Maillard reaction is the main pathway of formation from amino acids (e.g.asparagine) and reducing sugars (e.g. glucose).

The biological consequences of acrylamide exposure have chiefly centered on neurotoxicity ever since this effect was observed in humans occupationally exposed to this compound (3).

Acrylamide is known to cause toxicity to the nervous system in animals and humans at very high levels of exposure, but the threshold for this effect is at a level of exposure that is far greater than the expected exposure from food. Consumption of food where acrylamide has been detected should not result in nerve damage (4-6).

The other health concern regarding acrylamide is its potential to cause genetic damage that may lead to cancer. Experimental exposure of rodents to acrylamide has also revealed a carcinogenic mode of action for this chemical (7).

Glycidamide, a metabolite of acrylamide, binds to DNA and can cause genetic damage. Prolonged exposure has induced tumours in rats, but cancer in man has not been convincingly shown. The International Agency for Research on Cancer (IARC) has classified acrylamide as "probably carcinogenic to humans" (8). Acrylamide is oxidized to glycidamide, a reactive epoxide, and undergoes conjugation with glutathione. DNA adducts from glycidamide have been reported following administration of acrylamide (9).

Kirman et al. (10) reported that the rate of acrylamide conversion to its epoxide metabolite glycidamide is higher during subchronic dosing conditions. Acrylamide caused disturbances in the oxidative status and enzyme activities, and the effect was pronounced with the high doses. The enhancement of lipid peroxidation is a consequence of depletion of glutathione to certain critical levels.

LoPachin et al. (11) suggested that acrylamide induced synaptic dysfunction which involved the adduction of presynaptic protein thiol groups and subsequent reduction in neurotransmitter release. The same author (11) reported that the neurological defects associated with acrylamide intoxication are mediated by impaired neurotransmission at central and peripheral synapses.

Free radicals are continuously produced *in vivo* and there are number of protective antioxidant enzymes (superoxide dismutase, catalase, glutathione S transferase, glutathione peroxidase) and antioxidant glutathione for dealing with these toxic substances (12 -14).

In animals, chronic acrylamide exposure causes neurotoxicity, morphological and biochemical damage in hepatic, renal, nervous and testicular tissues. Nowadays, there is an increased interest in dietary supplements with antioxidant properties that can reduce the effects of deleterious food constituents. Selenium plays an important biological role in living organisms, mainly through its presence in selenoproteins (such as glutathione peroxidases, thioredoxin reductases, iodothyronine deiodinases) (15).

Different toxic effects of acrylamide might be also caused by an increase in lipid peroxidation in case of disfunctions of endogenous antioxidant defence system. Components of this system such as enzymes (glutathione peroxidase, thioredoxin reductase) and reduced glutathione are known to protect biological systems against oxidative stress (16-18).

Selenium is an important biological antioxidant, action in which it is involved as a

part of gluthation-SH-peroxidase, the seleno-enzyme that catalyses reduction of lipid peroxides and of hydrogen peroxide and thus prevents the nocive effects of lipid peroxidation with a high content of unsaturated fatty acids and protects erythrocytes from haemolysis. Selenium protects cells and cell membranes from oxidative processes, facilitating reaction between oxygen and hydrogen and ions transfer at membrane level.

Selenium can have a double action: selenium compounds, sodium selenite among them, have direct pro-oxidant activity leading to acute toxicity but also antioxidant activity, through the process of embodying seleno-proteins and participating in controlling different biological processes within the body (19, 20). As a part of gluthation peroxidase (GSH/Px), selenium is a part of the first and the second level of cell's antioxidant protection.

Increased doses of sodium selenite may reduce inflammation through direct pro-oxidative effect and can increase cell's antioxidant capacity through selenium incorporation in seleno-enzymes (19).

This paper presents preliminary results regarding the protective potential of Selenium (as sodium selenite) and some selenium dietary supplements (Celnium) in the liver of the Wistar rats in experimental oral intoxication with increased dose of acrylamide.

MATERIAL AND METHODS

Chemicals

Acrylamide (C3H5NO, >99% purity) was used in the present study. Acrylamide and all other chemicals were purchased from Sigma Chemical Company.

Animal treatments

Adult Wistar male rats (Laboratory Animal Center of Cantacuzino Institute of Research, Bucharest, Romania), weighing 180-220 g, were housed in groups of five in plexiglas cages with the floor covered with sawdust. Animals were maintained in a controlled environment (12 hours light/dark cycle with lights on at 07.00, temperature of 20±1ºC) before and throughout the experimental period. The rats had free access to food (standard lab rat chow), except 18 hours before the experiment but tap water ad libitum. All experiments involving animals were approved by the University's Committee for Bioethics and animal experimentation according to international rules of conduct.

Studies were carried out using 5 groups of 10 Wistar male rats each which received as follows: group 1 (control) – saline = control group; group 2 – acrylamide (50 mg/kg/day), orally, 10 days = AA group; group 3 – acrylamide (50 mg/kg/day), orally and sodium selenite 1 mg/kg/day orally, 10 days = AA + Se 1 group; group 4 – acrylamide (50 mg/kg/day), orally and sodium selenite 0,2 mg/kg/day orally, 10 days = AA + Se 0,2 group; group 5 - acrylamide (50 mg/kg/day) and Celnium® (dietary supplement containing selenium from Saccharomyces cerevisiae) 0.50mg Se/kg/day orally, 10 days = AA + Ce group.

The previous studies also included groups of rats which received only sodium selenite or selenium from Celnium® (in above mentioned doses) but there were no significant differences compared to the control group.

At the end of treatment, rats were fasted for 12 h before being anesthetized and sacrificed by cervical dislocation. Liver tissues were isolated, washed with saline solution, and stored at -35°C for the biochemical studies. We determined MDA (malondialdehyde), GSH (reduced glutathione), GPx (glutathione peroxidase) as well as TAS (total antioxidant status).

Biochemical study

Liver homogenates analysis

Half-gram sample of liver tissues were homogenized in 4.5 ml KCl 1.5%; the homogenates were used in determination of the hepatic lipid peroxidation end product malondialdehyde (21). MDA level is expressed as µmol/g tissue.

One gram samples of liver tissues were homogenized in 5ml trichloroacetic acid (5%) containing 0.003M EDTA. The homogenates were centrifuged at 2500×g for 15 min. Reduced glutathione was measured in the clear supernatant by spectrophotometric method (22). GSH level is expressed as mmol/g tissue.

In order to investigate the response of the antioxidant systems against high levels of acrilamyde, the activities of glutathione peroxidase (GPx) in whole blood and total antioxidant status (TAS) in plasma were measured using the Randox kit for manual use.

The GPx activityis expressed as U/L. Total antioxidant status is expressed as mmol/L of all antioxidant circulating species in plasma. The statistical analysis was performed using analysis of variance (ANOVA) one way. Tukey test was used for multiple comparisons (software Stats Direct version 2.6). Results are presented as means of three determinations.

RESULTS

The data obtained from the experiments are presented in charts (fig 1-4), representing the level of the determined parameter for each study group.

DISCUSSION

In our study the acrylamide administration (AA group) was associated with statistically significant increase of MDA levels in liver homogenate compared to control group. Furthermore, compared to control group, acrylamide (AA group) caused decrease of glutation in liver homogenate, glutation peroxidase, and total antioxidant status (TAS) in whole blood respectively in plasma. The co-administration of sodium selenite and Celnium with acrylamide was associated with significant increased level of the oxidative stress parameters in the liver omogenate, compared to AA group. The level of MDA in liver homogenate slightly increased in the group receiving acrylamide simultaneously with sodium selenite and Celnium respectively, as hepatoprotective agents.

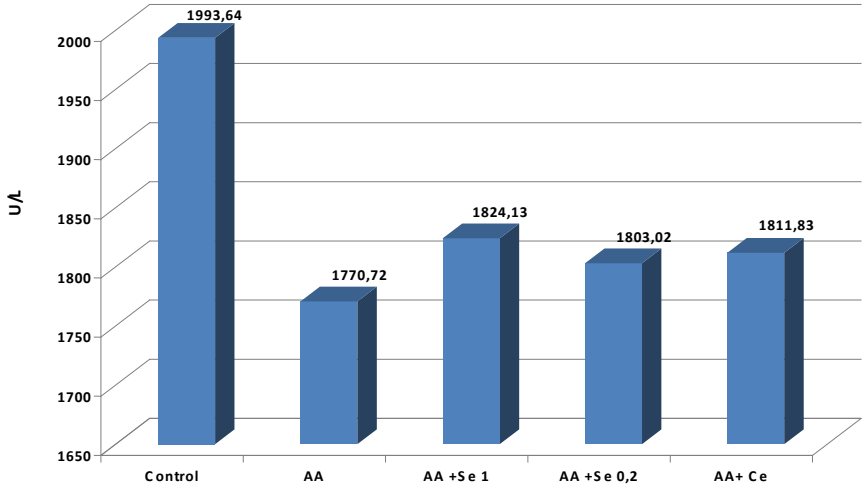

Fig.1. The values of GPx in whole blood

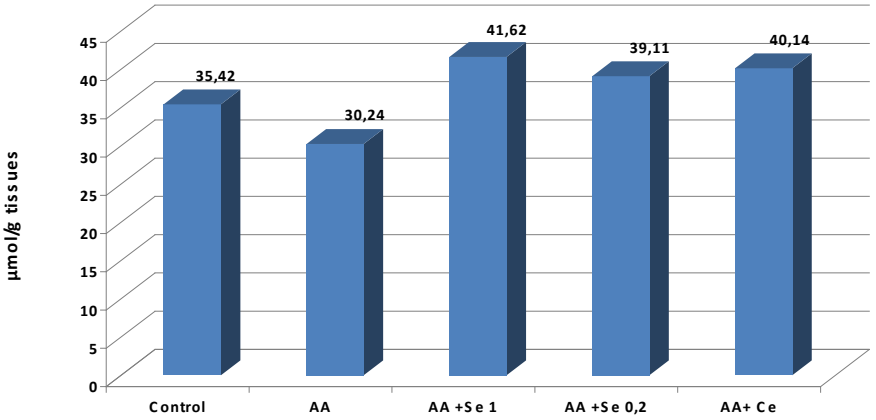

Fig. 2. The values of GSH in liver homogenate

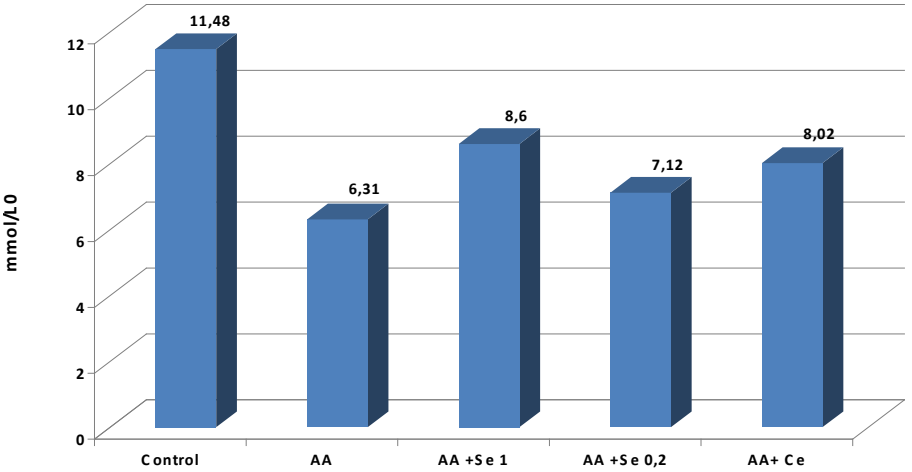

Fig.3. The values of TAS in plasma

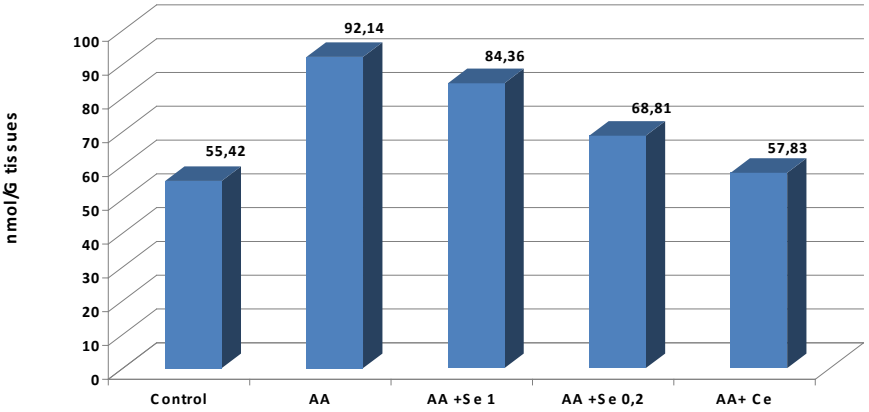

Fig. 4. The values of MDA in liver homogenate

Glutathion peroxidase levels significantly decrease when compared all groups that received AA to control group, sugesting that acrylamide triggers the decrease of the antioxidant defence activity in cell. In groups that received acrylamide alone or with different dose of selenium the most severe decay is observed in group AA. Within groups that received selenium (AA+ Se1) there was noticed the smallest decay suggesting that in high dose this element may supply some protection against oxidative aggresion.

Gluthation levels present a significat decrease when compared the AA group to control one suggesting for a significant amount of reactive species that consume that reducing agent.

An unexpected increase was observed when compared all selenium receiving groups with control group. These data might suggest that selenium has an antioxidant activity by itsself, added to the antioxidant gluthation activity.

Total antioxidant status present a significant decrease when compared all groups that received AA to control group. These data suggest that all antioxidant capacity decrease as a consequence of acrylamide administration. The most severe decrease in total antioxidant capacity is found in group AA, in the remaining other groups the decay was less severe. It is suprising that even if GSH registered an increase in group AA+Se1, the total antioxidant capacity decreased.

Malondialdehyde concentrations are, as expected, significantly higher when compared group AA with control. In groups that received different concentration of selenium, generated malondialdehyde varied as follows: the group with the high dose present an increase compared with group which received 0,2 mg/kg/day.

CONCLUSIONS

The present results showed that acrylamide caused disturbances in the oxidative status, enzyme activities and lipid peroxidation; the results show that a 50 mg/kg acrylamide intake in laboratory animals (Wistar rats) resulted in severe perturbation of some biochemical parameters. The simultaneous intake of selenium as sodium selenite or as a dietary supplement (Celnium) partially prevented some of the biochemical changes in rats which received high doses of acrylamide. We may assume that Selenium has a benefical rol in acrylamide intoxication.

Antibiotice S.A. Iaşi
2. Center for Drug Evaluation

EVALUATION OF SOME PHARMACEUTICAL FORMULATIONS OF LISINOPRIL THROUGH DISSOLUTION TESTING (Abstract): **Aim**: Lisinopril is a drug of the angiotensin converting enzyme (ACE) inhibitor class that is primarily used in treatment of hypertension, congestive heart failure, heart attacks and also in preventing renal and retinal complications of diabetes. We compared the dissolution profiles of Lisinopril 20 mg tablets (Antibiotice S.A. Iaşi) and Zestril 20 mg tablets (Astra Zeneca). **Material and method**: Because lisinopril is a third class active substance, we performed dissolution tests in standard media at three pH values: 1.2, 4.5 and 6.8 using the paddle apparatus at 75 rpm. **Results**: Both pharmaceutical formulations present a dissolution percentage more than 85% (Q) of the labeled amount. **Conclusion**: Both pharmaceutical formulations present similar dissolution profile. **Key words**: LISINOPRIL, TABLETS, DISSOLUTION TEST

Lisinopril, a lysine analogue of enalaprilat, is a long-acting angiotensin converting enzyme inhibitor witch differs from captopril by lacking the sulhydril group. Lisinopril, discovered and developed by the Merck Sharp & Dohme Research Laboratories, is indicated for the treatment of hypertension, congestive heart failure heart attacks and also in preventing renal and retinal complications of diabetes (1,2).

According to World Health Organization lisinopril is (s)-1-[1–carboxy-3 phenylpropyl) -L-lysyl]–L-proline dyhydrate (fig. 1) (2).

Lisinopril is a white to off–white crystalline powder. It is soluble in water (1 to 10) and methyl alcohol (1 to 70), but it is practically insoluble in ethyl alcohol, acetone, chloroform and ether. Log P (octanol/water) was reported to be $=1.22$; log P (phosphate buffer 0.1 M, pH 7/octanol) $=10.2\pm0.5$ (25^0C), pKa values 2.5, 4.0, 6.7, 10.1 (25^0C) (2, 3).

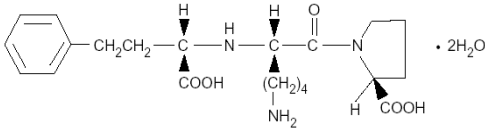

Fig. 1. Lisinopril – chemical structure

Lisinopril can be expected to be "highly soluble" at 37^0C over the entire pH-range 1-7.4. The low bioavailability of lisinopril is in line with its low permeability (2,3,4, 5,6,7,8,9).

Nowadays, the study of dissolution *in vitro* is considered a fundamental requirement in the pharmaceutical industry in order to assure the quality of solid pharmaceutical forms for oral use, guarantee the quality from lot to lot, orientate the development of new formulations and secure the uniformity, quality and performance of the drug even after modifications. On a parallel basis, this allows formulation, optimization in the development phase and, in the same

way, it allows stability studies, manufacturing process monitoring, and the establishment of *in vivo/in vitro* correlations.

The USP 29 dissolution specification for lisinopril tablets is not less than 80% (Q) dissolved in 30 minutes in 900 mL HCl 0.1M (2).

MATERIAL AND METHOD

Dissolution tests were performed according to USP 29 using :

- dissolution tester Erweka DT 808 LH - Apparatus no. 2 (paddle) ;
- medium : - HCl 0.1N, pH 1.2 buffer, pH 4.5 buffer and pH 6.8 buffer ;
- HPLC 1100 Agilent, detector DAD/ MWD and fluorescence.

The dissolution profile of the pharmaceutical formulations was studied using various dissolution medias. First, the comparative dissolution profiles of the drugs were performed using USP dissolution media (HCl 0.1N) at stirring speed of 50 rpm, then the dissolution profiles were obtained using three different dissolution media : pH 1.2 buffer, pH 4.5 buffer and then pH 6.8 buffer at a stirring speed of 75 rpm. The dissolution media volume was maintained at 900 mL in all the cases (3).

Determination of dissolved active substances was performed using a HPLC method. Lisinopril was separated on a C18 column using a mobile phase consisting of a mixture of phosphate buffer pH 2 containing 0.125% sodium hexanesulphonate and acetonitrile (72 : 28, v/v), at a flow rate of 1 mL/ min. Detection was performed at 215 nm on an Agilent 1200 HPLC system. The injection volume was 20 μL. In these chromatographic conditions, the retention time of lisinopril was 1.9 min.

RESULTS AND DISCUSIONS

Comparative dissolution profile of Lisinopril 20 mg tablets produced by Antibiotice S.A. Iaşi (A) and Zestril 20 mg tablets produced by Astra Zeneca (B) gave the results shown in tab. I when performed accordingly to USP 29. The results show that both products have similar dissolution profile as it can also be seen from the graphical representation in fig. 2.

While comparing dissolution profile of the pharmaceutical formulations with lisinopril using 900 mL pH 1.2 buffer as disso-

lution media and stirring speed of 75 rpm, the results shown in tab. II prove that both products released more than 85 % within 15 min. of testing and that they have similar dissolution profiles. This can also be observed from fig. 3.

Each lisinopril product released a percent greater than 90% when tested in a pH 4.5 buffer as dissolution media and at stirring speed of 75 rpm. The percent increases when the released lisinopril is quantified after 30 min. – over 98%. The results are shown in tab. III and they are graphically represented in fig. 4.

The last dissolution test was performed at an almost neutral pH value (pH 6.8 buffer

TABLE IV

Dissolution Test in pH 6.8 dissolution media

% released lisinopril				
Time (min)	10	15	20	30
A	87.1772	93.5230	94.1995	98.3643
B	93.1250	95.2389	95.9041	100.1474

was used as dissolution media). Both products released more than 85% lisinopril in the first 15 min. as it can be seen from tab. IV and fig. 5.

The dissolution rate for both products was over 85 % in 15 min. when testing their dissolution profiles at different pH values, thus it was not necessary to calculate the similarity factors.

CONCLUSIONS

Our studies led to the following results : both products present a dissolution percentage more than 85% (Q) of the labeled amount after 30 min. for lisinopril. The dissolution profiles of the studied products are almost identical.

The products develop similar dissolution profiles, thus the bioequivalence of Lisinopril 20 mg tablets (Antibiotice S.A. Iaşi) and Zestril 20 mg tablets (Astra Zeneca) was demonstrate *in vitro*.

ORDINARY DIFFERENTIAL EQUATIONS WITH APPLICATIONS IN MOLECULAR BIOLOGY (Abstract): Differential equations are of basic importance in molecular biology mathematics because many biological laws and relations appear mathematically in the form of a differential equation . In this article we presented some applications of mathematical models represented by ordinary differential equations in molecular biology. **Material and method**s: The vast majority of quantitative models in cell and molecular biology are formulated in terms of ordinary differential equations for the time evolution of concentrations of molecular species. Assuming that the diffusion in the cell is high enough to make the spatial distribution of molecules homogenous, these equations describe systems with many participating molecules of each kind. **Results:**We propose an original mathematical model with small parameter for biological phospholipid pathway. All the equations system includes small parameter ε.The smallness of ε is relative to the size of the solution domain. If we reduce the size of the solution region the same small ε will result in a different condition number. It is clear that the solution for a smaller region is less difficult.We introduce the mathematical technique known as boundary function method for singular perturbation system. In this system, the small parameter is an asymptotic variable, different from the independent variable. In general, the solutions of such equations exhibit multiscale phenomena. Singularly perturbed problems form a special class of problems containing a small parameter which may tend to zero. **Conclusions:** Many molecular biology processes can be quantitatively characterized by ordinary differential equations. Mathematical cell biology is a very active and fast growing interdisciplinary area in which mathematical concepts, techniques, and models are applied to a variety of problems in developmental medicine and bioengineering. Among the different modeling approaches, ordinary differential equations (ODE) are particularly important and have led to significant advances. Ordinary differential equations are used to model biological processes on various levels ranging from DNA molecules or biosynthesis phospholipids on the cellular level. **Key words:** MOLECULAR BIOLOGY, DNA MOLECULE, PHOSPHOLIPID, DIFFERENTIAL EQUATIONS

Ordinary differential equations (ODEs), especially systems of (ODEs), have been applied in many felds such as molecular biology, medicine, bioengineering. Mathematical and theoretical biology is an interdisciplinary scientific research field with a range of applications in molecular biology. Finding and interpreting the solutions of

these differential equations is therefore a central part of applied mathematics, and a thorough understanding of differential equations is essential for any applied mathematician. In order to do this, precise mathematical models are required. By describing the systems in a quantitative manner, their behavior can be better simulated, and hence properties can be predicted that might not be evident to the experimenter. In order to get a quantitative understanding of a given molecular biology process,it is necessary to come up with a mathematical description of the processwe have in mind. If we want to solve an moleculaer biology problem, we first have to formulate the problem as a mathematical expression in terms of variables, functions, equations Such an expression is known as a mathematical model of the given problem. Give such a mathematical model, we have to analyze it in order to gain some understanding. The above rules are usually in terms of mathematics. They are called mathematical models. One important such models is the ordinary differential equations. It describes relations between variables and their derivatives. Such models appear everywhere [1].

Molecular set theory was introduced by Anthony Bartholomay, and its applications were developed in mathematical biology and especially in Mathematical Medicine. Molecular set theory (MST) is a mathematical formulation of the wide-sense chemical kinetics of biomolecular reactions in terms of sets of molecules and their chemical transformations represented by set-theoretical mappings between molecular sets. In a more general sense, (MST) is the theory of molecular categories defined as categories of molecular sets and their chemical transformations represented as set-theoretical mappings of molecular sets. However, it is usually difficult for people to choose a suitable model structure without sufficient domain details and human expertise, and the determination of parameters also requires the modeler have rich mathematical knowledge and professional skills.

MATERIALS AND METHODS

A remarkable development in molecular biology has been the recent upscaling to the genomic level of its experimental methods. These methods produce, on a routine basis, enormous amounts of data on different aspects of the cell. A large part of the experimental data available today concern genetic regulatory networks underlying the functioning and differentiation of cells. The miniaturization of techniques for the hybridization of labeled nucleic acids in solution to DNA molecules attached to a surface has given rise to DNA microarrays, tools for measuring the level of gene expression in a massively parallel way. The development of proteomic methods based on two-dimensional gel electrophoresis, mass spectrometry, and the double-hybrid system allows the identification of proteins and their interactions on a genomic scale [2]. We give the example of a simple genetic regulatory network, composed of two genes x and y, the proteins X and Y, and their regulatory interactions. An ordinary differential equation model of the network is:

$$(1)\quad \begin{cases} \dfrac{dx}{dt} = \alpha_1 f(y, \beta_2, \chi_2) - u_1 x \\ \dfrac{dy}{dt} = \alpha_2 f(x, \beta_1, \chi_1) - u_2 y \\ f(a, \beta, \chi) = \dfrac{\beta^\chi}{a^\chi + \beta^\chi} \end{cases}$$

where: the variables x and y correspond to the concentrations of proteins X and

Y, respectively parameters α_1 and α_2 to the synthesis rates of the proteins, parameters u_1 and u_2 to the degradation constants , parameters β_1 and β_2 to the threshold concentrations and parameters γ_1 and γ_2 to the degree of cooperativity of the interactions. All parameters are positive . The temporal derivative of x is the difference between the synthesis term $\alpha_1 f(y, \beta_2, \chi_2)$ and the degradation term $u_1 x$. The first term expresses that the rate of synthesis of protein X depends on the concentration of protein Y and is described by the function f. This so called Hill function is monotonically decreasing. The synthesis term $\alpha_1 f(y, \beta_2, \chi_2)$ thus means that, for low concentrations of protein Y, gene x is expressed at a rate close to its maximum rate α_1, whereas for high concentrations of Y, the expression of the gene is almost completely repressed. The second term of the differential equation, the degradation term, expresses that the degradation rate of protein X is proportional to its own concentration x, y being a degradation parameter ($u_1 > 0$). In other words, the degradation of the protein is not regulated in this example. The differential equation for y has an analogous interpretation.

Many mathematical models, including the ones arising is such important areas as cell biology, biochemistry, bioengineering have to include the concentrations of many "intermediate" reactants that are very hard to measure experimentally and many unknown constants (reaction rates) that can not be predicted theoretically with enough accuracy.

For example, the following system of nonlinear ODEs has been used to model the signal transduction and second messenger systems in cell biology. Second messengers are molecules that relay signals from receptors on the cell surface to target molecules inside the cell, in the cytoplasm or nucleus. They relay the signals of hormones like epinephrine (adrenalin), growth factors, and others, and cause some kind of change in the activity of the cell. There are several different secondary messenger systems, but they all are quite similar in overall mechanism, though the substances involved in those mechanisms and effects are different [3].

An ordinary differential equation model is:

$$(2)\quad \begin{cases} \dfrac{dx}{dt} = a(b_0 + b_1 u)(1-x) - \dfrac{\alpha_1 x^4}{\alpha_2^4 + x^4} \\ \dfrac{dy}{dt} = k_1 P y + k_{-1} z \\ \dfrac{dz}{dt} = -(k_{-1} + k_2 x) z + k_1 P y + k_{-2} u \\ \dfrac{du}{dt} = k_2 x z + k_{-3} w - (k_{-2} + k_3 x) u \\ \dfrac{dw}{dt} = k_3 x u - k_{-3} w \end{cases}$$

where: a, b_0, b_1, α_1, α_2, and P are various parameters, such as reaction rates. The variables x, y, z, u, w correspond to the concentrations of agonist activates membrane bound receptor, G-protein activated, G-protein produces effector, effector stimulates second messenger synthesis and second messenger activates intercellular process.

The main structural component of biological membranes are the phospholipids.

The biosynthesis phospholipids depends on the syntesis of diacylglycerol.We have conducted the experiment on the data of a metabolic network that consists of three substances. This target network is a part of the biological phospholipid pathway. Biological processes are often represented in form of networks such as protein-protein interaction networks and metabolic pathways [4]. Mathematical models of molecular biology systems are often formulated as a large set of differential equations with small parameter. When small singular perturbation parameters of the same order of magnitude are present in the dynamic model of a molecular system, the control problem is usually solved as a single parameter perturbation problem, such a system is called a singularly perturbed system.

RESULTS

We analyze an original singularly perturbed system of ordinary differential equations for the model discussed in Tomita [5]. We have conducted the experiment on the data of a metabolic network that consists of three substances. This target network is a part of the biological phospholipid pathway.This network can be approximated as:

$$(P_\varepsilon)\begin{cases}\varepsilon\dfrac{dx}{dt}=-xz\\ \varepsilon\dfrac{dy}{dz}=xz-\varepsilon k_2 y\\ \varepsilon\dfrac{dz}{dt}=-xz+\varepsilon k_2 y\end{cases}$$

with initial conditions: $$(3)\begin{cases}x(0)=x_0\\ y(0)=y_0\\ z(0)=z_0\end{cases}$$

We work on the assumption that $\dfrac{1}{\varepsilon}$, rate from reaction is long, where ε is the small parameter. Note that the parameter k_2 are known for the simulation experiment .The use of a small parameter here is simply for definiteness. For example, a problem depending on a large parameter θ can be rewritten as one depending on a small parameter: $\varepsilon=\dfrac{1}{\theta}$. Equation (P_ε) corresponds to the extended model. Let us now give some formal explications: the terms containing small parameter ε are called perturbations. The extended model (P_ε) is then called perturbed.

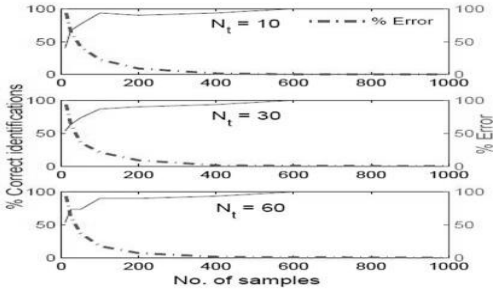

Fig. 1. Variation of correct identifications and identification errors with experimental samples and discretization. The variations are with respect to the number of experimental samples chosen and the number of discretizations, N_t. The "experimental" data are obtained by simulation using the synthetic network.

In this article, the model is formulated in terms of differential equations with small parameter multiplying the highest derivates.Simplified model to consider:

$$(4)(P_0)xz=0$$

Simplified model (P_0) is called unperturbed. Equation (P_0) might be a simplified model of this process. We started out with three differential equations, and ended up saying that one of the differential equa-

tions degenerates to an algebraic equation. A system of three differential equations is quite different from a single differential equation with an algebraic constraint. Unfortunately, in most cases when we change the parameters of the equations to move from one regime to another, the type of the equation changes as well and the solutions in different regimes are often dramatically different. On biological grounds, such as adimensionalisation , we expect that when this parameter reaches certain critical value (usually 0) the system would change its main characteristics which then would make it more amenable to a description at a different level. In this case ,when the coefficient of the highest derivative can take an arbitrary small value in $(0,1]$, the solution of (P_ε) may have limited smoothness. The derivative s of such solutions may increase without bound then the small parameter ε tends to zero.Singularly perturbed problems appear in any area of biology and can be approached by many techniques. Is classical asymptotic analysis based on expansion of the solution in series of powers of the parameter.As we see, three part of (P_ε) contains the small parameter multiplying the derivate. We use the notation $x(t,\varepsilon), y(t,\varepsilon)$ for the solution of (P_ε) and (3). The choice of a small parameter is connected with the order of the solution and the asymptotic sequence which describes the behaviour of the solution as $\varepsilon \to 0$. The overall procedure for work is [6]:

- Develop an appropriate scaling for the equations. Identify the small parameter.
- Writting regular series.
- Writting boundary function series.
- Match up the two solutions in an intermediate time range.

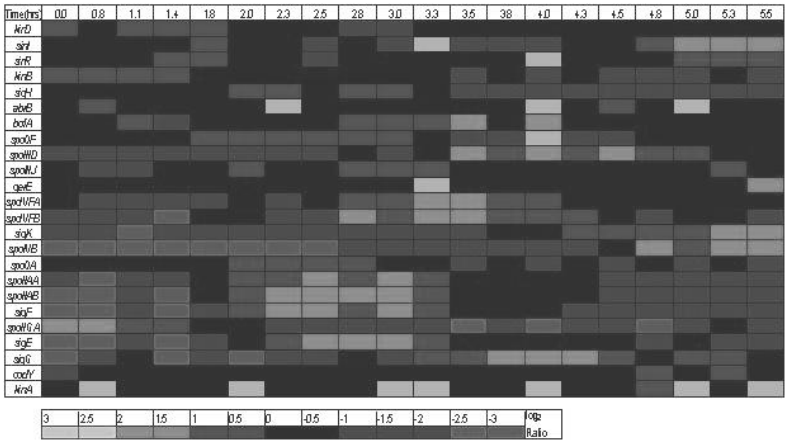

Fig. 2. The time-course (in hours) variation of the logarithm of expression ratios in color-coded format (green indicates up-regulation, red indicates down-regulation, grey indicates missing data and the intensity of the color indicates the level of regulation) of 24 important genes in the population cascade of *B. Anthracis.* An approximate measure of the intensity of the color to the magnitude of the $\log_2$ ratio (fold change) is also given. Note that the ratio refers to that of the actual expression value to the expression value at the reference state.

We will seek the asymptotic expansions for the solution of (P_ε) and (3) in a format that is quite typical for singularly perturbed problems:

$$(5)\quad \begin{cases} x(t,\varepsilon)=\sum_{i=0}^{2}(x^i+\pi_i x)\varepsilon^i+O(\varepsilon^3) \\ y(t,\varepsilon)=\sum_{i=0}^{2}(y^i+\pi_i y)\varepsilon^i+O(\varepsilon^3) \end{cases}$$

where : $\tau=\frac{t}{\varepsilon}$,deals with systems with clear separation of time-scale, $\sum_{i=0}^{2}x^i\varepsilon^i$ is regular series and $\sum_{i=0}^{2}\pi_i x\varepsilon^i$ is boundary function series. Recall that the functions $\pi_0 x,\pi_0 y,\pi_1 x,\pi_1 y$ should be boundary functions, they should approach zero as $\tau\to\infty$. The functions $\pi_0(\tau),\pi_1(\tau)$ decay exponentially as τ increases . Therefore they are important only in a small vicinity of the initial point $t=0$ For $t>>\theta$, where θ is an arbitrarily small, $\pi_k(\tau)\to 0$ as $\varepsilon\to 0$, faster any power of ε . Let is try to construct an asymptotic expansions of the solution of (P_ε), in the form of power series in the power of ε .Series (5) satisfies formally the differential system (P_ε) , but it does not in general satisfy the initial condition (3).

$$(6)\quad \frac{d\pi x}{dt}=\frac{d\pi x}{d\tau}\frac{d\tau}{dt}=\frac{1}{\varepsilon}\frac{d\pi x}{d\tau}$$

If we add the last two equations we obtain system:

$$(7)\begin{cases} \varepsilon\frac{dx}{dt}=-xz \\ \varepsilon\frac{d(y+z)}{dt}=0 \end{cases}\leftrightarrow\begin{cases} \varepsilon\frac{dx}{dt}=-xz \\ y+z=c, c\in\Re \end{cases}$$

CONCLUSIONS

Mathematical model is a representation of the essential aspects of an existing system which presents knowledge of that system in usable form. The use of mathematical models in molecular biology is at once both familiar and arcane. This kind of modeling is done by differential equations. Ordinary differential equations play an important role in the modeling of many real-world processes. What we have looked in this article is a collection of some of the ordinary differential equation models in molecular biology. Mechanistic models in molecular can be regarded as some form of dynamical system. A dynamical system describes the states of a molecular system and how these states change in time. Dynamical systems usually depend on parameters. The temporal dynamics are then described by ordinary differential equations. The classical modeling strategy in molecular biology the ordinary differential equation approach contains three initial phases, and starts with this kind of structural model, in which the reactions and effectors are known. The parameter values have highs impact on the accuracy of the model in representing real biological systems but these values are difficult to estimate experimentally.

RESEARCHES REGARDING THE IMPROVEMENT OF ACYLATION CONDITIONS IN ANTISTAPHYLOCOCCAL PENICILLINS SYNTHESIS (Abstract): **Aim**: The 6-aminopenicillanic acid acylation with certain acyl chlorides was performed in order to obtain antistaphylococcal penicillins with bigger crystals, easy to filtrate (shorter filtration time), much pure, and an increased output. **Material and methods**: Oxacillin sodium salt was synthesized by acylating an aqueous solution of 6-aminopenicillanic acid sodium salt ($NaHCO_3$ not in excess) with an ethylacetate solution of 5-phenyl-3-methyl-isoxazolyl-4-carboxilic acid chloride. The crystallization was performed with a 40.5% sodium 2-ethyl hexanoate izopropanolic solution. All tests (IR spectrum, iodometric titration, and microbiological dosage) were performed according to the Xth Romanian Pharmacopoeia standards. **Results**: The amount of synthesized oxacillin was higher and the output of 88,21%. Oxacillin had a high chemical purity (98,72%), and a very good microbiological activity (95% of the standard activity). **Conclusions**: Oxacillin crystals were bigger, the filtration speed was increased, and process efficacy improved. The output of the process was also improved being higher than with classical acylation. **Key words:** ACYLATION, PENICILLINS, BETA-LACTAMS

Oxacilina sodică se produce la SC Antibiotice SA sub formă de capsule pentru administrare orală şi flacoane cu pulbere injectabilă pentru administrare parenterală.

Metoda actuală de obţinere a oxacilinei sodice presupune acilarea mol la mol a sării de sodiu a acidului 6-aminopenicilanic (6-AP) cu clorura acidului 3-fenil-5-metil-4-izoxazolilcarboxilic în prezenţa unui exces de bicarbonat de sodiu, în mediu hidro-acetonic (1, 2, 3). Ulterior, se supune cristalizării oxacilina ca acid din soluţie anhidră de acetat de butil cu o soluţie izopropanolică de 2-etilhexanoat de sodiu (2-EH Na). Se obţin astfel cristale mici de oxacilină sodică, ceea ce face ca procesul de filtrare al unei şarje de oxacilină să dureze foarte mult (aproximativ 8 ore). Pe parcursul acestui timp, oxacilina sodică se poate degrada parţial datorită expunerii la umiditatea atmosferică.

Pe lângă aceste două inconveniente ale

procesului industrial (timp mare de filtrare şi posibilitatea degradării parţiale a oxacilinei sodice), mai există unul şi anume, un randament total mediu de 74-80%.

Ţinând cont de aceste date, în acest studiu am încercat să îmbunătăţim procesul de obţinere în ceea ce priveşte mediul şi condiţiile de reacţie. În acest fel dorim să obţinem un randament superior şi cristale mai mari de oxacilină sodică, adică uşor filtrabile, pentru a avea un timp de filtrare mai scurt.

MATERIAL ŞI METODĂ

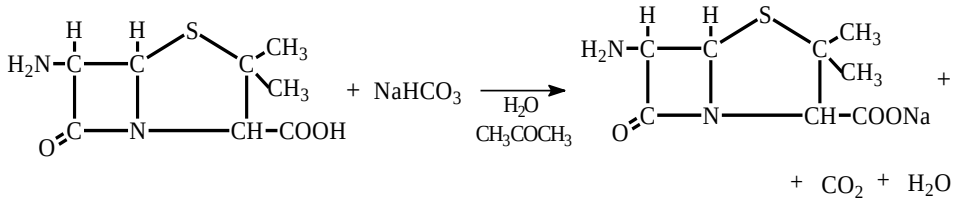
În acest studiu am încercat să obţinem oxacilina sodică sub formă de cristale uşor filtrabile realizând reacţia de acilare în solvenţi diferiţi, utilizând un mic exces de acid 6-AP (0,001 moli), iar bicarbonatul de sodiu fiind adăugat în acelaşi procent molar cu acidul 6-AP.

S-au realizat 3 variante:

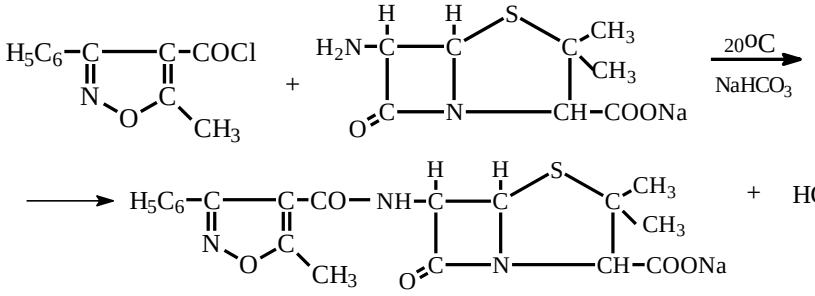
1. solubilizarea acidului 6-AP într-un amestec de apă-acetonă, fără exces de bicarbonat şi adăugarea clorurii acide dizolvată în diclormetan (DCM);
2. solubilizarea acidului 6-AP în apă, fără exces de bicarbonat şi adăugarea clorurii acide dizolvată în DCM;
3. solubilizarea acidului 6-AP în apă, fără exces de bicarbonat şi adăugarea clorurii acide dizolvată în acetat de etil.

Chimismul reacţiilor, pentru toate cele 3 variante, este următorul:

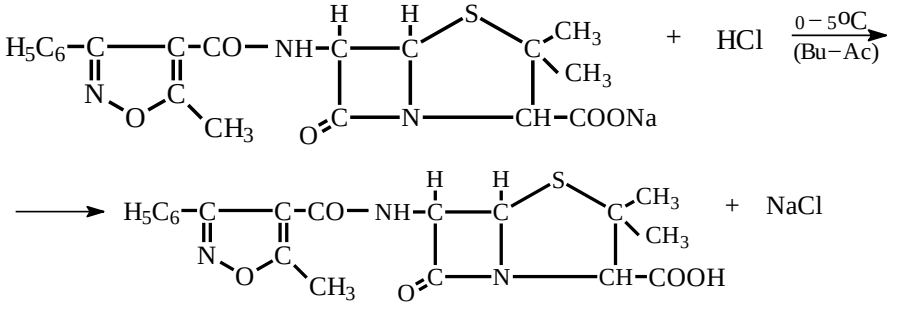
1.

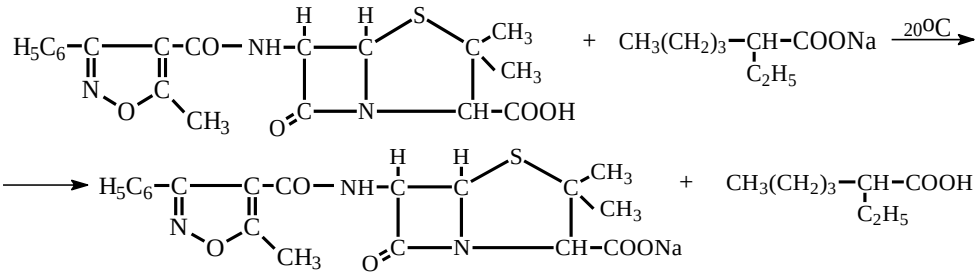


2.



3.





Modul de lucru este asemănător pentru toate cele 3 variante, diferind solvenţii, cantităţile şi condiţiile de lucru.

Se solubilizează 0,018 moli (4 g) de acid 6-AP cu 0,018 moli de $NaHCO_3$ într-un amestec de 60 ml apă:acetonă (1:1), respectiv 60 ml apă pentru variantele B şi C. Se agită continuu până la solubilizarea acidului 6-AP (aproximativ 0,5 ore). Soluţia obţinută, cu un pH=7, se răceşte pe baia de gheaţă la 0-5^{0}C. Sub agitare energică şi continuă se adaugă 0,017 moli (3,90 g) de clorură a acidului 3-fenil-5-metil-4-izoxazolilcarboxilic dizolvată în 45 ml de DCM, respectiv 45 ml de acetat de etil pentru varianta C. Adăugarea soluţiei organice a clorurii acide se realizează în aproximativ 45 min., astfel încât temperatura să nu depăşească 5^{0}C. Reacţia se perfectează 2,5-3 ore sub agitare energică şi continuă, la temperatura de 5-10^{0}C. Se lucrează folosind un mic exces de acid 6-AP (0,001 moli). Ulterior, se separă stratul hidro-acetonic superior în care se găseşte oxacilina ca sare de sodiu.

Soluţiei hidro-acetonice de oxacilină sodică i se adaugă 70 ml acetat de butil, se răceşte amestecul la 0-5^{0}C şi, sub agitare energică, se adaugă cât mai repede o soluţie de HCl 18% până la pH=1,8-2. Într-o pâlnie de separare se separă faza organică superioară ce conţine oxacilina ca acid. Faza organică se anhidrizează cu Na_2SO_4 anhidru şi se supune cristalizării cu o soluţie izopropanolică de 2-EH Na, de concentraţie 40,5% (2,98 g 2-EH Na, 0,018 moli, 7,7 ml), la temperatura camerei. Cristalizarea este greoaie, iar primele cristale apar după 1,5 ore. După perfectarea cristalizării (3 ore), se separă oxacilina sodică prin filtrare, se spală direct pe filtru cu butanol şi apoi cu acetonă şi se usucă sub vid. Cristalele sunt destul de mari, astfel încât filtrarea decurge uşor.

S-au realizat spectrele IR cu ajutorul unui spectrofotometru Specord 71 IR Carl Ziss-Jena, în domeniul 200 cm^{-1} - 4000 cm^{-1}. S-a comprimat prin pastilare un amestec ce conţine 1-3 mg oxacilină sodică şi 0,3 g bromură de potasiu (R) (4). Spectrele oxacilinei sodice, preparată prin cele trei variante, au fost comparate cu spectrul IR al oxacilinei standard de fabrică (S.C. Antibiotice S.A.). S-a realizat şi determinarea cantitativă a oxacilinei prin metoda volumetrică (titrare iodometrică) şi dozarea microbiologică prin metoda difuzimetrică în agar, conform prevederilor din Farmacopeea Română ediţia X (FR X) de la determinarea cantitativă a oxacilinei (5). S-a utilizat mediul V recomandat de FR X, microorganismul test utilizat a fost *Staphylococcus aureus* ATCC 6538P, iar ca diluant pentru prepararea soluţiilor de antibiotic s-a folosit soluţia de tampon fosfat pH=7. Ca standard s-a utilizat oxacilina sodică, standard de fabrică al S.C. Antibio-

tice S.A. Iaşi, cu activitatea microbiologică de 851,22 µg oxacilină/mg. Plăcile Petri se inoculează şi se incubează la termostat 18 ore la 35-37^{0}C, după care se măsoară şi se înegistrează zonele de inhibiţie, urmând să se calculeze media aritmetică a diametrelor zonelor de inhibiţie conform recomandărilor din FR X (5).

REZULTATE ŞI DISCUŢII

Pentru fiecare variantă s-au realizat 5 determinări. Cantităţile de oxacilină sodică şi media determinărilor sunt redate în tabelul I.

TABELUL I

Cantităţile de oxacilină sodică obţinute în cele trei variante de preparare

Metoda	Cantitatea obţinută (g)					
	1	2	3	4	5	Media determinărilor
Varianta A	5,86	6,06	5,99	5,98	6,24	6,02 g
Varianta B	6,86	6,79	6,59	6,76	6,54	6,70 g
Varianta C	7,18	7,15	7,25	7,21	7,20	7,04 g

Din datele obţinute se observă că cele mai mari cantităţi de oxacilină sodică s-au obţinut utilizând varianta C (acilarea în apă-acetat de etil, fără exces de bicarbonat).

S-au calculat randamentele pentru cele trei variante de preparare, rezultatele fiind trecute în tabelul II.

TABELUL II

Randamentele de obţinere a oxacilinei sodice în cele trei variante de preparare

Metoda	Randamentul (%)					
	1	2	3	4	5	Media determinărilor
Varianta A	71,83	74,26	73,40	73,28	76,47	73,84 %
Varianta B	84,06	83,21	80,75	82,84	80,14	82,20 %
Varianta C	87,99	87,62	88,84	88,35	88,23	88,21 %

Se observă că varianta C de obţinere a oxacilinei sodice are cele mai mari randamente (87-88 %). Se poate spune că prepararea oxacilinei sodice este mai avantajoasă folosind varianta C (acilarea în apă-acetat de etil, fără exces de bicarbonat) întrucât se obţin cantităţi mai mari de oxacilină sodică, respectiv randamente de producţie mai mari, iar filtrarea oxacilinei se realizează mult mai uşor.

Oxacilina sodică obţinută prin cele 3 variante se prezintă sub formă de pulbere cristalină albă, fără miros, cu gust slab amar, uşor solubilă în apă şi practic insolubilă în acetonă, eter şi cloroform.

Oxacilina sodică obţinută prin cele trei variante are spectre IR comparabile cu cel al standardului de fabrică. În cazul standardului se observă un maxim de absorbţie la 1760 cm^{-1} ce este caracteristic vibraţiilor legăturii carbonilice lactamice (=C=0) şi un maxim de absorbţie la 1580 cm^{-1} ce este caracteristic vibraţiilor legăturii amidice (-CO-NH-) din catena laterală (4). În cazul

celor trei probe de oxacilină sodică se observă că maximele de absorbţie corespunzătoare legăturii lactamice sunt la 1770 cm^{-1}, 1773 cm^{-1} şi respectiv, 1765 cm^{-1}. Maximele de absorbţie corespunzătoare legăturii amidice sunt la 1584 cm^{-1}, 1589 cm^{-1} şi respectiv, 1582 cm^{-1}. Datele sunt prezentate în tabelul III.

TABELUL III

Caracteristicile spectrale ale oxacilinei sodice obţinută prin cele trei variante de preparare şi ale standardului de fabrică

Oxacilina sodică	Frecvenţa caracteristică (cm^{-1})	
	(=C=O) lactamică	(-CO-NH-)din catena laterală
Varianta A	1770	1584
Varianta B	1773	1589
Varianta C	1765	1582
Standard de fabrică	1760	1580

Determinarea cantitativă s-a realizat prin titrare iodometrică, cele trei probe de oxacilină sodică având purităţi ce sunt redate în tab. IV. Pentru a corespunde prevederilor din FR X, oxacilina sodică trebuie să conţină cel puţin 90% şi cel mult 100,5% peniciline totale exprimate în $C_{19}H_{18}N_3NaO_5S \cdot H_2O$ (5). Se observă că oxacilina sodică obţinută prin varianta C are cea mai mare puritate (98,72%).

TABELUL IV

Concentraţia probelor de oxacilină sodică

Nr. crt.	Oxacilina sodică	Concentraţia (g%)
1.	Varianta A	90,23
2.	Varianta B	93,51
3.	Varianta C	98,72

În urma dozării microbiologice s-au obţinut rezultatele redate în tab. V. Proba este corespunzătoare dacă activitatea ei microbiologică reprezintă cel puţin 90,0% şi cel mult 110,0% din activitatea microbiologică a standardului utilizat (5). Se observă că din toate probele analizate, doar cea a oxacilinei sodice obţinută prin varianta C corespunde prevederilor, având o activitate microbiologică de 95,00% din activitatea standardului.

TABELUL V

Activitatea microbiologică a oxacilinei sodice

Nr. crt.	Oxacilina sodică	Activitatea microbiologică (µg/mg)	Activitatea microbiologică faţă de standard (%)
1.	Varianta A	751,6	88,29
2.	Varianta B	759,3	89,20
3.	Varianta C	808,7	95,00
4.	Standard de fabrică	851,22	-

CONCLUZII

Obţinerea oxacilinei sodice prin metoda aplicată în acest studiu (acilarea în apă-acetat de etil utilizând un mic exces de acid 6-AP şi adăugarea bicarbonatului de sodiu în acelaşi procent molar cu acidul 6-AP) este mai avantajoasă decât metoda clasică, întrucât din modul de lucru dispare o etapă de extracţie (luând un exces de acid 6-AP nu mai trebuie realizată extracţia pentru îndepărtarea clorurii acide nereacţionate).

La finalul sintezei se obţin cristale de oxacilină sodică mari, uşor filtrabile, a căror filtrare se realizează într-un timp mai scurt, dispărând posibilitatea degradării antibioticului pe parcursul filtrării. Această cristalizare este mai bună dacă oxacilina sodică se obţine prin varianta C.

Aceeaşi variantă C permite obţinerea unor cantităţi mai mari de oxacilină sodică (7,04 g), procesul decurgând cu randamente superioare (88,21%).

Analiza calitativă a evidenţiat că probele de oxacilină sodică obţinute corespund standardului, iar analiza cantitativă a relevat că oxacilina sodică obţinută prin varianta C are o puritate chimică mare (98,72%) şi o activitate microbiologică mare (95% din activitatea standardului).

În concluzie, oxacilina sodică se obţine cu randamente superioare şi timp de filtrare mult mai scurt, dacă sinteza se realizează prin acilarea acidului 6-AP, solubilizat ca sare de sodiu în apă, cu o soluţie în acetat de etil a clorurii acidului 3-fenil-5-metil-4-izoxazolilcarboxilic, acilare realizată la 0-5^{0}C timp de aproximativ 3 ore. Cristalizarea oxacilinei se realizează din soluţia organică anhidră a oxacilinei ca acid cu o soluţie izopropanolică de 2-etil hexanoat de sodiu.

COMMUNITY PHARMACY – IDEAL LOCATION TO SCREEN AND MONITOR HYPERTENSIVE PATIENTS (Abstract): The goals of this study were (a) to create a patient electronic database by filling in the specially designed Patient Data Sheets (PDS) after interviewing hypertensive patients and (b) to evaluate pharmacists' opportunities for intervention in order to improve hypertensive patients' outcomes. **Material and method**: Pharmacists from two Romanian chain community pharmacies interviewed all hypertensive patients that entered the pharmacies during the study period (November – December 2008) and selected 106 subjects using several selection criteria. Pharmacists recorded in specially designed Patient Data Sheet relevant information such as: demographic data, additional diagnostics (if any), lifestyle behaviors and therapeutic data. The records were then transferred into an electronic database and interpreted by the research team. **Results**: Hypertension (HT) as a single disease was present in only 7 patients (6.6%), most of them being diagnosed with multiple illnesses (such as HT and cardiovascular disease (CVD) in 25 patients, HT and dyslipidemia (DL) in 20 patients). More than half of the subjects (61.3%) declared they have adopted at least one lifestyle modification component and almost 80% of the patients use two, three or more antihypertensive agents in their medication. **Conclusions**: The high incidence of complications among our hypertensive subjects justifies implementing blood pressure monitoring programs in community pharmacies and requires pharmacists' intervention for a better management of hypertension. **Key words**: HYPERTENSION, PATIENT DATA SHEET, LIFESTYLE MODIFICATIONS, MONITORING PROGRAMS

Hypertension (HT) is a major healthcare problem in Romania and one of the most frequent causes of cardiovascular morbidity and mortality. It affects people of all ages, social statuses and professions (1) and initially it causes no symptoms. In the case that some symptoms appear, these are of low intensity and non-specific (2).

HT is also the major risk factor for cardiovascular and cerebrovascular diseases, along with other contributing factors such as: dyslipidemia (DL), diabetes mellitus (DM), obesity, unhealthy diet or sedentary lifestyle (3). Major complications remain uncontrolled or poorly controlled for longer periods of time (4,5). Thus, an optimized control on blood pressure (BP) values is needed to reduce the prevalence of complications. BP values are considered "normal" as long as they are below 140/90 mmHg (in case of a patient with DM or chronic renal disease, the upper limit is 130/80 mmHg) (3,6,7) and "optimal" if they are below 120/80 mmHg (7). Based on evidences, it was found that the cardiovascular disease risk doubles with every increase of

20/10 mm Hg above 115/75 mmHg (1).

Although guidelines recommendations stress for early discovery and aggressive treatment of HT, many studies reported low compliance or poor adherence to therapy (8). Consequently, this determines poor control of BP values and high prevalence of complications. The management of HT in society became an important challenge for the healthcare system (5); identifying patients with high BP represents a major challenge for community pharmacists (5,9). Considered as the most accessible healthcare providers (9), community pharmacists are in a unique position to run screening programs (10). The beneficial of these programs is supported by large scale studies (4) because it was found to improve outcomes and compliance (8). Additional services like blood pressure monitoring and short counseling sessions are also proven to increase patient's compliance (1,11).

Some of the most effective non-pharmacological treatment measures consist in lifestyle changes (7). A healthy lifestyle, as pointed out by the Seventh Report of JNC (Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure), can lower BP values and decrease the progression of HT (6) preventing from complications or delaying them (5,6). Lifestyle changes are strongly recommended to hypertensive patients as well as to people having one or more risk factors (6). Community pharmacists have the opportunity to reinforce the importance of lifestyle changing each month a hypertensive patient refills her/his medication (5,12,13). They should also detect and solve potential drug related problems before they generate adverse reactions and reduce compliance to treatment (9).

Pharmacy based HT screening programs for identifying patients at risk for cardiovascular and cerebrovascular diseases have shown their effectiveness as an important percentage of interviewed patients were referred to physicians with high BP values (4). Equally important, monitoring programs for already diagnosed hypertensive patients contribute to a better management of HT, increase patient motivation and adherence to therapy (8,9,10).

This study was conducted according to law 46 and 667 (14,15).

MATERIAL AND METHOD

The rationale of this study was to pilot a methodology for gathering relevant patient information and to test its usefulness for future interventions in hypertensive patients. The goals were (a) to create a patient electronic database by filling in the specially designed Patient Data Sheets (PDS) after interviewing hypertensive patients by the time they refill their medication and (b) to evaluate pharmacists' opportunities for intervention (education, counseling, monitoring) in order to improve hypertensive patients' outcomes.

During the study period (November – December 2008), pharmacists from two chain community pharmacies have interviewed 106 hypertensive patients. Patients selection followed several criteria: (a) diagnosed with HT for more than 1 year, with no major cardiovascular or cerebrovascular event in the last 6 months; (b) they refill regularly their prescriptions for HT medication (all patients are well known to pharmacy staff for long time), therefore the compliance to treatment can be estimated as good; (c) the HT medication they take didn't changed recently.

Community pharmacists participating in the study followed a short training session where they were explained how to correctly fill in the PDS. They recorded in PDS relevant information such as: demographic data, additional diagnostics (if any), adopted lifestyle modifications (if the case) and therapeutic data.

The main outcome measures of this study

were: HT distribution vs. sex and age, prevalence of complications, lifestyle modification components adopted by patients, prescribed therapeutic classes.

Information recorded in PDS were transferred to an electronic database (Excel workbook) and interpreted by following criteria: distribution of diagnostics among interviewed hypertensive patients, patient behaviors and lifestyle, distribution of HT treatment schemes (how many anti-hypertensive drugs were chosen in patient's treatment) and of therapeutic classes.

RESULTS

The interviewed patients (n = 106, 44 men and 62 women) were previously diagnosed with: HT as single disease (7 patients), HT and diabetes mellitus (DM) (6 patients), HT and cardiovascular disease (CVD) (25 patients), HT and dyslipidemia (DL) (20 patients), HT and DL and CVD (35 patients), HT and other chronic diseases (13 patients). The frequency of diagnostics is presented in fig. 1.

Clinical evidences have been shown that, by adopting lifestyle modifications, hypertensive patients may notice significant decrease of blood pressure values and cardiovascular risk (3,6). The most important changes the patients should adopt would include weight loss (in case of overweight patients), reduction of sodium intake, physical activity, moderate alcohol consumption, smoke cessation (6, 7). When additional conditions occur, further measures might be needed: low fat diet for patients with

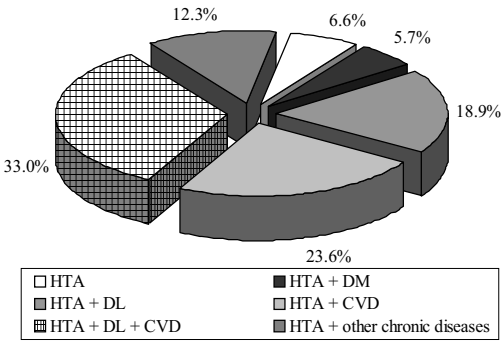

Fig. 1. Frequency of diagnostics at hypertensive patients

DL, low sugar intake for patients with DM.

Sixty-five patients (61.3%) declared they have adopted at least one lifestyle modification component while thirty eight chose to ignore the importance of these measures (fig. 2).

Lifestyle changes that patients in study have adopted are: lowering of sodium intake (57 patients), low fat diet (21 patients), moderation in alcohol consumption (12 patients), weight loss (6 patients), daily physical activity (5 patients) and low sugar diet (5 patients).

When lifestyle modifications cannot reach blood pressure goals, pharmacological treatment is needed. Published studies evidenced that most of the hypertensive patients are treated with more than one antihypertensive agent. The most commonly used medication classes cited by literature are diuretics, beta--blockers, ACE inhibitors, angiotensin II antagonists and calcium channel blockers (6).

Twenty two patients (20.8%) were treated with antihypertensive monotherapy, 45

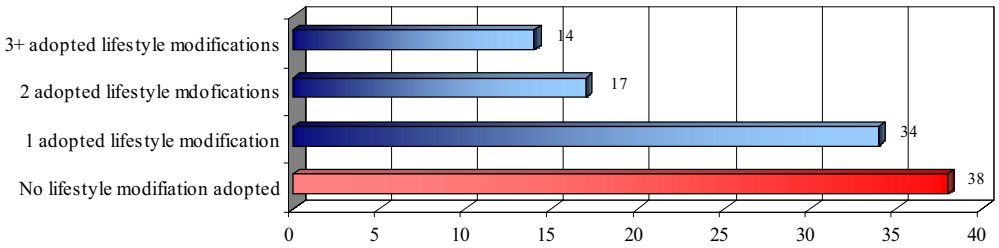

Fig. 2. Patients adopting lifestyle modifications

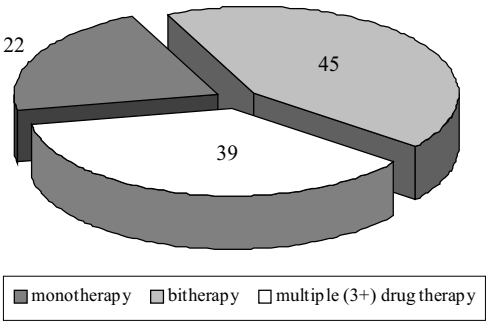

Fig. 3. Pharmacological therapy for hypertension

(42.4%) with bitherapy and 39 (36.8%) with three drugs or even more because of the complications of hypertension (fig. 3).

The most frequently prescribed therapeutic classes were: angiotensin converting enzyme inhibitors (67 patients), diuretics (65 patients) and beta-blockers (60 patients) (fig. 4).

DISCUSSIONS

The hypertensive subjects included in the study were also diagnosed with DM, DL and CVD therefore it should be more useful to have their BP values monitored (in a community pharmacy or by self-monitoring) for a better management of HT. We counted only 7 patients with HT as a single disease, the other 99 patients (93.4%) had additional diseases, most of them classified as risk factors for CVD. Early evaluation of risk factors followed by patient education on dietary regimen, lifestyle changes and pharmacological therapy, would prevent or delay the evolution of complications (7).

The high incidence of complications among our hypertensive subjects justifies implementing BP values monitoring programs in community pharmacies and requires pharmacists' intervention for a better management of HT. In addition, as many of our subjects (36.8%, more than a third) follow a multiple (3+) drug therapy, the probability of drug related problems (DRP) to occur is higher than in other patients. Thus, following programs should also address possible DRP, for the safety of the patients and for a higher, long-term, compliance to treatment.

Behavioral changes that have greater impact on BP values include diet modifications (richer in fruits, vegetables, low-fat products and lower sodium intake), more physical activity and weight loss (5). Although these changes are easy to understand and remember, hypertensive patients have difficulties in applying them over longer time. By involving community pharmacists in supporting patients to maintain a healthier lifestyle, a better control of HT might be achieved (13).

The database we created can be used for future programs where patients shall be closely monitored on how they stick to a healthier lifestyle and follow the treatment

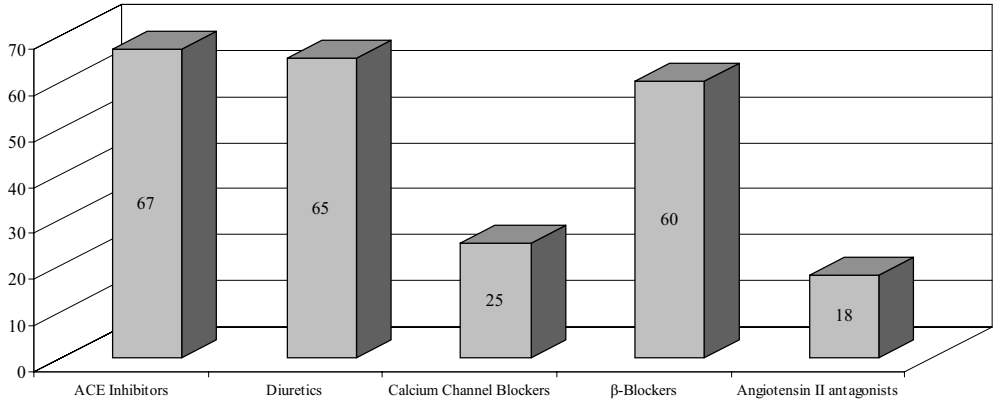

Fig. 4. Antihypertensive therapy – prescribed drug classes

as prescribed. By recording how often patients refill their medication (which medicines are regularly purchased) or if they adjust the dosage on higher/lower BP values (measured with self monitoring devices), pharmacists may evaluate both patient's compliance as well as BP values control. Looking forward, pharmacists may use a quiet space/area in the community pharmacy to measure patient's BP and to perform counseling sessions, as most of the subjects with uncontrolled HT would require closer attention.

The researchers did not aim to screen for uncontrolled BP values on hypertensive patients, therefore BP values were neither recorded nor measured in community pharmacies during this study. The methodology used to build the patient database may be improved by recording additional disease related or treatment related information such as risk factors for HT or CVD, OTC products or natural remedies the patients take on top of their chronic medication.

CONCLUSIONS

HT treatment in Romania follows the most important guidelines recommendations. However, the incidence of complications is extremely high leading to conclusion that HT is poorly controlled. The results of this study suggest that pharmacists can use various intervention strategies like : implementing more lifestyle modifications, BP values monitoring and making patients aware on severity of complications in order to achieve HT treatment goals.

Community pharmacies are some of the most accessible locations to develop pharmaceutical care programs for hypertensive patients due to the fact that community pharmacies are frequently visited by these patients and most of them accept the care and interest that pharmacists show for their medical condition.

NOUTĂŢI

EFECTUL CONDIŢIONĂRII CU EDTA ÎN CAZUL UTILIZĂRII ADEZIVILOR CE CONŢIN ETANOL

Sistemele adezive cu gravaj acid presupun demineralizarea dentinei şi expunerea colagenului care va fi ulterior infiltrat de răşină. Prin demineralizare, aproape 50% din volumul mineral este înlocuit de apă. Pentru a substitui apa cu răşina hidrofugă, adezivii utilizează un solvent hidrofil. În cazul etanolului, timpul necesar pentru a disloca apa este destul de lung şi creşte cu cât demineralizarea este mai profundă. Pentru a scurta tipul operator autorii studiului propun realizarea unui strat hibrid mai subţire şi mai rezistent, prin demineralizarea dentinei cu EDTA. Rezistenţa adeziunii la tensiune, permeabilitatea interfeţei şi modul în care se produce desprinderea la nivelul ei, au fost evaluate pe secţiuni dentinare umede, condiţionate cu acid ortofosforic, respectiv EDTA, pe care s-au aplicat 5 amestecuri experimentale de monomeri şi etanol şi un adeziv comercial. In vitro, s-au efectuat testarea la microtensiune a secţiunilor longitudinale, examinarea interfeţei după fractură utilizând microscopul stereoscopic, microscopul electronic prin scanare şi microscopul electronic confocal prin scanare iar micropermeabilitatea a fost evaluată prin umplerea camerei pulpare cu o soluţie colorată de rodamină B. Cele mai hidrofobe răşini (similare răşinilor aplicate în etapa finală a sistemelor bi- şi tri-componente) au prezentat valorile cele mai mici ale adeziunii la dentina gravată acid iar probele la care aplicarea s-a făcut pe dentină tratată cu EDTA au cedat prematur la testul de rezistenţă la microtensiune. Una dintre răşinile hidrofile acide testate (similară adezivilor autogravanţi), a prezentat cele mai mari valori ale rezistenţei la microtensiune atât la dentina tratată cu EDTA cât şi la probele gravate acid, în timp ce cealaltă a prezentat o infiltrare redusă atunci când a fost aplicată pe dentina gravată acid. Adezivul comercial testat a prezentat valori mai mari atunci când a fost aplicat pe dentina gravată acid decât pe dentina condiţionată cu EDTA. Testul de micropermeabilitate a demonstrat valori mult mai mici pentru probele tratate cu EDTA pentru 4 din cei 6 adezivi testaţi. Este posibil ca EDTA-ul să denatureze într-o măsură mai redusă colagenul expus şi să determine o dentină mai susceptibilă la impregnare. Rezultatele au demonstrat că utilizarea EDTA-ului pentru condiţionare dentinară ar putea constitui o alternativă promiţătoare a gravajului acid în cadrul tehnicii de adeziune în mediu umed cu răşini dizolvate în etanol. Compoziţia chimică a amestecurilor de răşină reprezintă în continuare un factor determinant al capacităţii de adeziune atât la dentina tratată acid cât şi la dentina tratată cu EDTA. Studiile viitoare vor demonstra dacă acest tip de condiţionare determină o hibridizare dentinară mai rezistentă la solicitările din mediu oral, pe termen lung (Sauro S et al. Resin–dentin bonds to EDTA-treated vs. acid-etched dentin using ethanol wet-bonding. *Dent Mat* 2010 ; 26 (4) : 368-379).

COMPARATIVE STUDY OF SOME CLINICAL AND LABORATORY INDICATORS IN A GROUP OF PATIENTS USING WELLS AS SOURCE OF DRINKING WATER AND A CONTROL GROUP USING SAFE WATER (Abstract): In time, well water, as a source of drinking and coking water, with physical-chemical, bacteriological, and biological indicators suggestive of alteration in water potability, determines complex, sometimes irreversible, metabolic disorders. **Material and methods**: Sixty individuals residing in a rural community were divided into 2 groups: study group -30 subjects using well water, and control group - 30 subjects using safe water. For the study group the selection criteria were: age, sex, use of well water as drinking and cooking water, history suggestive of chronic poisoning (pregnancy course, birth weight, susceptibility to infectious agents, and current chronic diseases). **Results**: In the study group, gestosis, prematurity, and altered body mass index are more frequent as compared to the subjects in the control group. The identified laboratory changes indicate moderate anemia, hepatic cytolysis, dyslipidemia, presence of nitrites in urine, and positive urine cultures. **Conclusions**: Long-term use of water with mineral constituents in excess, absent, or inadequate, the direct biological and chemical water pollution, or most frequently the indirect pollution through the soil determine, in time, complex, sometimes irreversible, metabolic disorders. **Key words**: WELL WATER GESTOSIS, ANEMIA, NITRITE POISONING

Apa este un element de mediu esenţial, indispensabil desfăşurării proceselor vitale, cu rol important în menţinerea stării de sănătate, dar şi o cauză posibilă – atunci când calităţile ei sunt afectate – de perturbare a proceselor metabolice.

Studii fiziologice, biochimice, clinice, şi epidemiologice efectuate asupra efectelor produse de poluarea factorilor de mediu, inclusiv a apei potabile, au demonstrat apariţia şi manifestarea mai pregnantă a efectelor nocive ale poluării mediului extern asupra organismelor tinere, care au o reactivitate generală scăzută împotriva acestor agresiuni, datorită stadiului de dezvoltare morfo-funcţional al organismului la vârsta copilăriei (1).

Apa de fântână, ca sursă de apă alimentară, cu indicatori fizici, chimici şi biologici ce indică afectarea potabilităţii apei, determină în timp tulburări metabolice complexe cu repercusiuni importante asupra dezvoltării psiho-somatice normale a organismului. Elementele minerale din apa potabilă (fier,

cupru, zinc, fluor, iod etc.), sunt componente structurale ale celulelor şi lichidelor interstiţiale cu rol important în cataliza enzimatică, asupra permeabilităţii membranare, a echilibrul hidro-electrolitic şi acido-bazic. Indiferent de cantităţile mici necesare zilnic organismului sunt esenţiale pentru organismul deoarece acesta nu le poate sintetiza sau înlocui. Carenţa sau excesul lor în organism, dacă persistă suficient timp, determină tulburări metabolice uneori ireversibile (2).

Îngrăşămintele chimice, biostimulatorii sau antidăunătorii cu biodegradare lentă, folosiţi în agricultură, formează în sol produşii de degradare ce persistă mult timp (pesticidele organo-clorurate, cu plumb, mercur au remanenţă în sol de peste 5 ani), iar potenţial toxic al intermediarilor de descompunere este uneori mai mare decât cel iniţial. Trecând din sol în plante, la animale sau în apa subterană ajung în organism prin consumul acestora (1).

În cazul intoxicaţiilor cu cantităţi mici în intervale lungi de timp, simptomatologia este mai puţin manifestă iar modificări umorale apar tardiv, bineînţeles cu variaţii de intensitate la diferiţii membrii ai colectivităţii expuse. Efectul nociv asupra organismului depinde de cantitatea de toxic ingerată, de structura şi proprietăţile sale fizico-chimice.

Pesticidele organoclorurate, datorită liposolubilităţii pe care o au se absorb digestiv uşor şi pot fi depozitate în ţesutul adipos, astfel încât îşi pot manifesta acţiunea nocivă atât după ingestie cât şi după mobilizarea din ţesuturi(3). Hepato- nefrotoxicitatea, caracterul mutagen şi cancerigen se datorează capacităţii pesticidelor organoclorurate de a fi inductori enzimatici prin care interferează căile metabolice normale; posibilitatea de a traversa membrana placentară şi de eliminare prin secreţia lactată afectează direct produsul de concepţie (3,4).

Nitroderivaţii, ei însăşi, nu prezintă un pericol prea mare pentru organism, dar în mediul înconjurător (apa, sol) sau la nivel intestinal, aceştia sunt transformaţi de unele bacterii în nitriţi. Nitriţii absorbiţi în sânge determină formarea methemoglobinei, cu hipoxie tisulară consecutivă şi afectare metabolică generală (5).

Surprinderea în fază incipientă a modificărilor umorale sugestive intoxicaţiei cronice consecutive consumului apei de fântână face obiectul studiului nostru.

MATERIAL ŞI METODĂ

Studiul a fost realizat pe un lot de 60 subiecţi, dintr-o colectivitate rurală, repartizaţi într-un lot de studiu de 30 subiecţi care folosesc apa de fântână ca sursă de apă potabilă şi un lot martor de 30 subiecţi care folosesc apă potabilă din sursă controlată sanitar.

Criteriile de selecţie a lotului investigat: vârstă, sex, sursa de apă potabilă, antecedente personale (evoluţia sarcinii, greutate la naştere, afecţiuni cronice sugestive pentru intoxicaţii cronice). Alţi factori investigaţi: obiceiurile alimentare, ocupaţia, sedentarismul, stresul, nivelul de trai, apartenenţa religioasă diferenţiază subiecţii investigaţi în grupe de risc.

Investigaţiile de laborator au vizat aprecierea profilului metabolic general la cele două loturi studiate: hemoleucogramă – metoda Coulter, VSH – metoda Westerngreen, glucoză plasmatică şi urinară – metoda Trinder GOD-POD, uree plasmatică şi urinară - metoda urează-GLDH, creatinină plasmatică şi urinară - metoda Jaffé, transaminaze GPT – metoda IFCC - LDH-NADH şi GOT – metoda IFCC - MDH-NADH, colesterol – metoda CHOD-POD, trigliceride - metoda GPO-POD, proteine totale – metoda biuret, fosfataza alcalină – metoda p-nitrofenil-fosfat, ASLO – metoda latex-aglutinare, sumar urină şi sediment urinar.

REZULTATE

Analiza rezultatelor obţinute s-a făcut după următoarele criterii:

1. Structura lotului investigat.

Lotul investigat cuprinde 60 de subiecţi din mediu rural aflaţi în evidenţa medicului de familie: 48,33% subiecţi de sex masculin – SM - (15% până în 20 ani, 23,33% între 21 şi 45 ani şi 10% peste 45 ani, media de vârstă este de 27 ani ± 15,75 ani cu limitele de vârstă 6 şi 47 ani) şi 51,66% subiecţi de sex feminin – SF - (16,66% până în 20 ani, 22% subiecţi între 21 şi 45 ani şi 13% peste 45 ani, media de vârstă este de 25,93 ani ± 15,42 ani, cu limitele de vârstă 6 şi 48 ani (tab. 1, fig. 1).

M – sex masculin, F – sex feminin, ** IMC – indice masă corporală

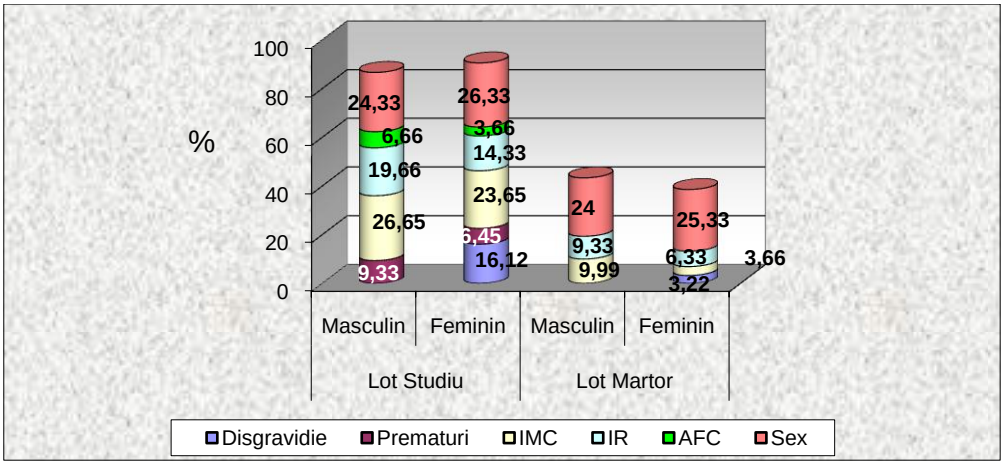

Fig. 1. Structura lotului investigat

(IMC – indice de masă corporală, IR – infecţii repetate, AFC – afecţiuni cronice).

În cadrul antecedentelor personale am constatat prezenţa disgravidiei la 16,12% subiecţi din lotul de studiu (LS) şi la 3,22% subiecţi din lotul martor (LM); prematuritatea la naştere este prezentă la 9,33% SM şi 6,45% SF din LS, iar greutatea normală la naştere au prezentat 79,66% SM şi 78,54% SF din LS şi 91,55% SM şi 93,66% SF din LM. Indicele de masă corporală (IMC) este afectat la 26,65% SM (scăzut la 16,66% până în 20 ani, 6,66% între 21 şi 44 ani şi crescut la 3,33% peste 45 ani) şi la 23,65% SF din LS (scăzut la 13,33% până în 20 ani, şi crescut la 6,66% între 21 şi 44 ani şi crescut la 3,66% peste 45 ani). IMC la subiecţii LM, este crescut la 9,99% SM (6,66% între 21 şi 44 ani şi 3, 33% peste 45 ani) şi la 3,66% SF între 21 şi 44 ani.

Infecţii repetate (amigdalite, otite, faringite, genito-urinare, stafilococii cutanate etc.) prezintă 19,66% SM şi 14,33% SF din LS comparativ cu 9,33% SM şi 6,33% SF din LM, iar afectări cronice hepatice şi renale (litiază renală, pielonefrită cronică) 6,66% SM şi 3,66% SF din LS.

2. Investigaţii de laborator.

Investigaţiile de laborator efectuate indică:

– Scăderea moderată a constantelor eritrocitare la 20,32% SM (12,33% până în 20 ani, 4,66% între 21 şi 44 ani şi 3,33% peste 45 ani) şi la 21,65% SF (10,66% până în 20 ani, 4,33% între 21 şi 44 ani şi 3,66% peste 45 ani) din LS.
– Nivelul glicemiei este crescut la 4,66% SM peste 45 ani şi la 3,66% SF (1,33% între 21 şi 44 ani şi 2,33% peste 45 ani) din LS şi la 1,33 SM din LM.
– Colesterolul seric este crescut la 10,99% SM (4,66% între 21 şi 44 ani şi 6,33% peste 45 ani) şi la 11,99% SF (4,33% între 21 şi 44 ani şi 7,66% peste 45 ani) din LS, iar din LM la 2,66% SM şi 2,33% SF peste 45 ani.
– Trigliceridele serice sunt crescute la 4,66% SM peste 45 ani şi la 6,33% SF peste 45 ani din LS şi la 2,33% SF peste 45 ani din LM.
– Testele de hepatocitoliză sunt pozitive la 8,32% SM (2,33% până în 20 ani, 1,66% între 21 şi 44 ani şi 4,33% peste 45 ani) şi la 7,65% SF (1,66% până în 20 ani, 2,33% între 21 şi 44 ani şi 3,66% peste 45 ani) din LS.
– ASLO este crescut la 16,99% SM (11,33% până în 20 ani, 5,66% între 21 şi 44 ani) şi la 15,99% SF (12,66% până în 20 ani, 3,66% între 21 şi 44 ani) din LS şi la 1,66% SM din LM (fig. 2).

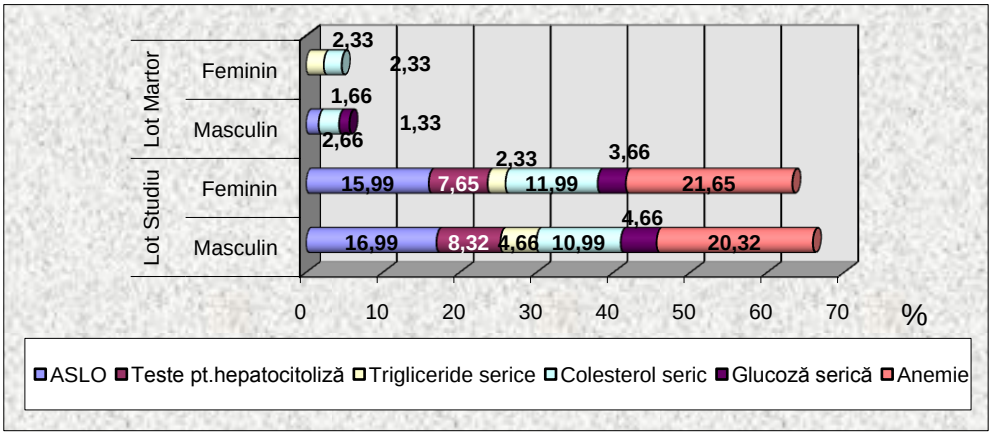

Fig. 2. Investigaţii de laborator sanguine

- Prezenţa nitriţilor în urină a fost identificată la 30,66% SM şi la 34,33% SF din LS.
- Uroculturi pozitive au prezentat 2,65% SM şi la 16,65% SF din LS.
- Cristalurie cu semnificaţie patologică a fost prezentă la 5,33% SM şi la 3,66% SF din LS (fig. 3).

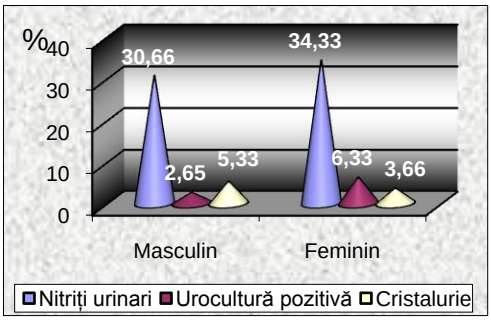

Fig. 3. Investigaţii de laborator în urină.

CONCLUZII

Apa, cu indicatorii fizici, chimici şi bacteriologici de evaluare în domeniul normal de potabilitate, atât sub aspect cantitativ cât şi sub aspect calitativ – al constituenţilor chimici conţinuţi – deţine un rol important în desfăşurarea normală a proceselor metabolice şi în consecinţă în menţinerea homeostaziei organismului.

Consumul îndelungat de apă cu constituenţii minerali prezenţi în exces, absenţi sau insuficienţi, poluarea biologică, chimică (reziduuri menajere, zootehnice, îngrăşăminte folosite în agricultură) directă a apei sau mai frecvent indirect prin intermediul solului, determină în timp dereglări metabolice complexe cu afectarea performanţelor morfo-funcţionale şi psihice ale individului. Receptivitatea la agenţii poluanţi externi este crescută la organismele tinere, în dezvoltare, iar consecinţa imediată şi ulterioară pentru organism este dezvoltarea psihosomatică deficitară, rezistenţă scăzută la factorii de mediu, consecinţe mutagene şi cancerigene.

Disgravidia, prematuritatea la naştere, afectarea IMC mai frecventă la subiecţii care au ca sursă de apă potabilă apa de fântână, comparativ cu subiecţii care folosesc apa din surse controlate sanitar, este o posibilă consecinţă a poluării apei de consum.

In cazul antecedentelor personale patologice se remarcă la subiecţii LS rezistenţă scăzută la agenţi infecţioşi datorită episoadelor infecţioase repetate pe care le prezintă şi a afectării cronice a ficatului şi a rinichilor – organe cu rol major în metabolizarea şi eliminarea noxelor din organism.

Rezultatele de laborator confirmă datele anamnestice constatate şi identifică aportul extern crescut de nitroderivaţi, cu probabilitatea ce mai mare prin apa ingerată.

Identificarea şi neutralizarea poluanţilor din sol şi apă, folosirea corectă a îngrăşămintelor agricole, îndepărtarea corespunzătoare a deşeurilor menajere, zootehnice şi nu în ultimul rând educaţia sanitară a colectivităţii sunt măsuri preventive de poluare a mediului extern, inclusiv a apei subterane şi de profilaxie pentru numeroase afecţiuni.

CONSTRUCTION AND CHARACTERIZATION OF A SELECTIVE MEMBRANE ELECTRODE FOR TENOXICAM DETERMINATION (Abstract): This paper describes the construction and characterization of a selective membrane electrode which can be used for determination of tenoxicam. **Material and method**: The electroactive compound is a precipitate obtained in 2 N hydrocloric acid solution containing tenoxicam in which a solution of iodine is added. The membrane is made by mixing the electroactive compound with polyethylene using tetrahydrofurane as solvent. The solution is evaporated in order to obtain a thick membrane, which is attached at one end of a PVC tube and is fixed with the same polymeric solution. In this tube an internal Ag/AgCl reference electrode is inserted. The assembly is filled with an internal solution containing tenoxicam. The electrode was characterized (electrode slope, selectivity, optimal pH range, response time, life time). The developed method was validated. **Results**: The method showed a good liniarity in the range of 10^{-6} – 10^{-1} M (the correlation coefficient r = 0.9999). The detection limit (LD) was 7.347 x 10^{-7} M and the quantification limit (LQ) was 1.017 x 10^{-6} M. There were established the precision (RSD = 1.79%) and the accuracy (mean recovery is 100.17%) **Conclusions**: The experimental results demonstrated a good sensibility. **Key words:** TENOXICAM, MEMBRANE-SELECTIVE ELECTRODE, POTENTIOMETRY, VALIDATION

Tenoxicamul face parte din clasa antiinflamatoarelor nesteroidiene (AINS) din generaţia a II-a, fiind indicat în terapia simptomatică a afecţiunilor reumatice inflamatorii dureroase şi degenerative, în artrita reumatoidă, osteoartrită, sciatică, lombalgie, gonartroze etc.

Lucrarea de faţă prezintă construcţia şi caracterizarea unui electrod membrană selectiv, precum şi metoda de determinare potenţiometrică a tenoxicamului ce foloseşte acest electrod.

MATERIAL ŞI METODĂ

Reactivi şi aparatură:

- soluţie stoc tenoxicam 10^{-1} M în acid clorhidric 0,1 N;
- soluţii de lucru tenoxicam (10^{-2} M–10^{-8} M) obţinute prin diluţie cu apă din soluţia stoc;
- soluţie internă de referinţă – soluţie de tenoxicam 10^{-5} M în soluţie saturată de AgCl; (această soluţie se obţine prin diluţia unei soluţii de tenoxicam 10^{-1} M cu soluţie saturată de AgCl);
- soluţii tampon, diferite valori ale pH-ului (1,2-10) preparate după Clark şi Lubs (1);
- soluţii apoase de KNO_3 0,01 M, 0,1 M, 1 M, 2 M;
- soluţii apoase 10^{-3} M de KNO_3, NaCl, 2-aminopiridină;
- electrod de construcţie proprie utilizând

complexul tenoxicam-triiodură;
- electrod de Ag/AgCl;
- potenţiometru pH/mV Hanna 301.

Sinteza complexului tenoxicam – triiodură. La 100 mL soluţie de tenoxicam se adaugă 50 mL soluţie acid clorhidric 2N, apoi sub agitare continuă şi în porţiuni mici, 50 mL soluţie triiodură de potasiu; se formează un compus greu solubil în apă, de culoare brun închis. Precipitatul obţinut se separă prin creuzet filtrant G_4, se spală cu o soluţie saturată a complexului tenoxicam – triiodură, după care se usucă până la masă constantă la temperatura camerei, în exicatorul de vid.

Prepararea membranei selective. 0,02 g compus tenoxicam-triodură se dizolvă în 10 mL soluţie de polietilenă 5% şi se adaugă 0,2 mL dibutilftalat cu rol de plastifiant. Din această soluţie se introduc 1,5 mL în interiorul unui inel din inox cu diametrul interior de 20 mm, aşezat pe o placă din sticlă şi lipit în exterior cu soluţie de polietilenă în tetrahidrofuran (fig. 1). Deasupra inelului se aşează o hârtie de filtru perforată pentru a proteja membrana de diverse impurităţi în timpul evaporării solventului, iar deasupra hârtiei de filtru se aşează un alt inel cu rol de greutate.

După evaporarea solventului, în interiorul inelului rămâne o membrană polimerică ce are înglobat materialul electroactiv (2).

Construcţia electrodului membrană selectiv. Pentru corpul electrodului s-a folosit o eprubetă din polietilenă. La capătul rotund al acesteia s-a realizat o perforaţie pe axul cilindrului (în care se introduce electrodul intern de referinţă) şi o perforaţie pe partea laterală care serveşte la umplerea electrodului construit cu soluţia internă de referinţă (o soluţie de tenoxicam 10^{-5} M realizată într-o soluţie saturată de clorură de argint).

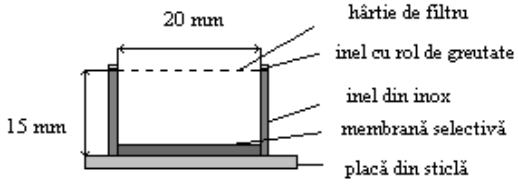

Fig. 1. Prepararea membranei selective

La celălalt capăt al eprubetei din polietilenă s-a fixat membrana preparată, aşa cum a fost descris, prin lipire cu ajutorul unui adeziv obţinut prin dizolvarea polietilenei în tetrahidrofuran, soluţie 5%.

Ca electrod intern de referinţă se utilizează un electrod de Ag/AgCl obţinut dintr-un fir de argint care se fixează într-un ansamblu din material plastic şi se conectează la un cablu ecranat. După realizarea conexiunii, firul de argint se curăţă la suprafaţă prin spălare cu o soluţie de acid azotic după care se imersează într-o soluţie diluată de acid clorhidric timp de 24 ore. Pe suprafaţa firului de argint se depune un strat subţire de AgCl (1).

Caracteristicile funcţionale ale electrozilor membrană selectivi. Celula electrochimică este formată din electrodul membrană ion – selectiv de construcţie proprie ca electrod indicator şi electrodul de Ag/AgCl cu rol de electrod de referinţă extern. Ambii electrozi sunt imersaţi în soluţia probei de analizat care conţine tenoxicam şi sunt conectaţi la un milivoltmetru electronic cu rezistenţă internă mare.

Au fost studiate:
- *funcţia electrodică:* s-au efectuat măsurători de potenţial pe o serie de soluţii de tenoxicam de concentraţie 10^{-8} – 10^{-1} M. S-a trasat curba de calibrare a electrodului reprezentând potenţialul în funcţie de valoarea pC = – log [tenoxicam]. Se determină domeniul de răspuns liniar, panta electrodului şi potenţialul standard condiţional al electrodului (3).
- *influenţa tăriei ionice*: se efectuează determinări pe seturi de soluţii de tenoxicam, folosind soluţii de KNO_3 de diferite concentraţii pentru a ajusta tăria ionică. Se compară valorile pantelor dreptelor de calibrare obţinute prin metoda regresiei liniare şi se lucrează în conti-

nuare la o tărie ionică constantă pentru care panta a avut cea mai mare valoare (3,4).

- *efectul pH-ului* : se determină prin măsurarea potenţialului la trei nivele de concentraţie 10^{-2}, 10^{-4}, 10^{-6} M tenoxicam. Modificarea pH-ului se realizează prin adăugare de soluţii tampon (1).
- *timpul de răspuns şi timpul de viaţă* : s-au înregistrat valorile potenţialelor în funcţie de timp.
- *selectivitatea electrozilor :* au fost testaţi din punctul de vedere al interferenţei ionilor K^+, NH_4^+, Cl^- şi NO_3^- deoarece aceştia sunt introduşi în soluţiile probelor de măsură în cazul ajustării pH-ului şi a tăriei ionice, dar şi al 2-aminopiridinei deoarece reprezintă principala impuritate care poate apărea în urma procesului de sinteză. Selectivitatea este apreciată prin coeficientul de selectivitate K (5).

Mod de lucru. Din soluţia stoc de tenoxicam 10^{-1}M se prepară prin diluţii succesive cu apă distilată soluţiile de lucru, de concentraţii în intervalul 10^{-2} – 10^{-6} M. Din fiecare soluţie de tenoxicam se măsoară un volum de 20 mL şi se aduc în pahare Berzelius. La soluţia de tenoxicam se adaugă un volum de 2,5 mL soluţie tampon pH = 1,2 şi 2,5 mL KNO_3 1 M. Se citesc valorile potenţialului folosind electrodul de construcţie proprie şi electrodul de referinţă de Ag/AgCl.

Validarea metodei

Determinarea liniarităţii : se prepară prin diluţii succesive cu apă distilată soluţiile de lucru de concentraţii cuprinse în intervalul 10^{-2} – 10^{-6} M. Se citesc valorile potenţialului folosind aceeaşi celulă electrochimică. Datele obţinute s-au prelucrat prin regresie matematică şi s-a trasat curba de calibrare. Metoda se consideră liniară dacă coeficientul de corelaţie este mai mare decât 0,998.

Precizia şi exactitatea : au fost analizate probe pentru următoarele concentraţii : 10^{-3} M, 10^{-4} M şi 10^{-5} M. În cazul preciziei se efectuează 2 seturi de probe pentru a evalua repetabilitatea metodei şi precizia intermediară. Pentru fiecare valoare a concentraţiei au fost efectuate trei determinări. Precizia şi exactitatea se exprimă prin deviaţia standard relativă (RSD) a valorilor obţinute care trebuie să fie mai mică de 2%.

Limita de detecţie şi cuantificare s-a calculat utilizând metoda grafică (6,7,8).

REZULTATE ŞI DISCUŢII

Funcţia electrodică. În fig. 2 este reprezentată grafic funcţia electrodică a electrodului tenoxicam selectiv.

Panta electrodului pentru domeniul liniar este P = –29,90 mV/decadă de concentraţie, iar potenţialul standard condiţional al electrodului determinat de pe curba prezentată în fig. 2 este E_0' = + 372,1 mV.

ţialului de electrod înregistrate la diferite valori ale tăriei ionice sunt prezentate în tab. I. Tăria ionică (constantă) pentru care panta a avut cea mai mare valoare se realizează prin adăugare de soluţie KNO_3 1 M.

Efectul pH-ului. Domeniul de pH optim este cuprins între 1,2 şi 2,0. Măsurătorile de potenţial pentru curba de calibrare şi determinarea potenţiometrică a tenoxicamului au fost efectuate după ajustarea pH-ului la valoarea 1,2 prin adăugare de soluţie tampon pH = 1,2.

Timpul de răspuns şi durata de întrebuinţare a electrodului. Timpul de răspuns este de aproximativ 15 secunde. Stabilitatea valorilor potenţialului de electrod este bună pentru o perioadă de aproximativ 2 luni, după care valoarea pantei electrodului începe să se modifice fapt ce indică degradarea membranei selective.

Selectivitatea electrodului. Valorile coeficienţilor de selectivitate sunt redate în tab. II.

Valorile coeficientului de selectivitate, K, sunt foarte mici deci, prezenţa ionilor

Date statistice	**Medie** = 100,76% **RSD**=1,85%		**Medie** = 100,73% **RSD**=1,73%		**Medie** = 100,17% **RSD**=1,93%	

testaţi în probe nu influenţează calitatea determinărilor.

Validarea metodei

Determinarea liniarităţii. S-a studiat liniaritatea pentru domeniul de concentraţie 10^{-8} - 10^{-1} M. Datele obţinute sunt evaluate statistic (tab. III), iar prelucrarea acestora conduce la obţinerea dreptei de calibrare (fig. 3).

Domeniul de concentraţii în care electrodul prezintă un răspuns liniar este cuprins între 10^{-6} M şi 10^{-1} M. Dreapta de calibrare calculată prin regresie matematică este :

$$E = -29{,}994 \times pC + 371{,}65;$$

$$r^2 = 0{,}9999$$

Limita de detecţie şi limita de cuantificare

Limita de detecţie are valoarea pC = 6,134 $(LD = 7{,}347 \times 10^{-7} M)$.

Limita de cuantificare are valoarea pC = 5,993 $(LC = 1{,}017 \times 10^{-6} M)$.

Precizia metodei. Se constată că atât pentru fiecare set de date separat, cât şi pentru ambele seturi de date luate împreună deviaţia standard relativă are o valoare mai mică de 2% (RSD = 1,79%), deci metoda de analiză este precisă (tab. IV).

Exactitatea. Din valorile experimentale (tab. IV) se constată că, pe domeniul de concentraţie studiat, regăsirea medie este de 100,17% (minim 97,20 % şi maxim 103,36 %), iar deviatia relativă standard (RSD= 1,93) este mai mică de 2% deci metoda de analiză propusă este exactă.

CONCLUZII

A fost construit şi caracterizat un electrod

membrană selectiv ce utilizează ca material electroactiv complexul tenoxicam-triiodură.

Electrodul membrană a fost caracterizat stabilindu-se funcţia electrodică, efectul pH-ului, influenţa tăriei ionice, timpul de răspuns şi timpul de întrebuinţare, precum şi selectivitatea electrodului.

Electrodul membrană selectiv a fost utilizat pentru determinarea potenţiometrică directă a tenoxicamului din soluţii apoase.

Metoda de analiză a fost validată, stabilindu-se: liniaritatea metodei (pe domeniul 10^{-1} M - 10^{-6} M), coeficientul de corelaţie (r = 0,9999), limita de detecţie (7,34 x 10^{-7} M), limita de cuantificare (1,01 x 10^{-6} M), precizia metodei (RSD = 1,79%) şi exactitatea metodei (regăsire medie = 100,17%).

În concluzie, metoda de analiză propusă este simplă, uşor de executat şi sensibilă. De asemenea, metoda este liniară, precisă şi exactă.

NOUTĂŢI

FUMATUL CRONIC ALTEREAZĂ COMPOZIŢIA ŞI PROPRIETĂŢILE LIPIDELOR MEMBRANARE ERITROCITARE

Fumatul este un obicei major în viaţa cotidiană a multor oameni. Studiind modificările induse de fumat în compoziţia lipidică a membranei eritrocitare, fluiditatea membranară şi rolul oxidului nitric (NO), pe un lot de 30 de fumători (12 +/- 2 tigarete /zi, vârsta 35 +/- 8 ani), comparativ cu un lot de 30 de nefumători, s-au observat, în cazul fumătorilor, următoarele modificări: nivel plasmatic crescut de nitriţi/nitraţi, nivel ridicat al hemolizei, o creştere a gradului de peroxidare a lipidelor şi a raportului colesterol/proteine (C/P), precum şi o scădere a activităţii Na^+/K^+-ATPazei şi a grupărilor sulfhidril. Nivelul de NO, în cazul celulelor lizate, a fost corelat pozitiv cu raportul C/P (r = 0,56) şi cu valoarea anizotropiei de fluorescenţă. În concluzie, fumatul induce generarea de specii reactive oxigen/nitrogen care pot altera proprietăţile fizico-chimice ale membranei eritrocitare, cu implicaţii majore fiziopatologice (Padmavathi P, Reddy VD, Kavitha G, Paramahamsa M, Varadacharyulu N. AN ALTERNATIVE METHOD FOR THE REMOVAL OF THE OCULAR ARTIFACT FROM THE EEG SIGNAL (Abstract): The aim of this paper is to develop a technique of rejection or minimization of ocular artifacts from the electroencephalographic (EEG) recordings. **Material and method**: The method presented is based on mathematical morphology. The algorithm and the individual structuring element are presented along with the particularities concerning the parameters that characterize the structuring element. **Results**: The obtained results are shown in a comprehensive form by means of an illustrating example that evidences the efficiency of the method. **Conclusions**: The proposed method simplyfies the task of removing the ocular artifacts by means of nonlinear filtering and introduces a new structural element for the job. The results are validated by means of Fourier analysis and this clearly shows its effectiveness. **Key words**: BRAIN-COMPUTER-INTERFACE, EEG ARTIFACT, MATHEMATICAL MORPHOLOGY, STRUCTURING ELEMENT

When dealing with brain-computer interfaces (BCI), the electro-encephalographic (EEG) signal is the one that facilitates the communication between the human being and the machine. Some features of the EEG signal that were previously chosen to represent the information carrier are usually processed in order to detect the subject's response to a stimulus which was typically computer generated. To do so, only the real EEG signal must be considered; it is a well known fact that eye movement, heartbeats and muscle artifacts are unwanted signals that interfere with the actual EEG signal. Due to the various artifacts that are present in BCI systems, not all of them can be rejected. Most authors do not show if they took into account the artifacts in their analysis (1). The goal of an artifact-removal method is to put into practice the possibility of removing the artifacts, while keeping the EEG signal intact. The main methods for the reduction of artifacts from the EEG signals are: linear filtering (2), regression (3), principal component analysis (PCA) (4), independent component analysis (ICA) (5), nonlinear adaptive filtering (6) and wavelet transform (7). Any new method may be a good candidate to replace the existing ones if it is easy to implement, the artifact rejection is satisfactory and, at least, as effective as the actual methods.

We intend to show the way in which mathematical morphology may be an answer to the EEG artifact removal. The shape description based on mathematical morphology was used, from its introduction by Matheron and Serrat (8,9,10), in image analysis or in biological research like the one in (11). Works of Maragos and Schafer (12,13)

allowed additional fields of interest like nonlinear filtering of signals. Our application is based on the last application and, as far as we know, wasn't applied for artifact removal from the EEG signal until now.

MATERIALS AND METHOD

We have used the EEG datasets from the SIESTA project (14). Several types of artifacts such as ocular, cardiac and muscle artifacts were recorded along with the sleep EEG. Seven EEG channels of 90 minutes each, from 15 subjects were available. For our purpose, we have chosen an EEG segment contaminated with ocular artifacts. Besides the EEG recordings there were also recorded vertical (VEOG) and horizontal EOG (HEOG) signals. The sampling rate of the signal was 256 Hz.

By means of a simple visual inspection, it was found that the effect of ocular artifacts (slow eye movements) is dominant in the frontal channels FP1 and FP2 recordings (slow wave EEG artifacts).

Mathematical morphology deals in our case with two time functions: the first one is the EEG recording itself and the second is the structuring element. Based on the shape of the structuring element and of two basic operators which will be defined below, it is possible to "extract" the artifacts. Usually, the structuring element is a circle when dealing with images. For signal processing purposes, more complicated shapes are needed, because there are several parameters that must be "adapted" to the signal to perform a high-quality artifact removal. The circle has just one parameter, the radius, but nevertheless, this may be cured transforming it into an ellipse which has two parameters, the lengths of its axes; unfortunately this doesn't guarantee the success of the operation.

Our work showed that for the structuring element the best suited function is a second degree one, given by the following formula:

$$se(t) = -\alpha t^2 + \beta \qquad \textbf{(1)}$$

Parameters á and â are in fact the values of two statistical indicators, the standard deviation and the mean value:

$$\alpha = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(v_i - \beta)^2}, \quad \beta = \frac{1}{N}\sum_{i=1}^{N} v_i \qquad \textbf{(2)}$$

where v_i are the samples of the EEG signal.

The two basic operators used by the mathematical morphology are *erosion* and *dilation*. For a comprehensive cover of this topic, reference (15) may be a good choice. Shortly, *erosion* performs a search for a minimum between the values of the function and those of the structuring element in a given interval, while *dilation* does the same for the maximum. This is done for each argument of the function representing the signal.

Based on these two operators, one may define mixtures between them, bearing in mind the fact that the order in which they are applied is essential. In this way, other two functions are defined, *closing* and *opening*, based on the initial signal, *v* and the structuring element, *se*:

$$closing(v, se) = erosion(dilation(v, se)) \qquad \textbf{(3)}$$

$$opening(v, se) = dilation(erosion(v, se)) \qquad \textbf{(4)}$$

There is also the possibility of applying *closing* and *opening* operators one after the other to get the desired result. In our study, to remove the ocular artifacts we used the mean value obtained from the *close-opening* and *open-closing* functions:

$$close_opening(v, se) = \\ = closing(opening(v, se)) \qquad \textbf{(5)}$$

$$open_closing(v, se) = \\ = opening(closing(v, se)) \qquad \textbf{(6)}$$

We used a small structure element, about 0.1% from the whole length of the EEG recording whose function is given by formula (1); it proved to be the best suited for the job.

RESULTS

As acknowledged above, the FP1 and FP2 EEG recordings were contaminated with ocular artifacts. The recording of the FP1 channel presents an artifact between samples 900 and 1100 (a slow eye movement resulting in slow-wave EEG artifact). Our purpose is to eliminate it using nonlinear filtering tools based on mathematical morphology.

First we applied the two basic operators, *erosion* and *dilation*; the result is presented in fig. 1 and fig. 2.

Next, *closing* and *opening* operators were applied and finally, the *close-opening* and *open-closing* operations were performed (figs. 3 and 4).

Finally, the artifact-free signal is presented in fig. 5. It was obtained by substracting the mean value of signals given by formulas (5) and (6) from the initial EEG recording.

In order to be able to compare the signals represented in fig. 5, we have represented their amplitude spectra (fig. 6 and fig. 7).

From the two figures above, it is worth noticing that the low frequency components (up to 7 Hz) are substantially reduced, while the high frequency components are preserved. So, this is a certain proof that the

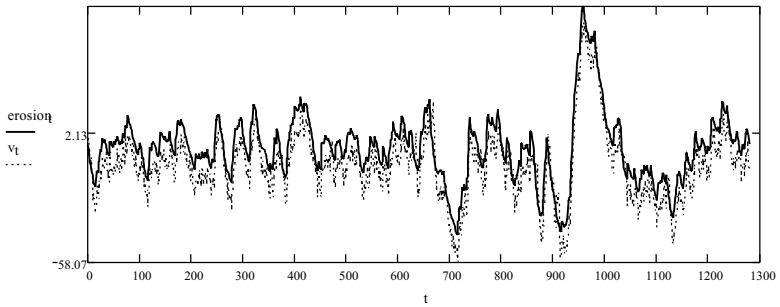

Fig. 1. Erosion (continuous line) vs. initial EEG signal (dotted line)

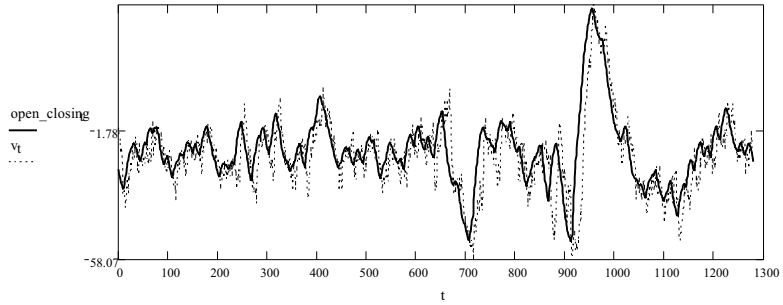

Fig. 4. Open-closing (continuous line) vs. initial EEG signal (dotted line)

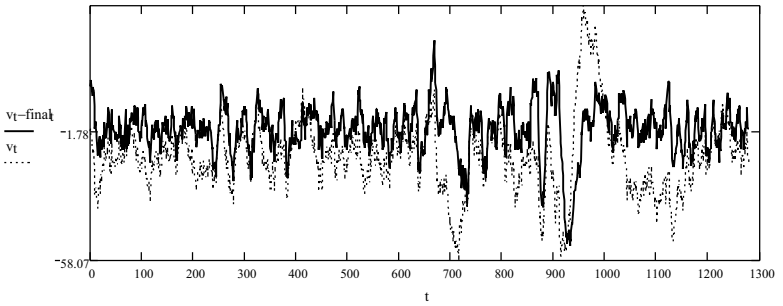

Fig. 5. Artifact-free signal (continous line) vs. initial EEG signal (dotted line)

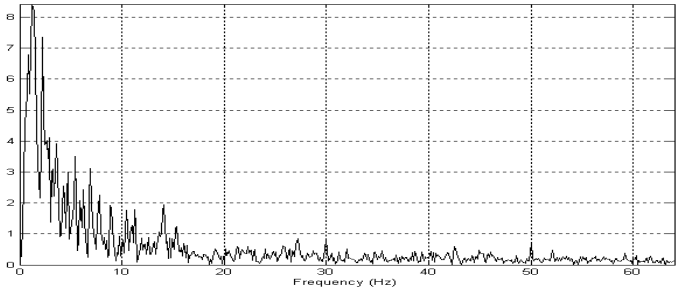

Fig. 6. Single-sided amplitude spectrum of the initial EEG signal

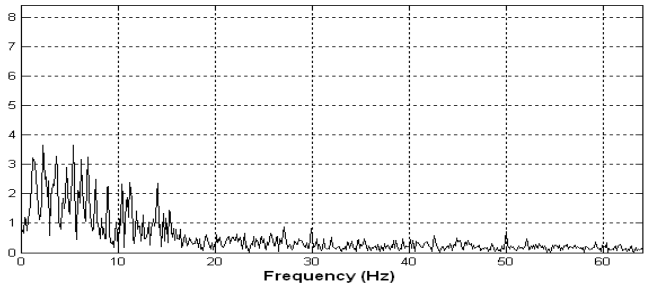

Fig. 7. Single-sided amplitude spectrum of artifact-free EEG

applied algorithm removed only the ocular artifacts (which are low frequency) without modifying the EEG signal. Similar results were obtained for the FP2 channel.

DISCUSSION

The use of mathematical morphology for artifact removal from the EEG signal may

be an efficient method involved in brain--computer interfaces. The method was priorly used for epileptic spikes detection, (16), in a somewhat different manner : the link between the signal and the parameters of the structuring element was optimised by means of dedicated software and the morphological operators involved different structure elements for *closing* and *opening*.

CONCLUSION

The method proposed in this paper is suitable for eye movement artifact removal from the EEG signal. Its simplicity lies in using the same structuring element for both *opening* and *closing* and in determining the parameters of the structuring element by means of the well known statistical indicators : the mean value and the standard deviation of the EEG signal.

SELECTIVE SEPARATION OF VITAMIN C AND 2-KETOGLUCONIC ACID BY FACILITATED PERTRACTION (Abstract) : The removal of vitamin C from a mixture with 2-ketogluconic acid by using a bulk liquid membrane (BLM) has been investigated. The studies on facilitated pertraction of vitamin C with Amberlite LA-2 indicated the major parameters that affect the separation efficiency : pH gradient between the two aqueous phases, carrier concentration in the liquid membrane and phase mixing intensity. The overall results obtained in this work showed that liquid membrane system can effectively be used to selectively separate vitamin C from its mixture with the fermentation by-product, 2-ketogluconic acid. **Key words :** VITAMIN C, 2-KETOGLUCONIC ACID, AMBERLITE LA-2, CARRIER, PERTRACTION

Vitamina C (acid ascorbic) este un nutrient esenţial vieţii şi poate fi sintetizată de către majoritatea speciilor animale şi vegetale, excepţie făcând primatele şi cobaiul. Este o vitamină hidrosolubilă implicată în metabolismul glucozei, al colagenului, al acidului folic şi al anumitor acizi aminaţi, în neutralizarea radicalilor liberi şi a nitrozaminelor, în reacţii imunologice care facilitează absorbţia fierului de către tubul digestiv, constituind un cofactor pentru o serie de enzime. În organismul uman, vitamina C deţine un rol deosebit de important, datorită caracterului său antioxidant, proprietate care justifică şi numeroasele utilizări în medicină şi alimentaţie (1,2). În cosmetică, vitamina C constituie un ingredient valoros al multor loţiuni şi creme, datorită acţiunii sale antioxidante şi protectoare a pielii împotriva radiaţiilor UV (3,4).

Acidul 2-cetogluconic este principalul produs secundar rezultat la obţinerea vitaminei C prin biosinteză, dar poate fi obţinut şi individual prin fermentaţie pornind de la sorboză, având utilizări în industria de sinteză (obţinerea xilitolului, fie prin decarboxilare, fie prin reducere chimică sau enzimatică) (3).

Vitamina C poate fi obţinută la nivel industrial prin două procedee, şi anume biosinteza cuplată cu transformarea chimică (procedeul Reichstein) şi fermentaţia în două stadii cu ajutorul unor microorganisme modificate genetic (1,2,5,6). Indiferent de procedeul utilizat, un intermediar inevitabil în sinteza sau biosinteza vitaminei C îl reprezintă acidul 2-cetogluconic. Diferenţele structurale între aceşti doi compuşi sunt datorate doar structurii lactonice (fig. 1), astfel încât caracteristicile fizico-chimice ale acizilor sunt destul de asemănătoare.

Ambii compuşi au caracteristici similare în ceea ce priveşte solubilitatea : sunt puternic solubili în solvenţi polari, în special apă, şi slab solubili în solvenţi organici

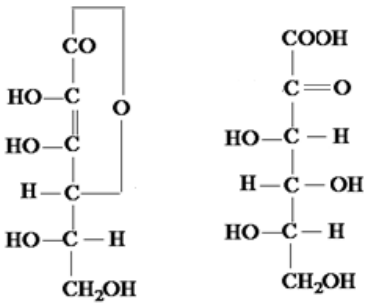

Fig. 1. Structurile chimice ale vitaminei C şi acidului 2-cetogluconic

(2). În consecinţă, separarea prin extracţie lichid-lichid din amestecul rezultat la fermentaţie este dificilă din punct de vedere economic. Bazându-se pe rezultatele anterioare privind mecanismul separării şi influenţa factorilor determinanţi în extracţia reactivă a vitaminei C şi a acidului 2-cetogluconic, studiile experimentale prezentate în continuare urmăresc stabilirea condiţiilor optime pentru separarea selectivă a celor doi componenţi prin pertracţie facilitată cu Amberlite LA-2 (9,10).

MATERIAL ŞI METODĂ

Instalaţia de pertracţie originală utilizată în vederea realizării experimentelor a fost prezentată în detaliu în lucrările anterioare (7,8). Aceasta utilizează o membrană lichidă liberă (cele două faze apoase miscibile sunt separate de stratul de solvent organic nemiscibil cu acestea care, însă, permite transportul masic al celor doi componenţi). Experimentele au fost realizate în sistem pseudostaţionar, soluţiile apoase fiind alimentate separat cu un debit volumic de 1,9 L/h.

Solventul organic care a constituit membrana lichidă a fost diclormetanul în care a fost dizolvat agentul purtător Amberlite LA-2 în concentraţii cuprinse între 0 şi 100 g/L). Faza apoasă iniţială a constat dintr-un amestec de 1 g/L acid 2-cetogluconic şi 7 g/L vitamina C, iar faza apoasă finală a constat din soluţii de hidroxid de sodiu, cu diferite valori ale pH-ului. Modificarea pH-ului celor două faze apoase la valorile prestabilite de programul experimental (intervalul 1 - 6 pentru soluţia iniţială şi 7 - 12 pentru cea finală) s-a efectuat cu soluţii 5% H_2SO_4, respectiv 5% NaOH, utilizând un pH-metru digitalic de tip HI 213 (Hanna Instruments).

Pentru a urmări desfăşurarea procesului s-au urmărit fluxurile masice iniţiale, n_i, şi finale, n_f, ale acizilor , factorul de permeabilitate prin membrana lichidă, P şi factorul de selectivitate (S) (7,8). Fluxurile masice s-au calculat prin dozarea concentraţiei ambilor compuşi din soluţia iniţială şi din rafinat şi efectuarea bilanţului de masă în sistemul de pertracţie. Factorul de permeabilitate prin membrana lichidă, P, este definit ca raportul între fluxul masic final şi iniţial al celor doi compuşi, iar factorul de selectivitate ca raportul între factorii de permeabilitate. Dozarea s-a realizat prin metoda HPLC, utilizând o coloană de tip Hamilton PRP-X300 (diametru 4,1 mm, lungime 150 mm), la temperatura de 25°C. Eluentul folosit a fost o soluţie apoasă 4 mM de acid sulfuric, cu un debit de 0,5 mL/min. Detecţia s-a realizat în domeniul UV la 210 nm.

REZULTATE ŞI DISCUŢII

În scopul optimizării condiţiilor de operare pentru separarea selectivă a vitaminei C, s-au analizat efectul gradientului de pH dintre fazele apoase, al concentraţiei agentului purtător dizolvat în membrana lichidă şi intensitatea amestecării fazelor, principalii parametri care controlează procesul.

În studiul influenţei pH-ului fazelor apoase, trebuie ţinut cont de faptul că atât procesul de extracţie al celor doi compuşi, cât şi cel de reextracţie se bazează pe dependenţa coeficientului de distribuţie de pH-ul soluţiilor iniţială şi finală. Separarea vitaminei C şi viteza transferului de masă al ambilor compuşi din amestec sunt controlate de gradientul de pH dintre aceste

soluţii. Astfel, s-au observat diferenţe majore între variaţia fluxurilor masice în funcţie de pH între cei doi compuşi (fig. 2). Odată cu creşterea pH-ului soluţiei din care se realizează extracţia, pH_i, are loc scăderea continuă a fluxurilor pentru vitamina C, în timp ce pentru acidul 2-cetogluconic graficul înregistrează un maxim corespunzător valorii de pH = 3.

În cazul vitaminei C, reducerea pH-ului soluţiei apoase iniţiale determină intensificarea fluxului masic dinspre soluţia apoasă iniţială spre membrana lichidă, datorită mecanismului de realizare a extracţiei reactive. Vitamina C reacţionează cu Amberlite LA-2, dizolvat în membrana lichidă, la interfaţa de separare dintre faza apoasă iniţială şi membrană formând complexul solut-agent purtător puternic hidrofob. Creşterea pH-ul fazei apoase iniţiale controlează transformarea vitaminei C în acid dehidroascorbic, incapabil să reacţioneze cu Amberlite LA-2 (determinând scăderea fluxului masic iniţial) (1). Datorită capacităţii acidului 2-cetogluconic de a forma dimeri la pH puternic acid, acesta este extras cu eficienţă ridicată doar la un pH al fazei apoase mai mare decât 2 (10). În acelaşi timp, depaşirea valorii de pH corespunzătoare pK_a-ului acidului (pK_a = 2,66 la 25°C (2)) determină disocierea grupării –COOH, împiedicând reacţia cu agentul purtător la interfaţa dintre faza apoasă iniţială şi membrana lichidă (9). Fluxurile masice superioare ale acidului 2-cetogluconic în domeniul de pH = 3-5 se datorează acidităţii superioare a acestuia comparativ cu vitamina C, caracterul acid fiind cel care controlează viteza reacţiilor interfaciale dintre solut şi agentul purtător. Din acelaşi motiv, reducerea fluxului masic iniţial este mai accentuată pentru acest acid odată cu apropierea de domeniul neutru de pH (fig. 2).

Scăderea pH-ului fazei apoase iniţiale induce creşterea concentraţiei vitaminei C în membrana lichidă, determinând creşterea

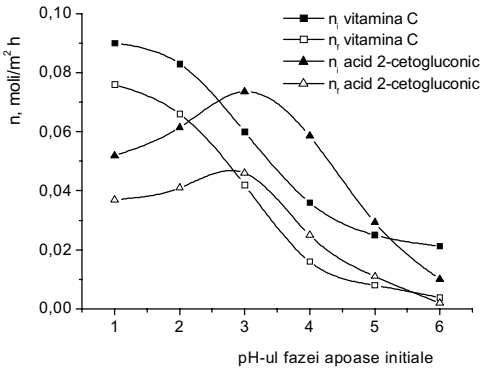

Fig. 2. Influenţa pH-ului fazei apoase iniţiale asupra fluxurilor masice ale vitaminei C şi acidului 2-cetogluconic (pH_f = 11, concentraţia Amberlite LA-2 = 40 g/L, turaţia = 500 rpm)

fluxului masic final, deoarece fluxurilor masice finale ale celor doi compuşi sunt direct dependente de concentraţia acestora în membrana lichidă. În cazul acidului 2-cetogluconic, fluxul masic dinspre membrana lichidă înspre faza apoasă finală are o alură similară celui iniţial. Acesta creşte până la o valoare a pH_i-ului de 3, apoi se reduce, datorită unei eficienţe scăzute a extracţiei reactive, care induce o concentraţie mai mică a acidului şi în membrana lichidă.

Influenţa pH-ului fazei apoase finale asupra fluxurilor masice iniţiale şi finale ale celor doi compuşi este reprezentată în figura 3. Se observă intensificarea acestora atât pentru vitamina C, cât şi pentru acidul 2-cetogluconic, datorită creşterii vitezei de transformare în sarea de sodiu, şi, respectiv, a vitezei de reextracţie determinată de mărirea concentraţiei agentului de reextracţie (hidroxid de sodiu) şi, implicit, a gradientului de pH dintre cele două faze apoase (fig. 3).

Factorii de permeabilitate pentru ambii componenţi ai amestecului scad cu creşterea pH-ului fazei apoase iniţiale, după cum se poate observa din figura 4. Limitările induse de difuzia dinspre membrana lichidă către faza apoasă finală, mai accentuate în cazul vitaminei C datorită structurii ciclice

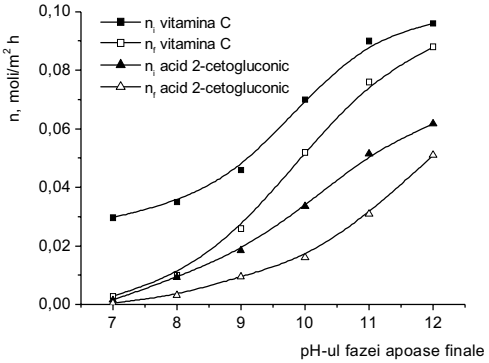

Fig. 3. Influenţa pH-ului fazei apoase finale asupra fluxurilor masice ale vitaminei C şi acidului 2-cetogluconic (pH_i = 1, concentraţia Amberlite LA-2 = 40 g/L, turaţia = 500 rpm)

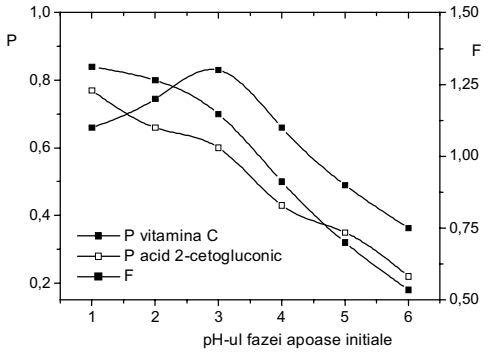

Fig. 4. Influenţa pH-ului fazei apoase iniţiale asupra factorilor de permeabilitate a vitaminei C şi acidului 2-cetogluconic şi a factorului de selectivitate (pH_f = 11, concentraţia Amberlite LA-2 = 40 g/L, turaţia = 500 rpm)

mai voluminoase, cumulat cu faptul că fluxul masic iniţial al acidului 2-cetogluconic este mult mai mic pentru $pH_i > 5$, explică valorile superioare ale factorului de permeabilitate al acidului comparativ cu cele corespunzătoare vitaminei C pentru pH > 4 al fazei apoase iniţiale.

Factorul de selectivitate, F, calculat ca raportul între factorii de permeabilitate a vitaminei C şi acidului 2-cetogluconic, înregistrează o valoare maximă la pH = 3 pentru faza apoasă iniţială, care poate fi justificată prin diferenţa mare între concentraţiile din membrana lichidă a celor doi compuşi, la această valoare a pH-ului. Pentru acidul 2-cetogluconic, viteza de extracţie este superioară celei înregistrate pentru vitamina C, astfel încât cantitatea de acid extrasă în stratul de solvent este mult mai ridicată decât cea reextrasă, fluxul masic final neputându-l compensa semnificativ pe cel iniţial (fig. 4).

Creşterea valorii pH-ului fazei apoase finale induce mărirea factorilor de permeabilitate, ceea ce evidenţiază faptul că pe măsura apropierii de domeniul puternic acid, viteza de reextracţie a celor doi compuşi devine mai importantă decât viteza extracţiei reactive. Creşterea este mai accentuată pentru vitamina C, ca rezultat al vitezei superioare de extracţie la pH_i = 1 comparativ cu acidul 2-cetogluconic. Odată cu creşterea pH-ului acestei faze apoase, viteza de reextracţie creşte semnificativ, pentru pH_f = 12 fluxurile masice iniţiale fiind echilibrate de cele finale (P = 0,96), aproape întreaga cantitate de vitamină fiind reextrasă din membrană.

Factorul de selectivitate creşte cu creşterea pH-ului fazei apoase finale, observându-se atingerea unor valori maxime ale factorului de selectivitate pentru diferenţe minime de pH dintre soluţiile apoase (fig. 5).

Un alt parametru care influenţează eficienţa transportului prin membrane lichide îl reprezintă intensitatea amestecării celor două faze apoase. Mărirea turaţiei agitatoarelor care realizează amestecarea acestora s-a realizat până la 600 rpm, rotaţie care a permis menţinerea plană a interfeţei de contact dintre cele trei soluţii. Şi în cazul pertracţiei, creşterea continuă a fluxurilor masice cu turaţia corespunde unui proces limitat de difuzia componenţilor sistemului, în timp ce atingerea unui nivel constant de variaţie al fluxurilor indică trecerea în domeniul cinetic de desfăşurare a separării.

Din figura 6 se poate observa că intensificarea amestecării induce creşterea fluxurilor masice iniţiale şi finale atât pentru

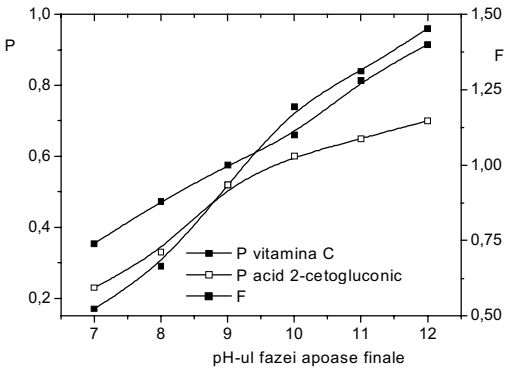

Fig. 5. Influenţa pH-ului fazei apoase finale asupra factorilor de permeabilitate a vitaminei C şi acidului 2-cetogluconic şi a factorului de selectivitate (pH_i = 1, concentraţia Amberlite LA-2 = 40 g/L, turaţia = 500 rpm)

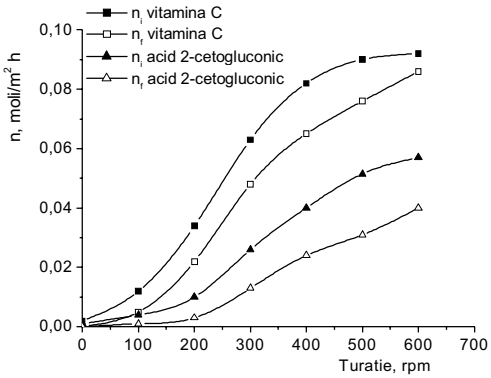

Fig. 6. Influenţa intensităţii amestecării fazelor apoase asupra fluxurilor masice ale vitaminei C şi acidului 2-cetogluconic (pH_i = 1, pH_f = 11, concentraţia Amberlite LA-2 = 40 g/L)

acidul 2-cetogluconic, cât şi pentru vitamina C, ca efect al reducerii rezistenţei datorate difuziei prin filmele de lichid din vecinătatea celor două interfeţe de separare. Fluxurile masice sunt mai mici pentru acidul 2-cetogluconic, evidenţiind un efect mai important al amestecării în cazul vitaminei C, datorită rezistenţei mai mari la difuzia prin straturile limită (fig. 6).

Fluxul masic final al acidului este mult mai mic comparativ cu cel iniţial, datorită stabilităţii superioare a complexului (acid 2-cetogluconic - Amberlite LA-2) în reacţia de reextracţie, respectiv formarea 2-cetogluconatului de sodiu.

Creşterea factorilor de permeabilitate cu turaţia, reprezentată în figura 7, sugerează faptul că difuzia ascorbatului de sodiu, respectiv a 2-cetogluconatului de sodiu, în faza apoasă finală creează o rezistenţă superioară celei opuse de difuzia din faza apoasă iniţială, datorită structurii chimice mai voluminoase a sărurilor. Factorul de selectivitate scade cu creşterea turaţiei, înregistrând un maxim atunci când fazele apoase sunt în repaus, caz în care, datorită diferenţelor între gradele de extracţie reactivă, fluxurile masice ale vitaminei C sunt mai mari decât cele ale acidului 2-cetogluconic (fig. 7).

Concentraţia agentului purtător, Amberlite LA-2, manifestă, de asemenea, o influenţă semnificativă asupra pertracţiei selective a vitaminei C, influenţând atât capacitatea de transport a membranei (difuzia complexului prin membrană), cât şi cinetica reacţiilor interfaciale. Conform rezultatelor experimentale reprezentate grafic în figura 8, se constată intensificarea fluxurilor masice iniţiale şi finale ale soluţiilor odată cu mărirea concentraţiei agentului purtător în membrana lichidă (fig. 8).

Această evoluţie a fluxurilor masice este

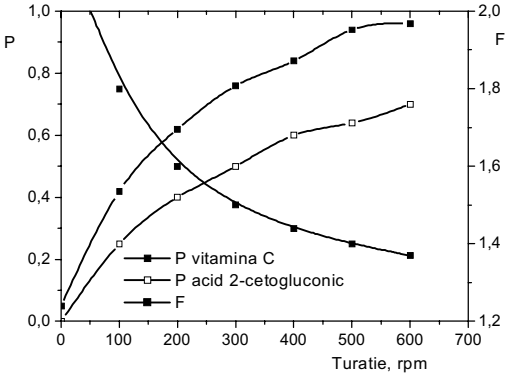

Fig. 7. Influenţa intensităţii amestecării fazelor apoase asupra factorilor de permeabilitate ale vitaminei C şi acidului 2-cetogluconic şi a factorului de selectivitate (pH_i = 1, pH_f = 11, concentraţia Amberlite LA-2 = 40 g/L)

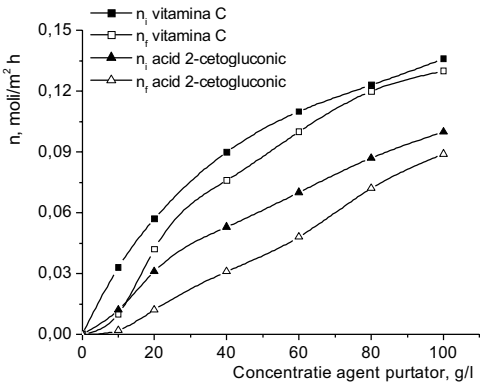

Fig. 8. Influenţa concentraţiei agentului purtător asupra fluxurilor masice ale vitaminei C şi acidului 2-cetogluconic (pH_i = 1, pH_f = 11, turaţia = 500 rpm)

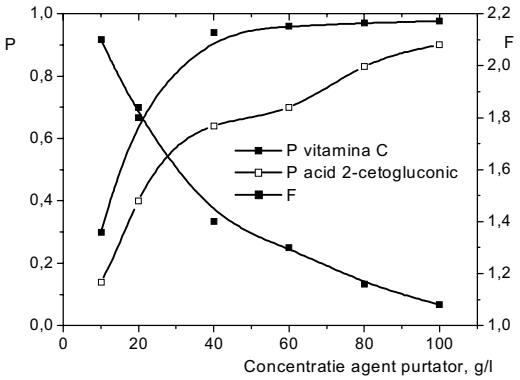

Fig. 9. Influenţa concentraţiei agentului purtător asupra factorilor de permeabilitate a vitaminei C şi acidului 2-cetogluconic şi a factorului de selectivitate (pH_i = 1, pH_f = 11, turaţia = 500 rpm)

consecinţa creşterii concentraţiei unuia dintre participanţii la reacţia chimică care se desfaşoară la interfaţa de separare dintre faza apoasă iniţială şi solvent. Creşterea concentraţiei Amberlite LA-2 în membrana lichidă manifestă un efect pozitiv mai accentuat asupra fluxurilor masice ale vitaminei C, datorită solvatării complexului format de către moleculele de extractant.

Aceeaşi evoluţie crescătoare o înregistrează şi factorii de permeabilitate, fapt evidenţiat de rezultatele expuse în figura 9, datorită rezistenţei de natură cinetică superioară care afectează procesul global de separare. În cazul vitaminei C, factorul de permeabilitate creşte până la o concentraţie de Amberlite LA-2 de 40 g/L, peste această valoare efectul acestui parametru devenind neglijabil.

Aplatizarea curbei este rezultatul unor eficienţe apropiate între procesele de extracţie şi reextracţie la cele două interfeţe ale membranei lichide. Deoarece la pH_i = 1, acidul 2-cetogluconic se găseşte sub formă de dimeri, factorul de permeabilitate este inferior celui corespunzător vitaminei C (fig. 9).

Factorul de selectivitate scade puternic cu creşterea concentraţiei agentului purtător, valoarea maximă (F = 2,1) fiind atinsă pentru concentraţia aminei de 10 g/L. La această valoare a concentraţiei, Amberlite LA-2 reacţionează preferenţial cu vitamina C, însă cu creşterea concentraţiei agentului purtător creşte probabilitatea reacţiei şi cu acidul 2-cetogluconic.

CONCLUZII

Rezultatele obţinute au demonstrat faptul că vitamina C poate fi extrasă selectiv din amestecul cu acidul 2-cetogluconic, produs secundar rezultat din procesul de fermentaţie. Parametrul cu importanţa decisivă asupra eficienţei pertracţiei a fost pH-ul soluţiei apoase. Astfel, pentru a separa selectiv vitamina C este necesară menţinerea pH-ului fazei apoase iniţiale la valoarea 1, corespunzătoare unor fluxuri masice superioare datorate mecanismului de realizare a extracţiei reactive. Agitarea fazelor iniţială şi finală are un efect pozitiv, însă nu similar, asupra vitezelor de extracţie şi, respectiv, de reextracţie, sugerând faptul că, în timp ce procesul de extracţie este controlat atât difuzional, cât şi cinetic, cel de reextracţie este controlat predominant de difuzie.

Experimentele au fost realizate în cadrul grantului ID 317/2007, finanţat de UEFISCSU - CNCSIS

NOUTĂŢI

EFECTELE ANTIDEPRESIVE ALE UNEI FRACŢIUNI POLIZAHARIDICE ACIDE DIN GINSENG

Rădăcinile speciei *Panax ginseng* C. A. Meyer (*Araliaceae*) sunt utilizate pentru proprietăţile tonic generale. Profilul farmacologic al extractelor de Ginseng este foarte complex ; extractele de Ginseng modulează axa hipotalamo-pituitaro-adrenergică şi activitatea sistemelor monoaminice. În contextul noilor teorii referitoare la etiopatogenia depresiei, extractele de Ginseng acţionează neuroprotector şi, în acelaşi timp, cresc rezistenţa celulelor la diferiţi agenţi agresori. Ginseng-ul conţine peste 15% polizaharide, neutre şi acide, solubile în apă, considerate a fi răspunzătoare pentru multe dintre efectele benefice ale extractelor. Fracţiunea polizaharidică neutră conţine, în principal, glucani şi cantităţi mici de arabinogalactani. Fracţiunea polizaharidică acidă este un amestec complex de pectine bogate în unităţi de tip arabinogalactan, ramnogalacturonan şi homogalacturonan. Această fracţiune a fost administrată animalelor de experienţă (şoareci masculi ICR) pe cale orală, în doze de 100 mg/kg şi 200 mg/kg. Administrarea s-a făcut zilnic, timp de o săptămână înainte de efectuarea experimentelor şi în timpul desfăşurării experimentelor. Au fost evaluate spontaneitatea şi abilităţile de socializare ale animalelor de experienţă, precum şi comportamentul acestora în testul labirintului şi testul înotului forţat. Fracţiunea polizaharidică acidă nu a influenţat spontaneitatea animalelor şi comportamentul acestora în testul labirintului. În doză de 100 mg/kg, fracţiunea polizaharidică acidă a redus semnificativ imobilitatea animalelor în testul înotului forţat ; în doze de 100 mg/kg şi 200 mg/kg, această fracţiune a diminuat agresivitatea şi a îmbunătăţit abilităţile de socializare ale animalelor (Wang J, Flaisher-Grinberg S, Li S et al. Antidepressant-like effects of the active acidic polysaccharide portion of ginseng in mice. *J Ethnopharmacol* 2010 ; 132 : 65-69).

CONTRIBUTION TO BIOELETRICAL PROPERTIES RESEARCH OF AREAS WITH ACUPUNCTURE (Abstract) : The research has as a goal the investigation of the bioelectrical behaviour of the acupunctural areas in order to obtain a scientific substantiation of the correspondence between the extreme – eastern medical tradition and the academical medicine. It is obvious that the Chinese traditional medicine knows a certain mechanism of ensurance of homeostasis of the organisms, a mechanism represented, according to the Chinese medical tradition, by the net of acupuncture points and meridians. The experimental data presented in this paper lead to the discovery of the fact that this net works as the fourth system of integration, the electrical – regulator one. The maintenance of the internal homeostasis of the superior organisms and their adaptation to the environment is ensured by the neuro – endocrine and circulatory systems through a mechanism described by Selye under the name of the Uncertain General Syndrome of Adaptation represented by the hypothalamo – hypophyso – corticoadrenal axis. The evolution of these systems and of their mechanisms can be supervised on the basis of the cortisole concentration. The research emphasized the direct proportionality between the cortisone levels and the variation of the electrical values of the acupuncture points, a fact that demonstrates the involvement of the net of acupuncture points and meridians in the maintenance processes of the homeostasis, control, adjustment and adaptation of the living organisms. Additionally, the analysis of the bioelectrical behavior of the acupuncture areas led to the conclusion that the morpho – functional substrate of this net is the conjunctive tissue. The physical – chemical properties of the interstitial connective tissue assures its working as an electro – regulator system on one side and as a harmonization agent of the neuro – endocrine and circulatory systems on the other side, this aspect being to be developed in a future paper.
Key words: POINTS AND MERIDIANS OF ACUPUNCTURE, ELECTRICAL CONDUCTIBILITY, QI ENERGY, ENERGY EXCESS OR DEFICIT, ELECTRICAL – REGULATOR SYSTEM

Identificarea unei structuri anatomice a punctelor şi meridianelor de acupunctură a eşuat în timp, câştigând în schimb tot mai mult teren teoria substratului bioelectric, teorie care are la bază ideea unei rezistenţe bioelectrice mai mică în punctele de acupunctură decât în zonele tegumentare înconjurătoare (1). Experimentele ulterioare au confirmat existenţa acestor gradiente de rezistenţă electrică şi pentru meridiane (2,3).

Astfel, s-au descoperit modificări ale configuraţiei bioelectrice a punctului, precum şi variaţii ale rezistenţei sale în caz de boală, s-a putut urmări o evoluţie ritmică a comportamentului conductibilităţii electrice cutanate şi dependenţa sa de factori ciclici exteriori (4,5). Mulţi cercetători au văzut în aceste manifestări electrice soluţia problemei determinării suportului ştiinţific al acupuncturii şi s-au imaginat corespondenţe între teoria tradiţională şi medicina modernă, făcându-se echivalenţa între "energia Qi" şi sarcina electrică, iar "deficitul sau excesul energetic" este interpretat ca rezistenţă electrică mai mare sau mai mică (6). Cercetarea noastră îşi propune ca scop investigarea experimentală a comportamentului bioelectric al zonelor acupunctice, recoltând o cantitate semnificativă de date necesare formulării unor concluzii statistice, necesare unei fundamentări ştiinţifice a corespondenţei dintre tradiţia medicală extrem-orientală şi medicina academică.

Urmare a prelucrării datelor bioelectrice recoltate s-a putut constata şi faptul că modelul de biosistem al MTC este unul realist, verificabil şi obiectivabil cu ajutorul metodelor moderne.

Este evident că medicina tradiţională chineză se bazează pe stăpânirea unui mecanism de reglare ce pare încă necunoscut medicinii moderne. Şcoala românească de acupunctură are meritul de a se situa printre pionierii acestei direcţii de cercetare şi astfel, Constantin D. (1977) explică efectele acupuncturii ca pe o acţiune de electro-reglare, de restabilire a echilibrului fiziologic şi refacere a homeostaziei electrice şi biochimice a organismului (7,8).

Urmând ideea prof. D. Constantin privitoare la acţiunea de electro-reglare a acupuncturii colectivul nostru şi-a propus să dezvolte cercetările în două direcţii principale :

- studiul teoretic şi experimental asupra mecanismului de electro-reglare a organismului uman ;
- evidenţierea parametrilor măsurabili cu valenţe diagnostice şi terapeutice specifici modelului fizic propus.

Prigogine (9. arată că pentru orice sistem termodinamic deschis (aşa cum este şi organismul viu) starea momentană de echilibru se caracterizează printr-un set de mărimi fizice măsurabile numit parametri de stare. Starea momentană de sănătate sau boală poate fi exprimată printr-o submulţime a mulţimii parametrilor de stare. Parametrii de stare ai acestei submulţimi se împart în mai multe categorii :

a. parametrii standardizaţi, recunoscuţi oficial, care dau informaţii asupra stării de sănătate şi sunt utilizaţi în practica curentă medicală pentru stabilirea diagnosticului ;
b. parametrii nestandardizaţi a căror valoare diagnostică nu este utilizată sau cunoscută ;
c. parametri necunoscuţi încă.

Există o teoremă în termodinamică care spune că alegerea sistemului complet de parametri de stare (un număr de parametri care caracterizează fără echivoc starea momentană a sistemului termodinamic) nu este unică. Cu alte cuvinte se poate găsi oricând un alt sistem de parametri de stare, format din alţi parametri şi care să caracterizeze» la fel de bine» starea momentană a sistemului termodinamic ca şi sistemul anterior de parametri.

Aceste consideraţii fizice ne permit să afirmăm că în cazul organismelor vii se poate găsi o altă serie de investigaţii paraclinice, care să ofere rezultate echivalente seriei oficiale de determinări.

Pentru a putea alege şi măsura parametrii semnificativi nestandardizaţi sau necunoscuţi este necesară alcătuirea unui mecanism de reglare specific acţiunii acupuncturii, respectiv a măsurării valorilor de conductibilitate electrică.

Existenţa acestui sistem reglator cu acţiune interferată cu cea a sistemelor nervos, endocrin şi circulator prin intermediul reţelei

de zone acupunctice este postulată de şcoala românească de acupunctură astfel : «având o rezistenţă electrică mică şi deci o conductibilitate electrică mare, aceste puncte pot fi considerate ca zone de conducţie care asigură stabilitatea structurii electrice a organismului. Sub raport electric, boala înseamnă o scădere a rezistenţei electrice şi o creştere a potenţialului electric în punctele cutanate corespunzătoare organului aflat în suferinţă. Acţiunea asupra lor are ca rezultat refacerea acestor parametri la valorile corespunzătoare stării de sănătate.» (10).

Aceste consideraţii fizice ne permit să afirmăm că în cazul organismelor vii se poate găsi o altă serie de investigaţii paraclinice, care să ofere rezultate echivalente seriei actuale de determinări.

Pornind de la acest adevăr am investigat experimental parametri electrici care pot fi puşi în directă legătură cu diagnosticul energetic din cadrul MTC. Am optat pentru măsurarea conductibilităţii meridianelor de acupunctură utilizând o tehnică derivată din tehnica de măsurare Ryodoraku.

Pornind de la testarea electropermeabilităţii pielii la un pacient cu edeme puternice datorate nefrozei cronice, Nakatani (11) descoperă pe toracele acestuia puncte cu o permeabilitate electrică mai mare (Ryodoten) decât cea medie, punctele fiind dispuse după meridianul rinichiului. Prin unirea acestor puncte cu o mai bună electropermeabilitate s-a obţinut o serie de curbe, numite Ryodoraku, identice cu tradiţionalele meridiane de acupunctură. Prin măsurarea electropermeabilităţii anumitor puncte de la încheietura mâinilor şi picioarelor pacientului, cercetătorul a constatat că se pot determina stările de excitaţie sau inhibiţie energetică a tuturor celor 12 meridiane.

Aceste puncte reactive electropermeabile se suprapun cu o bună aproximaţie punctelor P9, VS 7, C7, IS5, TF 4, IG 5, SP 3, F 4, R 4, VU 65, VB 40, şi S 42 bilateral.

Testarea se face cu o sursă de curent continuu de 12V şi 200 μA. Interpretarea datelor de măsură se face potrivit metodei Ryodoraku (12) prin dispunerea valorilor obţinute pe o diagramă numită *neurogramă*. În urma medierii valorilor se obţin trei regiuni : regiunea normală, regiunea meridianelor aflate în exces energetic şi regiunea meridianelor aflate în deficit energetic.

MATERIAL ŞI METODĂ

În cazul cercetării de faţă s-a preferat determinarea rezistenţei electrice şi nu a diferenţelor de potenţial datorită faptului că ţesuturile prezintă calitatea de *volum-conductor* (mediu bun conducător de electricitate). În consecinţă, activitatea unui organ intern, cum ar fi inima, creierul etc., are efectul unui dipol generat într-un ţesut situat în profunzimea organismului şi care influenţează întreg mediul bun conducător dimprejur, având răsunet până la piele (13).

Pentru realizarea măsurătorilor bioelectrice, respectiv a rezistenţei electrice cutanate atât în punctele de acupunctură cât şi la nivelul non-punctelor, s-a folosit un aparat de măsură a rezistenţei opusă de piele la trecerea unui curent electric test, de concepţie proprie, alcătuit după standardele tehnice specifice acestei destinaţii şi conform normelor de protecţie a subiectului investigat (fig. 1).

Toate tipurile de dispozitive pentru determinarea rezistenţei cutanate se bazează pe acelaşi mod de funcţionare, piesa principală fiind constituită dintr-un ohmmetru care produce un curent de 200 μA curent continuu, la 12 volţi.

P1 – potenţiometru carbon, se etalonează instrumentul de măsură prin scurtcircuitarea S1 cu S2. (se obţine indicaţia maximă pe scală – are acces permanent la panou).

P2 – potenţiometru semireglabil pentru reglarea sensibilitaţii microampermetrului. (se reglează de către constructor).

Ic1 – circuit integrat stabilizator de tensiune ce asigură o tensiune stabilizată de

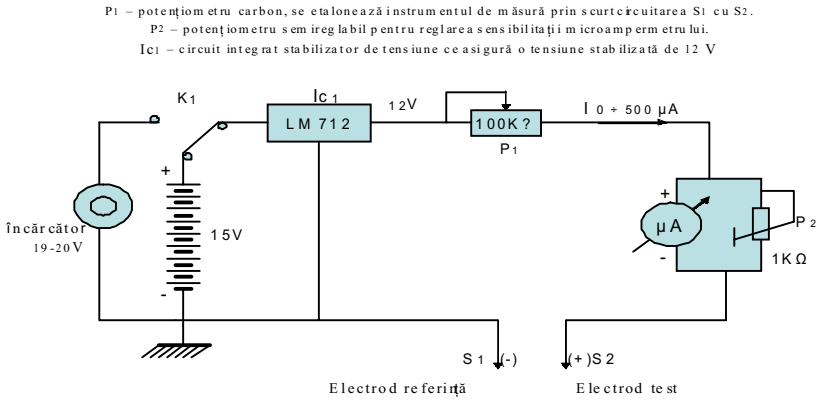

Fig. 1. Schema aparatului de măsură a rezistenţei electrice pe punctele de acupunctură

12 V, LM 712.

În cursul procesului de măsurare a rezistenţei punctelor de acupunctură se respectă legea lui Ohm :

$I = U/R$, în care $R = Rp1 + RA$

De unde :

$I = U/RP1 + RA$

Rezultă că :

$RA = R\,\mu\,A \,.\, RP2/P\mu A + RP2$

Calculul rezistenţei măsurate la electrozii aparatului de măsură (fig. 2).

R p – rezistenţa electrică a pielii,

Rint – rezistenţa electrică a circuitului în interiorul organismului explorat,

RX – rezistenţa electrică măsurată,

S1, S2 – electrozii de măsură,

Aparatul de măsură determină valoarea **Rx**, care, la rândul ei este formată din rezistenţa electrică a pielii (**Rp**) împreună cu rezistenţa ţesuturilor din interiorul organismului (**R int**).

Curentul explorator care pătrunde în ţesuturile subcutanate va alege traseul cu rezistenţa electrică cea mai mică. Acest traseu, conform cercetărilor, este reprezentat de ţesuturile ce constituie substratul meridianului de acupunctură.

Dacă rezistenţa electrică medie a pielii **Rp** este considerată constantă :

Rp ~ Constant,

Atunci, calculul lui **RX** rezultă din relaţiile :

1/RX = 1/Rp + 1/Rint,

de unde :

Rx = Rp . Rint/Rp + R int

Deoarece rezistenţa electrică a pielii este considerată constantă, rezultă că mărimea varibilă este rezistenţa **R int**, care este dată de circuitul din interiorul organismului.

Această mărime variază la nivelul punctului de acupunctură în funcţie de meridianul căruia îi este alocat punctul. De exemplu, electrodul de referinţă este plasat în mâna stângă, electrodul explorator măsoară rezistenţa electrică la un punct de pe încheietura mâinii dreapte, caz în care circuitul electric măsurat trece prin cele două membre superioare dar şi prin interiorul toraco-abdomenului şi invers.

Luând **Rp** constantă, rezultă că singura rezistenţă care variază este dată de cea a meridianelor parcurse de curentul explorator **R int**.

În consecinţă, măsurătoarea nu determină rezistenţa cutanată pe punctele de acupunctură, ci pe aceea reprezentată de traseul intern parcurs de curent de la un electrod la celălalt.

S-a verificat acest aspect şi de către noi, constatându-se că acest lucru este în general corect, dar valorile astfel obţinute sunt semnificative în cazul măsurării impedanţei, care implică şi procesele capacitive ale ţesuturilor, şi mai puţin semnificative în măsurătorile

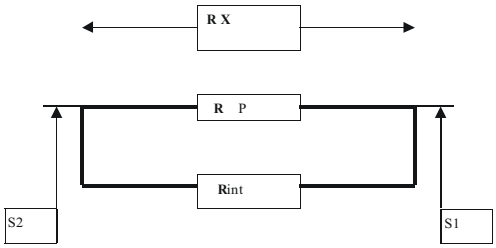

Fig. 2. Calculul rezistenţei măsurate la electrozii aparatului de măsură

de rezistenţă.

Ceea ce trebuie reţinut în acest context al procesului de măsurare este şi faptul că indicaţia la panoul aparatului este dată în valori de curent. În speţă, se măsoară valoarea de curent care reuşeşte să treacă prin circuitul explorat. În acest sens, ţesutul parcurs opune o anumită rezistenţă la trecerea curentului electric test, acest curent ce trece de opoziţia reprezentată de rezistenţă este măsurat în realitate, rezistenţa ţesutului fiind dedusă din relaţia care descrie legea lui Ohm : $R = U/I$.

Un alt aspect care rezultă din procesul de măsurare este legat tocmai de faptul că măsurătoarea nu se reduce la determinarea unei mărimi într-un punct, ci de-a lungul unui conductor. Acest tip de conductor nu este unul omogen, ci unul de tip anizotrop, format dintr-un hidroelectrolit specific ţesuturilor conjunctive ale organismelor vii.

Măsurătorile realizate pe conductori electrici clasici, metalici, oferă valori ale căror variaţii sunt liniare.

În cazul măsurătorilor pe structuri de tip hidroelectrolitic, aceste valori nu manifestă un comportament liniar.

În aceste cazuri se măsoară o rezistenţă compusă din mai multe variabile : lungimea traseului (l), secţiunea acestuia (s) şi rezistivitatea (ρ) acestuia.

$R = \rho \times l/s$

Deoarece secţiunea **s** este reprezentată de masa ţesutului cu cea mai mică rezistenţă, iar lungimea este constantă, rezultă că singura variabilă, cu cea mai reprezentativă semnificaţie, este dată de valoarea ρ a rezistivităţii electrice a ţesuturilor.

Alegerea tensiunii de 12 V şi a intensităţii de 200 μA decurge din faptul că aceste valori nu antrenează manifestări supărătoare (senzaţie de electrocutare, contracţii musculare), sau dăunătoare (arsuri, ca urmare a încălzirii locale a ţesuturilor, aşa numitele puncte fierbinţi).

Punctele de acupunctură prezintă caracteristici electrice particulare, care au fost studiate amănunţit în ultimii 50 de ani. Opinia generală, bazată pe rezultate experimentale, relevă că la nivelul acupunctelor se constată o scădere foarte importantă a rezistenţei sau a impedanţei electrice cutanate, până la 10 : 1, această caracteristică a permis construirea a numeroase detectoare de puncte, al căror principiu de bază rămâne măsurarea unei diferenţe de rezistenţă electrică faţă de rezistenţa medie a tegumentului (14,15,16,17). Întrucât măsurarea se face în curent continuu, noţiunea de impedanţă electrică se reduce la cea de rezistenţă, dispărând factorii dinamici de reactanţă (componenta capacitivă), deoarece curentul continuu este invariabil ca mărime şi sens (este staţionar) (18).

Cercetarea s-a efectuat pe trei loturi de subiecţi.

Primul lot, format din 486 persoane, 412 bărbaţi şi 74 femei, cu vârstele cuprinse între 18 şi 55 ani, a fost constituit din angajaţii de la CFS Săvineşti, Secţia Lactama 3, în cadrul controlului medical periodic preventiv, la care s-au prelevat în paralel parametrii bioelectrici şi analizele standard de laborator pentru noxele specifice locului lor de muncă conform normelor în vigoare. Cercetarea s-a derulat între iunie 1987- decembrie 1989.

Al doilea lot a fost constituit din 520 de voluntari, în cadrul Staţiunii Bălţăteşti, 210 bărbaţi şi 310 femei, cu vârstele între 16 şi 82 ani, în perioada 1986-1992, persoane neexpuse noxelor industriale, lot cu ajuto-

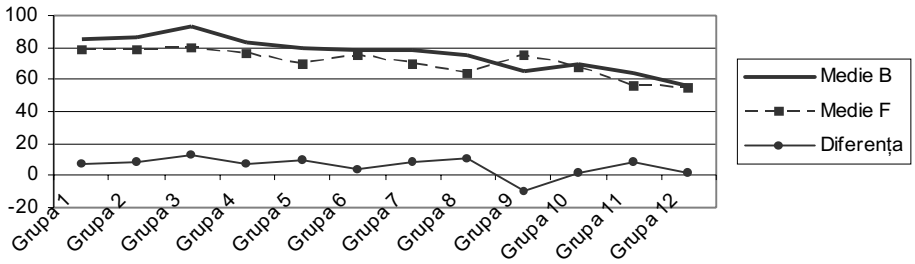

Fig. 3. Variaţia conductibilităţii cu vârsta şi sexul

rul căruia s-au verificat prin comparaţie variaţiile specifice unei activităţi desfăşurate în condiţii de viaţă modernă.

Al treilea lot a fost alcătuit din 106 angajaţi ai firmei Kober, Piatra Neamţ, dintre care 83 bărbaţi şi 23 femei, cu vârstele între 18 şi 55 ani, determinările fiind efectuate de-a lungul anului 1995, lunile ianuarie, martie, aprilie, iulie şi august.

REZULTATE

Evaluările datelor de conductibilitate electrică de la nivelul acupunctelor investigate conform metodei pe lotul de control format din muncitori agricoli neexpuşi noxelor industriale (lotul Bălţăteşti) au permis formularea următoarelor observaţii :

1. conductibilitatea electrică în acupuncte scade o dată cu creşterea vârstei subiecţilor (fig. 3).

2. la bărbaţi se constată o mai bună conductibilitate electrică decât la femei (fig. 3).

3. valorile culese în cursul primei părţi a zilei arată o conductibilitate electrică mai ridicată decât cele prelevate după amiaza (fig. 4).

Rezultate similare au fost obţinute şi de Dumitrescu (7) care a constat de asemenea că o creştere progresivă a potenţialelor electrice în punctele electrodermice situate pe craniu în primele ore ale dimineţii (8-11) şi o diminuare sau o reducere a lor spre orele de seara (19-22).

4. valorile electrice provenite de la determinările conform sezoanelor, se dispun de-a lungul unei curbe sinusoidale care indică creşterea conductibilităţii electrice începând cu luna februarie cu un maximum în luna mai, după care începe să scadă până ajunge la un minimum în luna decembrie (fig. 5).

5. comparând lotul de control cu loturile 1 Săvineşti şi 3 Kober, formate din lucrători în mediu cu noxe industriale chimice (benzen şi solvenţi organici şi lucrul în trei schimburi) s-a constat că aliura graficelor ce reprezintă derularea valorilor de conductibilitate nu respectă diagramele obţinute pe lotul de control.

Aceste constatări au atras atenţia asupra faptului că oscilaţia valorilor de impedanţă electrică din punctele de acupunctură ar putea indica de fapt probleme de adaptare a organismului la ritmul şi eforturile specifice mediului industrial.

Totodată a fost uşor de sesizat că există o relaţie directă între modul în care variază

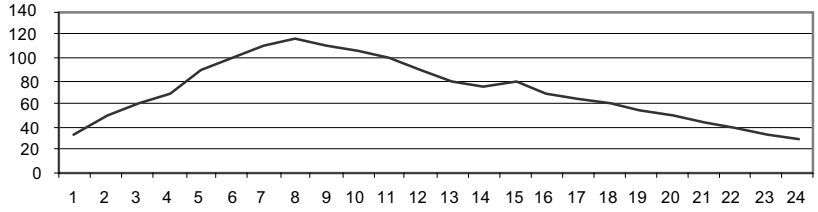

Fig. 4. Variaţia conductibilităţii de-a lungul zilei

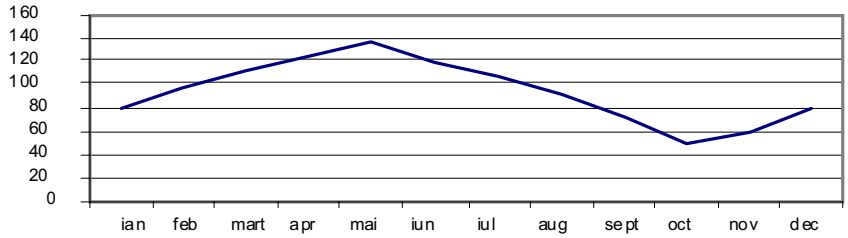

Fig. 5. Variaţia conductibilităţii dupa sezon

comportamentul electric în acupuncte şi curba nictemerală a cortizolului, hormon cu importanţă cardinală în acţiunile de adaptare.

S-a trecut la investigarea în paralel a valorilor cortizolului cu cea a valorilor bioelectrice constatându-se relaţia directă dintre cele două variabile.

Întrucât metoda de măsurare este o metodă invazivă, am constatat că testul de conductibilitate nu poate fi repetat cu rezultate mulţumitoare decât după circa 30-60 minute după prima testare. Aceasta dovedeşte că organismul sesizează curentul de test ca pe un factor perturbator extern şi ca atare, reacţionează prin modificarea parametrilor electrici ai însuşi sistemului de electroreglare testat.

Condiţiile stresante duc de asemenea la alterarea neurogramei ca urmare a aceluiaşi mecanism de reglare. Ingerarea alcoolului, a hranei sau a substanţelor medicamentoase duce la modificări notabile ale aliurii neurogramei cu alterări majore ale preciziei diagnosticului.

De aceea, este necesar ca prelevarea neurogramei să se realizeze în condiţii de repaus, pe nemâncate, în absenţa consumului de alcool, a stresului şi a tratamentului medicamentos.

Şi acest aspect demonstrează că oscilaţiile valorilor impedanţei electrice în zonele acupunctice sunt efectul perturbării induse de diferiţi agenţi stresori externi.

Important este că măsurătorile se referă la caracteristicile de profunzime ale ţesuturilor dependente de starea de sănătate a organismului şi nu la caracteristici de suprafaţă cum ar fi umiditatea tegumentului. Astfel, testând subiecţii imediat după baia salină, administrată ca tratament balnear la Băltăţeşti şi repetând testul după circa o oră, adică după uscarea tegumentelor şi reechilibrarea electrică, s-a constatat o aliură a neurogramei aproape identică cu aceleaşi valenţe diagnostice.

Rezultatele experimentale obţinute de autori au permis formularea unui model biofizic numit în literatură sistem electro-regulator.

DISCUŢII

Măsurătorile electrice efectuate de autori au confirmat existenţa şi coincidenţa unor zone cutanate cu rezistenţă electrică redusă cu cea a punctelor descrise de tradiţia medicală chineză.

Prin aceasta se demonstrează că proprietăţile funcţionale ale pielii se modifică dependent de activitatea substructurilor, activităţile lor circumscriindu-se unor zone foarte mici ca dimensiune pe piele (1-4 mm^2).

Această realitate ne obligă să apreciem că în timp ce potenţialul de activitate electrică este distribuit pe toată suprafaţa corpului, punctul, activat prin variaţia impedanţei, este conectat cu însuşi organul intern.

Noi am avansat deja ipoteza că această legătură se realizează prin intermediul ţesutului conjunctiv, schimbările fiziopatologice producându-se prin intermediul lichidelor extra-vasculare, care prin intermediul traveelor conjunctive din hipoderm sunt legate

direct de conductibilitatea pielii.

Căile prin care circulă acest tip de lichide sunt cele formate din ţesut conjunctiv lax, teoretic fiind coincidente cu meridianele Ryodoraku şi, de asemenea, cu clasicele meridiane (16,19).

Determinările obţinute de cercetarea de faţă corespund într-un mod semnificativ cu cele găsite şi de alte colective de cercetare.

Cercetările lui Târgovişte (1972) (8) au găsit pentru punctul de acupunctură valori ale rezistenţelor de ordinul 914+/-299 Ω la o profunzime a acului de 0,5 cm, iar la 2 cm: 502+/-85 Ω. Între punctele IG4 - IG15 a obţinut 1375 +/-525 Ω, iar pentru IG10 - IG11 : 1016+/-317 Ω.

Menţinerea homeostaziei interne a organismelor superioare este asigurată de sistemele neuro-endocrin şi circulator. Mecanismul prin intermediul căruia acţionează cele două sisteme este descris de Selye (20) sub numele de Sindrom genertal nespecific de adaptare, identificat în axa hipotalamo-hipofizo-corticosuprarenală. Măsura activităţii acestui ax este cel mai bine urmărită pe baza concentraţiei cortizolului (dozabil şi în sânge şi urină).

Dependenţa direct proporţională a variaţiei valorilor rezistenţei electrice cutanate din acupuncte şi meridiane cu variaţia concentraţiei cortizolului în stări atât fiziologice cât şi de stres, ne permite să concluzionăm că pe lângă cele trei sisteme de integrare cunoscute mai există un al patrulea, numit sistem electro-reglator.

Modelul teoretic al sistemului electro-reglator (presupus şi de alţi autori) este confirmat experimental de rezultatele cercetării prezente.

În plus, modul în care este demonstrat şi înţeles comportamentul biolectric în zonele de acupunctură ne-a permis să identificăm substratul morfo-funcţional al acestor zone ca fiind ţesutul conjunctiv interstiţial, acest aspect urmând a fi dezvoltat într-o lucrare ulterioară.

CONCLUZII

1. Modelul de biosistem descris de MTC nu contrazice cu nimic ceea ce ştiinţa medicală modernă a statuat legat de comportamentul acestuia pe baza verificărilor şi a rezultatelor experimentale, doar că a folosit un limbaj specific culturii şi vremurilor când acest tip de medicină a apărut.
2. Faţă de modul de gândire occidental, cel extrem-oriental intuieşte şi descrie sistemele vii în dinamică, prezentând toate fluxurile care străbat un organism: fluxurile de sânge, limfă, aer şi chiar pe cele reprezentate de biocurenţii electrici şi de schimburile termice, schimburi ce asigură corelarea şi adaptarea permanentă la mediul extern, constituind prin aceasta primul model de medicină holistică.
3. Aceste constatări au atras atenţia asupra faptului că oscilaţia valorilor de impedanţă electrică din punctele de acupunctură ar putea indica, de fapt, problemele de adaptare a organismului la ritmurile mediului extern natural, pe de o parte, dar şi eforturile de adaptare la modul de viaţă specific lumii moderne şi mediului industrial.

   Acest lucru este dovedit de existenţa relaţiei directe dintre comportamentul electric în acupuncte şi curba nictemerală, sezonieră şi de stres a cortizolului, hormon a cărui importanţă în acţiunile de adaptare este bine cunoscută.
4. Dependenţa direct proporţională a variaţiei valorilor rezistenţei electrice cutanate din acupuncte şi meridiane cu variaţia concentraţiei cortizolului în stări atât fiziologice cât şi de stres, ne permite să concluzionăm că pe lângă cele trei sisteme de integrare cunoscute, sistemul circulator şi neuroendocrin, mai există un al patrulea, numit sistem electro-reglator.
5. Deşi teoretic acest model a fost intuit şi

de alţi cercetători, prima dovadă experimentală în acest sens este adusă de autorii prezentului material.

6. Modul în care este explicat comportamentul bioelectric din zonele de acupunctură a permis identificarea şi justificarea ştiinţifică a faptului că substratul morfo-funcţional al acestora este reprezentat de ţesutul conjunctiv interstiţial, ca spaţiul al doilea extracelular.

DIFFERENTIAL EQUATIONS WITH SMALL PARAMETER WITH APPLICATIONS IN RADIOIMMUNOTHERAPY (Abstract): The Akzo Nobel research laboratories formulated this problem in their study of the penetration of radio-labeled antibodies into a tissue that has been infected by a tumor. This study was carried out for diagnostic as well as therapeutic purposes. The treatment of malignant diseases, after its primary treatment by surgery, is either by external beam radiotherapy, which is effective but local, or by chemoteraphy, which is effective but not selective. The radiotherapy labelled antibody has to be able to penetrate the whole of the tumour, whereas for imaging only uptake on the surface of the tumour is needed. Factors such as dose, rate delivered, tumor size, and radiosensitivity play a major role in determining therapeutic response, while target-to-nontarget ratios and, particularly, circulating radioactivity to the bone marrow determine the major dose-limiting toxicities. In this article, we introduced a system of differential equations with small parameter with applications in radioimmunotherapy. The problem consists of two partial differential equations. Both the equation of this system includes small parameter ε. We introduce the mathematical technique known as boundary function method for singular perturbation system. In this system, the small parameter is an asymptotic variable, different from the independent variable. We write solution of this system in a small parameter, and investigation of asymptotic solution for system. Using the program Matlab and numerical method Runge-Kutta, I did various simulations for different values of biological parameters presented in the model studied. **Key words**: RADIATION THERAPY, ANTIBODY, MALIGNANT, CANCER

Radioimmunotherapy is a newly approved cancer treatment that combines two types of therapies radiation therapy and immune therapy using monoclonal antibodies. Radioimmunotherapy (RIT) is use of radio-labeled antibodies in the therapy of cancer. The concept of localizing the cytotoxic radionuclide to the cancer cell is an important supplement to conventional forms of radiotherapy. In theory the intimate contract between a radioactive antibody conjugate and a target cell enables the absorbed radiation dose to be concentrated at the site of abnormality with minimal injury to the normal surrounding cells and tissues (1). A variety of approaches and combinations of this strategy are now being pursued. (RIT) has been more successful in the radiosensitive hematologic malignancies, for example lymphomas and leukemias as compared with small solid tumors (2). Obstacles to successful (RIT) have been recognized and strategies to overcome these hurdles and to improve efficacy are continuously being developed resulting in encouraging outcome particularly with locoregional routes

of administration in solid tumors. The results in solid tumors are somewhat less favorable but new strategies for patients with minimal residual disease using adjuvant and locoregional treatment are evolving (3). When your body detects something that does not belong, such as bacteria (pathogen), one way it eliminates the threat is to produce antibodies that bind to the protein shapes that are specific to the pathogen. (RIT) agents are man-made antibodies with different radiation components attached and is considered a targeted therapy, because the antibodies that deliver the radiation are specific to one type of cell. The ability of the antibody to bind to a tumor-associated antigen (a molecule that can stimulate an immune response) ensures that the tumor gets a high dose of radiation, which can kill the targeted cancer cells and nearby cancer cells, while normal tissuee only a minimal dose. This minimizes toxicity to normal tissues. Radioimmunotherapy is being studied in several cancers, but has shown the most promise in the treatment of blood cancers, such as leukemia and lymphoma (4).

MATHERIALS AND METHODS

Let us consider an original reaction diffusion system in one spatial dimension:

$$(P_\varepsilon)\begin{cases}\varepsilon\dfrac{\partial u}{\partial t}=\varepsilon\dfrac{\partial^2 u}{\partial x^2}-uv\\ \varepsilon\dfrac{\partial v}{\partial t}=-uv\end{cases}$$

which originates from the chemical reaction: $U+V\xrightarrow{\frac{1}{\varepsilon}}W$. Here U, the radio-labeled antibody, reacts with substrate V, the tissue with the tumor, and $\frac{1}{\varepsilon}$ denotes the rate constant (5). The concentrations of U and V are denoted by υ and ν, respectively. In the derivation of the equations (P_ε) it was assumed that the reaction is governed by mass action kinetics and in addition that the chemical U is mobile while V is immobile.

To model this penetration, the equations (P_ε) are considered in the strip:

$A_{N,T}=\{(x,t):0<x<M,0<t<T\}$

for some constants M, T, along with the following initial and boundary conditions:

$$\begin{cases}u(x,0)=0\\ v(x,0)=v_0\end{cases},\ \text{for}\ x>0$$

where v_0 is a constant, and :

$$\begin{cases}u(0,t)=\theta(t),0<t<T\\ \dfrac{\partial u}{\partial x}(1,t)=0,0<t<T\end{cases}$$

Let us now give some formal explications: the terms containing small parameter $0<\varepsilon<1$ are called perturbations. The extended model (P_ε) is then called perturbed, and the simplified model is called unperturbed. In this article, the model is formulated in terms of differential equations with small parameter multiplying the highest derivates.The use of a small parameter here is simply for definiteness. For example, a problem depending on a large parameter φ ccan be rewritten as one depending on a small parameter: $\varepsilon=\frac{1}{\varphi}$. Equation (P_ε) corresponds to the extended model. Sometimes small but not small enought to be ignored,and sometimes small but in a non-uniform way such that they are important locally. We work on the assumption that the chemical reaction rate constant is very high.

RESULTS

As we see, both part of (P_ε) contains the small parameter multiplying the derivate. The choice of a small parameter is connected with the order of the solution and the asymptotic sequence which describes the behaviour of the solution as $\varepsilon\to 0$.

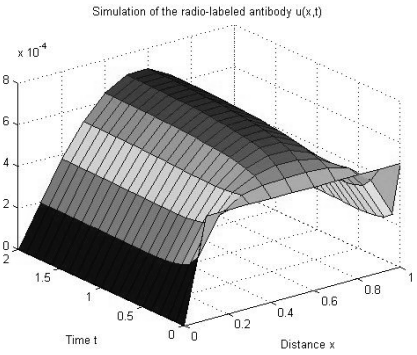

Fig. 1. Simulation of concentration radio-labelled antibody for parameter value $\varepsilon = 0.1$.

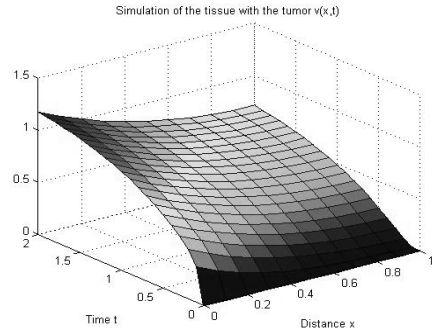

Fig. 2. Simulation of concentration the tissue with tumour for parameter value $\varepsilon = 0.1$.

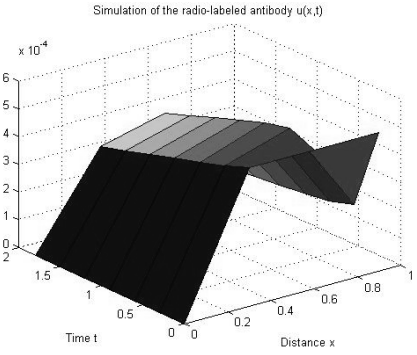

Fig. 3. Simulation of concentration radio-labelled antibody for for parameter value $\varepsilon = 0.1$. With increasing reaction rate by one tenth ,one can notice a more pronounced dynamic concentration radio-labelled antibody.

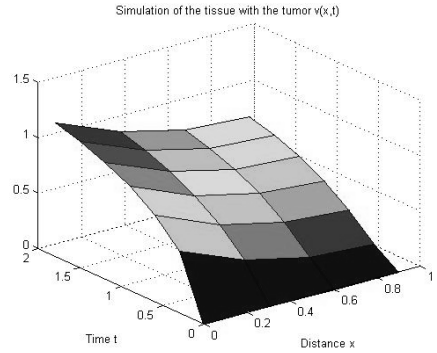

Fig. 4. Simulation of concentration the tissue with tumour for parameter value $\varepsilon = 0.01$

The fact that a small parameter ε multiplies a derivative in (P_ε) indicates that it is a singular perturbation problem.One class of such problems is immediately recognised if,on setting $\varepsilon = 0$, the order of the system of differential equations is reduced,such a reduced system cannot in general satisfy all the initial condition and boundary condition.Setting $\varepsilon = 0$ in (P_ε), we obtain :

$$(P_0)\begin{cases} \breve{u}(x,t) = 0 \\ \breve{v}(x,t) = F(x,t,\varepsilon) \end{cases} or \begin{cases} \breve{u}(x,t) = C(x,t,\varepsilon) \\ \breve{v}(x,t) - 0 \end{cases}$$

Equation (P_0) might be a simplified model of this process. We started out with two differential equations, and ended up saying that one of the differential equations degenerates to an algebraic equation. A system of two differential equations is quite different from a single differential equation with an algebraic constraint (6). The system (P_0) his is called the degenerate system. In the case when the boundary of the domain $A_{M,T}$ is no longer smooth, but contains corner points, the structure of the asymptotic solutions becomes more complicated in the vicinity of these points. We need to introduce a new type of boundary

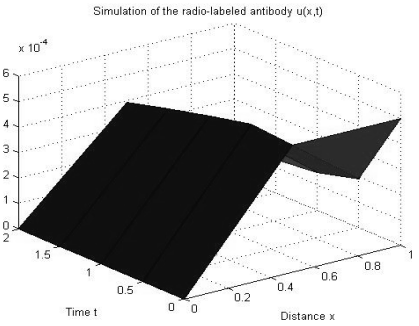

Fig. 5. Simulation of concentration radio-labelled antibody for parameter value $\varepsilon = 0.01$

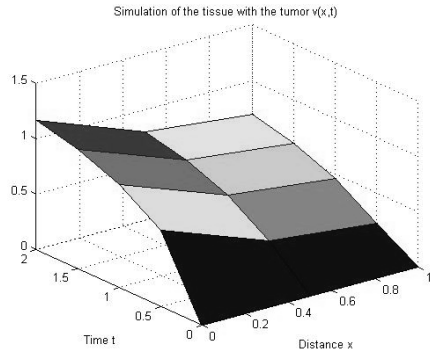

Fig. 6. Simulation of concentration the tissue with tumour for parameter value $\varepsilon = 0.01$

function, corner boundary functions, in the vicinity of the corner points. The corner points its :

$$O(0,0), A(M,0), B(M,T), C(0,T).$$

Usually the boundary functions are defined as solutions of partial differential equations, where the stretched distance along the normal to the boundary. We will seek the asymptotic expansions of the solutions of perturbed problem, initial and boundary conditions in the form :

$$\begin{cases} u = \bar{u} + \pi u + \omega u \\ v = \bar{v} + \pi v + \omega v \end{cases}$$

Here $\bar{u}, \bar{v}$ is the regular part of the asymptotic solution. The function $\pi u, \pi v$ is used for the boundary functions playing an important role near the sides of the rectangle, and the function $\omega u, \omega v$ is used for the corner boundary functions important in the vicinities of the vertices of the rectangle. Corresponding to the sides of the rectangle, π can be represented :

$$\begin{cases} \pi = \sum_{i=0}^{m} \varepsilon^i (\pi_i^{(1)}(x,\theta) + \pi_i^{(2)}(\mu,t) + \pi_i^{(3)}(x,\theta_1) + \pi_i^{(4)}(\mu_1,t) \\ \theta = \frac{t}{\varepsilon}, \theta_1 = \frac{T-t}{\varepsilon} \\ \mu = \frac{x}{\varepsilon}, \theta_2 = \frac{M-x}{\varepsilon} \end{cases}$$

The functions $\pi_i^{(1)}(x,\theta)$ representing the boundary layer near the side $t = 0$. The $\pi^{(1)}$ functions compensate for the discrepancy by the regular part of the asymptotic expansions to the boundary condition on the side $t = 0$. The boundary functions $\pi_i^{(1)}(x,\theta)$ compensating for the discrepancy in the boundary condition on the side $t = 0$, introduce additional discrepancies in the boundary conditions on the sides $x = 0$ and $= M$. These discrepancies are essential in the vicinities of the corner points $O(0,0)$ and $A(M,0)$, they decay exponentially as θ increases. Similar discrepancies are introduced by the functions $\pi_i^{(2)}(\mu,t)$ in the conditions on $t = 0$ and $t = T$, by the functions $\pi_i^{(3)}(x,\theta_1)$ in the conditions on $x = 0$ and $x = M$, and by functions $\pi_i^{(4)}(\mu_1,t)$ in the conditions on $t = 0$ and $t = T$. To compensate for these discrepancies we introduce corner boundary functions :

$$\omega = \sum_{i=0}^{m} \varepsilon^i (\omega_i^{(1)}(\mu,\theta) + \pi_i^{(2)}(\mu,\theta_1) + \pi_i^{(3)}(\mu_1,\theta_1) + \pi_i^{(4)}(\mu_1,\theta))$$

The functions $\omega_i^{(1)}$ are needed to compensate for the errors introduced by $\pi_i^{(1)}$ functions in the boundary condition along $x = 0$ and by $\pi_i^{(2)}$ functions in the boundary condition on $t = 0$. In initial-value approach of the perturbed ODE system (P_ε), initial guesses for equation's para-

meters are chosen and the dynamical equations are solved numerically. As a matter of fact, our concept of the perturbation search method was inspired by the prospect of basic perturbation theory.The principle of perturbation theory is to study dynamical systems that are small perturbation of integrable perturbed system . For this system,solutions can change on a time scale that is very short compared to the interval of integration, but the solution of interes changes on a much longer time scale (7).

DISCUSSION

The simulation of a single set of equation can be performed on a single workstation because the numerical integration of a system (P_ε) not very time consuming. The parameter values have highs impact on the accuracy of the model in representing real biological systems but these values are difficult to estimate experimentally (8) . The complexity of this biological process is revealed every time a mathematical simulation of the processes is carried out. The parameter ε estimation process usually implies time-consuming computations due to algorithms of linear regression and stochastic methods. Parameter estimation adjusts the model to reproduce the experimental results in the best possible way for a set of experimental data. When using an implicit Runge-Kutta method for solving a differential system, (P_ε) the order of the error can be reduced compared to what the classical theory predicts. Runge-Kutta methods have to advantage of being one-step methods, possibly having high order and good stability properties. The Runge-Kutta method for solving differential equations is fairly difficult to understand and rather involved algebraically to derive.

CONCLUSIONS

Radioimmunotherapy is usually delivered over a shorter period of time than chemotherapy. Although the length of treatment varies, most patients receive chemotherapy over the course of several months or occasionally longer. In contrast, radioimmunotherapy is usually delivered over a shorter period of treatment. Radioimmunotherapy is designed to target specific cancer cells. Chemotherapy, on the other hand, destroys any rapidly dividing cell, which often include non-cancer cells as well as cancer cells. Because the cells of the immune system, bone marrow, lining cells of the intestines, skin and hair follicles cells tend to be especially sensitive to the effects of chemotherapy, they are often damaged or destroyed along with the cancer cells. Regional administration of radio-labeled antibody can lead to inceased tumour binding if the antibody binds rapidly to the appropiate target antigen while still in the region compartment. System of differential equations studied in this article, contains small parameter ε Setting this parameter to zero $(\varepsilon = 0)$ leads to an- ofter easier- problem, the unperturbed or reduced problem.The solution of the unperturbed problem might be used as an approximation of the perturbed problem $(\varepsilon \neq 0)$. In this article suppose that we are interested in improving on this model by adding some previously ignored aspects or effects. So it seems that the relation between solution and model studied in this article is not continuous in the problem parameters ε. Whatever small ε we take, from a transparent and exact solution of the simple model at $\varepsilon = 0$,we abruptly face a far more complicated solution of a model that is just a little bit better. The approximation constructed in this article is almost always as asymptotic approximation, i.e. where the error reduces with the small parameter.

NOUTĂŢI

PARODONTITA MARGINALĂ CRONICĂ PROFUNDĂ – POSIBILĂ CAUZĂ DE ANEMIE SEVERĂ

Numeroase studii au demonstrat deja asocierea infecţiilor parodontale cu boli sistemice grave de tipul diabetului, bolilor cardio-vasculare, accidentului vascular, pneumoniei bacteriene şi cu naşterea prematură. Există însă foarte puţine cazuri raportate în literatura de specialitate care să demonstreze relaţia cauzală directă dintre parodontita marginală şi anemie deşi pacienţii cu inflamaţii parodontale prezintă concentraţii serice crescute ale markerilor inflamaţiei şi reacţii imune care pot supresa eritropoieza. Anemia asociată maladiilor cronice însoţeşte de obicei infecţiile cronice, bolile autoimune, cancerul şi bolile renale cronice dar şi parodontitele marginale severe pot constiui o cauză a acestei patologii. Pe de o parte, medicii dentişti au tendinţa să ignore semnele clinice şi paraclinice ale anemiei. Pe de altă parte, medicii de familie rareori corelează anemia cu leziunile parodontale grave şi în absenţa unei patologii sistemice grave, diagnostichează greşit afecţiunea ca fiind anemie feriprivă datorită nivelului scăzut de fier seric. Cazul prezentat subliniază şi demonstrează această relaţie cauzală. Pacienta, în vârstă de 50 ani, prezenta o anemie severă şi parodontită marginală complexă cu hiperplazie şi inflamaţie gingivală, pungi infraosoase active, mobilitate dentară şi depozite mari de tartru. Patologia orală împiedica o masticaţie adecvată şi implicit o alimentaţie echilibrată. Eliminarea celorlalte cauze posibile şi biopsia medulară care a arătat eritropoeză crescută ca răspuns la anemia severă, au condus în final la suspectarea parodontitei drept cauză posibilă a bolii. Tratamentul etiologic al parodontitei care a urmărit în primul rând controlul infecţiei şi reducerea inflamaţiei, urmat de extracţia dinţilor mobili şi protezare a determinat vindecarea completă a anemiei fără nici o altă medicaţie. În decurs de 4 luni, examenele hematologice au revenit la normal, simptomele clinice au dispărut şi pacienta a început să câştige în greutate (Lu S-Y, Eng H-L. Dramatic recovery from severe anemia by resolution of severe periodontitis. *J Dent Sci* 2010 ; 5 (1) : 41-46).

THE BODY AS SOURCE OF SIGNIFICANCE. INTERDISCIPLINARY PERSPETIVES (Abstract): This paper concerns a general theoretical aspect, followed by different examples which discuses the thesis in relation to major connected domains of research: psychology and philosophy. The thesis which we are arguing for is that the body represents a source of significance in the definitions of he self used as theoretical background in moral problems (philosophical aspect) and the explanations of the way the image of the self is consituted (psychological aspect). The philosophical "conclusion " is that the body, in its materiality, cannot be judged by the metaphysical dualism scheme, which assigns it a secondary role in the hierarchy of categories. From a psychological point of view, this paper tends to show that the body does not represent an accident of personality or a "prison of the soul" as Plato refers to it, but rather an element through which personality is built on and develops – and similarly, the mental and personality structures are those which allow the forming of corporeality and then the person's reference to it. **Key words**: BODY IMAGE, PERSONALITY DEVELOPMENT, MORALITY

G. Ryle numeşte dualismul cartezian „dogma of the ghost in the machine" şi îşi constituie demersul din The Concept of Mind ca o discuţie critică a acesteia. Doctrina dualismului se dovedeşte a fi un mit filosofic, organizat în jurul unei erori categoriale, prin care „the differences between the physical and the mental were represented as differences inside the common framework of the categories of thing, stuff, atribute, state, process (…). Minds are things, but different sort of things than bodies (…)" (1). Formularea dualismului, specifică filosofiei minţii, poate fi reţinută, deşi discuţia dualismului îşi găseşte aplicaţii diferite în psihologie, medicină sau chiar în discipline, speculative, ce pot fi trecute în contul, generos, al „filosofiei", precum antropologie sau, cum vom vedea, estetică. Una dintre condiţiile de posibilitate ale bioeticii stă, de asemenea, în precizarea statutului corporalităţii în raport cu persoana umană, în integralitatea ei. Altfel spus, în măsura în care corporalitatea poate pune o problemă etică, ea nu poate sta sub spectrul unui dualism ireductibil, care îi atribuie o cauzalitate strict mecanică. „Solidaritatea genetică", puternic documentată în cadrul discuţiilor contemporane, problemele legate de „dreptul de proprietate" asupra corpului propriu sau, mai evident, problema utilizării ADN-ului în scopuri medicale sau în scopul reproducerii presupun, în fundal, un răspuns la întrebarea Ce este corpul? şi care este relaţia sa cu celelalte instanţe ale subiectivităţii? În fond, problema dualismului se reiterează, cu o intenţie diferită faţă de contextul ei primar. Dualismul, înţeles în datele lui generale, presupune situarea responsabilităţii la nivelul unei instanţe care transcende corpul şi care este, în mod tradiţional, „adecvat" categoriilor morale: sufle-

tul. În măsura în care, însă, dualismul este pus sub semnul întrebării, corporalitatea poate şi ea să fie văzută, precum sufletul, ca sursă a imperativului etic. Definiţia agentului etic este, în mod esenţial, cea a unei instanţe „întrupate", iar nu a unui subiect „metafizic", lipsit de determinări mundane. Mai mult, încercări de a găsi eticii un fundament non-religios, non-metafizic şi totuşi universal în virtutea unor consideraţii istorico-antropologice vine în prelungirea aceleiaşi idei de a „integra" corporalitatea în constituţia subiectului moral. La fel, într-o problemă care trimite în mod strict la istoria filosofiei, încercarea lui J. Zammito de a citi sistemul critic kantian nu în sine, ci plecând de la cursurile sale, care l-au făcut celebru în epocă, de antropologie (2). Textul de faţă are ca intenţie asumarea aceleiaşi probleme a corporalităţii dintr-o perspectivă interdisciplinară. Pe de o parte, un demers care ţine de hermeneutica faptului cultural, pe de altă parte unul care ţine de sfera psihologiei vin să discute modalitatea în care corporalitatea capătă relevanţă din punct de vedere etic. Teza generală a textului ar putea fi aceea că atât determinări istorice ale codurilor etice, cât şi comportamente etice individuale depind de corporalitate, ca sursă de semnificaţie pentru ierarhiile de valori morale.

DE LA CORPUL ASCETIC LA CORPUL VIRTUAL

Un prim moment al discuţiei este reprezentat de monahismul egiptean al secolului IV. Unul dintre fenomenele paradoxale ale creştinismului, prin caracterul său paradigmatic dar, în acelaşi timp, inimitabil, monahismul pune în joc o anumită relaţie între corp şi suflet, care poate fi doar superficial înţeleasă ca negaţie a primului. Există, desigur, apoftegme ale Patericului care transmit amărăciunea nevoitorilor Pustiei la vederea celor trupeşti. Pe de altă parte, însă, modelul vieţii duhovniceşti a Părinţilor este chiar cel al lui Hristos Întrupat, iar dogma Sinodului ecumenic de la Niceea este apărată – şi transpusă în faptă şi viaţă - prin însăşi esenţa exerciţiului monahicesc. M. Henry, în Întrupare. O filosofie a trupului discută încă de la primele pagini despre teza originală a creştinismului, implicată în concepţia ioaneică a Logosului (3). Trupul capătă valoare în Creştinism tocmai datorită faptului că este, de fapt, receptacol al Oaspetelui de dincolo de vremi. Odată cu Întruparea nu doar Revelaţia îşi stabileşte modul său lumesc de a fi – anume, cel trupesc – ci, pe de altă parte, trupul însuşi îşi află originea cerească: „În lutul pământului nu există decât corpuri, şi nici un trup. Un lucru cum este un trup nu poate veni şi nu ne vine decât de la Cuvântul" (3). Una dintre distincţiile clasice care se ivesc cu acest prilej este cea dintre trup şi corp: primul, definit de fapt ca Viaţă, care simte fericirea şi suferinţa, care este indivizibil prin faptul că asumă şi pune la încercare un Sine; cel de-al doilea, divizibil, material, loc al senzaţiilor disparate şi al impersonalului biologic: „A fi viu înseamnă pentru cel viu puterea de a se încerca pe sine însuşi. Esenţa vieţii constă în purul fapt de a se încerca pe sine însăşi, de care e, din contră, lipsit tot ceea ce ţine de materie şi, în general, de lume" (3). Reabilitarea corporalităţii se face, pentru creştin, atâta vreme cât se poate concepe posibilitatea unui trup, al vieţii în concretul ei şi în unitatea desăvârşită pe care o presupune. Altfel spus, atâta vreme cât se poate vorbi despre transformarea corpului în trup, despre învierea acestuia sau, în continuarea consideraţiilor lui M. Henry, despre asumarea, la nivelul corpului, a unui Sine care se pune la încercare. Ascetismul vizează tocmai acest moment, al transformării corpului în trup. Avva Macarie Orăşeanul vorbeşte despre tensiunea „cărnii" – sarx – şi despre drumul care duce dincolo de ea. Chemat de fraţi să vină să mănânce, marele nevoitor le spune „Copii, voi trebuie să mâncaţi, pentru că încă sunteţi carne. Eu nu mai mănânc acum" (4). O complexă prezentare a fenomenului ascetic în formele sale multiple, nu neapărat creştine şi, mai ales, nu neapărat religioase poate fi întâlnită în lucrarea lui

G. Flood, The Ascetic Self. Subjectivity, Memory and Tradition (5). Două elemente pot fi schiţate, plecând de la această lucrare. Pe de o parte, modul în care ascetismul este o practică ce vizează, prin excelenţă, corpul. În al doilea rând, modul cum practica ascetică îşi înscrie semnele pe corpul pe care îl vizează. Corpul ascetic devine un corp „semnificativ", o sursă de semnificaţii tocmai datorită faptului că el se înscrie astfel într-o tradiţie, se dezindividualizează şi ajunge să poarte înscrise semnele transcendenţei. Ascetismul este cel care „dă Viaţă" corpului, îl transformă în trup şi astfel reduce diferenţa care, pentru grec, dar şi pentru modern, de pildă, îl separă de interioritate. La o primă vedere – fenomenologic vorbind, de la această primă vedere şi trebuie pornit – ascetismul este „the reversal of the flow of the body, which is also an attempt to revears the flow of time" (5). Ascetismul supune corpul unui referenţial format din mai mulţi termeni. Pe de o parte, este vorba de transcendenţă. Experienţa ascetică are la scop transformarea sinelui în sensul unei „donări" a acestuia către transcendenţă. Pe de altă parte, cosmosul, lumea, intervine prin aceea că ascetismul are ca efect dobândirea unei stări arhetipale a creaţiei, neatinsă de efectele corosive ale istoriei. În al treilea rând, tradiţia este cea care oferă ascetului un ritm şi o justificare printr-o naraţiune mai largă decât aceea a sinelui propriu. Astfel, ascetic este, într-un sens special, public : el trimite la o formă de intersubiectivitate ce are ca axa relaţia Avva-frate sau maestru-discipol. În acelaşi timp, un al treilea vine să fundamenteze şi să ofere un sens acestei relaţii : Divinul – oricare ar fi el –, cel către care sinele scetic se îndreaptă prin tehnici corporale. Ambiguitatea sinelui ascetic, cum numeşte G. Flood fenomenul, constă în următoarea situaţie : ascetul doreşte să îşi supună voinţa voinţei divine ; acest lucru se înfăptuieşte, paradoxal, prin asumarea unei intenţii ascetice, altfel spus prin supunerea voluntară a corpului unor tehnici impuse de tradiţie si prin care carnea (sarx) este în-viată şi donată sursei ultime a Vieţii. Evagrie sau Sf. Maxim Mărturisitorul descriu scenariul despre care vorbeam, acela în care soteriologia se deschide spre cosmologie. Corpul nu reprezintă, în acest joc, doar un efect secundar, nici doar un instrument. Trimiterea teologică, aceea că Hristos nu se întrupează într-un corp aparent, cum afirmau dochetiştii, ci real este valabilă şi în motivaţia ce stă în spatele asumării experienţei ascetice. Corpul este cel care, transfigurat prin tehnicile tradiţiei, conferă realitate unui Sine, unei interiorităţi care, în mod esenţial, este al întâlnirii cu celălalt : fie că este vorba de învăţător, a cărui taină o duce mai departe, fie că este vorba de cosmosul pe care îl limpezeşte, fie de Celălalt pe care îl lasă să vorbească prin propria voinţă. Corporalitatea capătă, pentru ascet, o realitate care este în acelaşi timp o miză. Subiectul ascetic este un subiect concret, istoric iar corpul îi constituie facticitatea din interiorul căreia experienţa monahală poate porni. În plus, corpul ascetului capătă, tocmai prin aceasta, o funcţie pedagogică importantă. Avva Arsenie capătă, în rugăciune, trup de foc ; avva Achilas îndepărtează cuvintele de la sine scuipându-le sub formă de sânge ; în cazul cel mai celebru, avvei Sisoe faţa i se luminează, devine ca soarele, apoi ca un fulger în clipa morţii ; avva Ioan cel Pitic, dar nu numai, se roagă să scape de patimi, iar apoi, mai fierbinte, sa le primească înapoi întrucât doar prin luptă sufletul se desăvârşeşte (4). Urmele trupului sunt astfel constitutive călugărului. Odată cu trupul, sufletul va învia, iar nevoirea pe pământ este una a unui suflet în trup, nu despărţit de acesta. Limitaţia pe care o poartă în sine carnea precum şi scopul ascezei, acela de a transforma corpul – plin de patimi –, în trup de foc fac din corpul ascetic o referinţă şi un pol de semnificaţie : condiţia trupească dă sens ascetismului, ea defineşte locul, contextul din care creştinul învaţă să vorbească despre sine şi despre Ceruri, ceea ce face ca monahismul să fie un continuu „urcuş duhovnicesc" iar nu un popas. O revalo-

rizare intensă a corpului intră, la sfârşitul modernităţii, în atenţia unor autori precum Foucault sau Deleuze. Pentru Foucault, „prin exerciţiile de abstinenţă şi de stăpânire de sine ce constituie necesara askesis, locul făcut cunoaşterii de sine devine mai important: obligaţia de a se pune la încercare, de a se examina, de a se controla printr-o serie de exerciţii bine stabilite, aşează problema adevărului – ce eşti, ce faci, ce eşti în stare să faci – în centrul constituirii subiectului moral"(6). Referindu-se cu precădere la spaţiul antic păgân, autorul francez subliniază legătura dintre asceză şi tehnicile corporale, cele legate de sexualitate şi problema adevărului. Corporalitatea intervine în mod esenţial în problema constituirii sinelui, întrucât existenţa raţională este de neconceput în absenţa unui set de reguli prin care cotidianul, mediul înconjurător sunt supuse unor tehnici „de optimizare" iar corpul devine parte a unei experienţe „unde raportarea la sine ia forma, nu numai a unei dominări, ci şi a unei desfătări lipsită de dorinţă şi frământare" (6). Nu este vorba de supunere la rigorile unei legi, nici de principii imuabile ale binelui şi răului. Mai degrabă, rigorile unei vieţi în acord cu sine şi în vederea unui sine îmbunătăţit sunt cele care determină scopul şi miza ascezei. Această situaţie se va schimba în modernitate. Prima secţiune din lucrarea închinată istoriei regimurilor de detenţie (7) poartă titlul Corpul condamnaţilor (Le corps des condamnes). Corpul devine important, arată Foucault, în măsura în care sistemele punitive sunt privite din perspectiva unor „tehnologii politice ale corpului" şi a unor metode de „subiectivizare" prin care ia naştere omul ca obiect – mai apoi, ca obiect de studiu ştiinţific. Ca şi în cazul spitalului modern, al secolului XVIII, regimul penitenciar modern conturează, prin tehnici ale controlului, ale organizării cotidiene, ale „reeducării" un joc de adevăr în care subiectul intră în calitate de obiect. Controlul, sistematizarea stau, în aceeaşi măsură, la originea exercitării puterii, a vindecării sau a discursului ştiinţific. Toate aceste zone ale modernităţii au ca origine legătura dintre adevăr şi putere: adevărul cu privire la subiect poate fi obţinut în măsura în care acesta se transformă de fapt in obiect experimentabil, catalogabil, inscriptibil în procedee metodice şi legităţi. Corpul joacă, în acest loc, un rol fundamental. În regimul penitenciar, ca şi în cel spitalicesc, puterea se exercită prin intermediul corpului. Bolnavul sau condamnatul nu mai reprezintă o prezenţă ambiguă, indefinită. Corpul este cel care îi transformă într-o prezenţă concretă, care se confruntă cu procedee uneori difuze, alteori instituţionale sau ideologice dar de fiecare dată materiale, tehnice (7). Modernitatea aduce aşadar corpul în prim-plan pe un traseu diferit faţă de cel discutat anterior în cazul monahismului, dar nu mai puţin relevant. El devine constitutiv subiectului, văzut acum ca miză a relaţiilor de forţe şi tocmai în acest mod capătă relevanţă. Putem vorbi, în înţeles modern, despre subiect deoarece corpul este cel care îl face vizibil din punctul de vedere al puterii, cea care ajunge vorbească despre adevăr. „Eliberarea corpului" ca fenomen al postmodernităţii nu face altceva decât să scoată corpul din aria de exercitare a puterii, condiţie specifică modernităţii. Estetizarea corpului, virtualizarea lui sunt fenomene care determină această nouă resemnificare. Din punct de vedere cultural, tatoo-art sau, mai larg, Body-art în ansamblul ei exploatează resursele semnificante ale corpului şi simbolistica pe care o poate sugera. Explorarea vizuală a corporalităţii în cinematografia contemporană în detrimentul unui joc de semnificaţii poate fi, de asemenea, amintită (8). Asumarea unor sincretisme orientale, de exemplu, ca alternativă la mentalul modern, european considerat unul al jocurilor de putere şi al dominaţiei violente oferă resurse pentru reevaluarea postmodernă a corpului, dintr-un punct de vedere al unei estetizări a acestuia, iar nu a unei „tehnologii politice". Mai mult decât enumerarea acestor fenomene, interesează rândurile de faţă răspunsul la întrebarea: cum

devine corpul în postmodernitate o sursă de semnificaţie? Ce stă la baza resemnificării sale postmoderne? Un răspuns poate fi sugerat plecând de la lucrările lui Mircea Eliade. Sacrul, arată savantul român, nu poate fi redus la dimensiunea sa istorică. El reprezintă de fapt un element constitutiv al conştiinţei umane ca atare, ţinând de nevoia esenţială a omului de a discerne între ceva semnificativ, adevărat, Real şi un alt domeniu care există în virtutea acestia, îi suportă determinările, întemeierea şi sancţiunile. De aici ideea supravieţuirii camuflate a miturilor în perioada contemporană, a mersului ireductibil şi coroziv al istoriei. Mitul supravieţuieşte, pentru că fără el, lumea devine de netrăit; şi, odată cu mitul, structurile sale de semnificaţie. În Sacrul şi profanul, Eliade discută despre semnificaţia cosmică a trupului: corpul reproduce, „la scară", cosmosul, în măsura în care coloana vertebrală devine asimilabilă Stâlpului cosmic, inima Centrului lumii sau respiraţia vântului (9). Cântarea cântărilor este, din acest punct de vedere şi dincolo de alegorismul ei, prototipul slăvirii corpului-cosmos şi înţelegerii nobleţii sale. Perioada contemporană, aşadar, recuperează aceste semnificaţii cosmice ale corpului, iar asimilarea postmodernă, deşi superficială, a textelor şi doctrinelor arhaice nu poate decât să înlesnească acest proces. Tatuajul, de pildă, îşi pierde funcţia originară, apotropaică; păstrează însă funcţia estetică şi devine semnificativ prin aceasta. În plus, „nudismul sau mişcările pentru libertatea sexuală absolută se bazează de pildă pe ideologii în care se pot desluşi urmele nostalgiei Paradisului, (…) când nu exista păcat şi nici ruptură între plăcerile cărnii şi conştiinţă" (9). O concluzie poate fi trasă privind această primă parte a studiului. Anume, este vorba de faptul că, din punct de vedere al rolului său cultural, corpul dispune de resurse majore de semnificaţie. Se poate gândi plecând de la corp, acesta nu este doar un efect, o iluzie sau o aparenţă. Corpul, în materialitatea sa, nu poate fi judecat după schema dualismului metafizic, care îi atribuie un rol subordonat în ierarhia categoriilor. Ascetismul, dominaţia tehnico-politică sau afirmarea identităţii postmoderne sunt gesturi pentru care corporalitatea conferă consistenţă gestului şi impune acestuia o anumită desfăşurare. Subminarea platonismului – sau, mai degrabă, a variantei sale vulgare – conduce la eliberarea reflecţiei despre exterioritate şi despre suprafaţă, despre efectele nebănuite ale corporalităţii. Foucault, comentându-l la un moment dat pe Deleuze, remarcă o posibilă ieşire din umbră, împotriva lui Platon, a epicureicilor, cei care ştiu să vorbească despre „emisii care vin din adâncul corpului şi care se înalţă asemeni unor dâre de ceaţă – fantome ale interiorului repede reabsorbite de miros, de gură, de poftă; pelicule absolut mărunte ce se desprind de pe suprafaţa obiectelor şi fixează în adâncul ochilor noştri culori şi profiluri (epiderme zburătoare, idoli ai privirii); fantasme ale spaimei şi dorinţei (zei de nori pe cer, frumos chip adorat, mizerabilă dorinţă dusă de vânt)"(10).

CORPUL ŞI CONCEPTUL DE SINE

Conştiinţa de sine se constituie firesc în devenirea umană având la bază corpul ca instanţă obiectivă stabilă pe de o parte şi reprezentările sale mentale, dinamice şi în continuă formare pe de altă parte. Interacţiunea suflet-corp, în felul în care ea intră în atenţia disciplinelor aflate în sfera psihologiei, face obiectul secţiunii de faţă. Corpul intervine astfel, voi încerca să arăt, în constituirea imaginii de sine şi, ulterior, în adoptarea unei atitudini morale şi în fundamentarea unor comportamente mentale dezvoltate, precum formularea unor opţiuni estetice. Invers, de asemenea, corporalitatea poate fi văzută nu ca un dat, ci ca o construcţie, aflată în schimbare şi care depinde de reprezentările sociale ale persoanei, de tipul de interacţiune avut cu cei din jur sau de tipul de personalitate. Această interacţine, în care ambii membri (corpul şi sufletul) joacă un rol la fel de important în definirea psihică a unei personae, va face obiectul precizărilor şi exemplificărilor ulte-

rioare. În perspectiva psihodinamică iniţiată de Freud « sinele corporal » se referă la experienţa subiectivă a senzaţiilor fizice, a funcţionării şi a imaginii corporale, aceasta din urmă devenind componenta activă a imaginii de sine (11). Corpul conţine şi exprimă trăirile afective individuale, fiind în acelaşi timp concept si fapt. Alfred Korzybski afirmă că „Harta nu este teritoriul" (12), ceea ce ilustrează oportun felul în care imaginea corporală şi imaginea de sine sunt doar reprezentări subiective având o înţelegere limitată a teritoriului. Corpul intermediază experienţa vieţii, o orientează şi o cenzurează, facilitând cunoaşterea lumii prin estomparea propriilor funcţii, transformate în reflexe. O reprezentare de sine incomplet construită sau greşit asumată, poate întârzia dezvoltarea afectivă iar individul va avea dificultăţi în a înţelege şi a integra propriile emoţii în diversitatea lor. În astfel de cazuri corpul devine din nou mijlocitor pentru exteriorizarea a ceea ce nu a fost înţeles şi nu poate fi exprimat prin cuvânt sau acceptat conştient. Corpul este purtător de simptome, martor indiscret al trecerii timpului şi al emoţiilor trăite de individ. Din punct de vedere biologic, dualismul corp – minte îşi pierde sensul. Corpul este generator al vieţii psihice şi al minţii prin sistemul nervos central. Neuroştiinţele au încă largi mistere de clarificat in ceea ce priveşte funcţionarea complexă a mecanismelor mentale, dar rezultatele actuale reuşesc să combată satisfăcător teza separaţiei categorice între minte si corp. La Peyronie (13), a fost printre primii care în Franţa secolului al 18-lea a presupus în urma cercetărilor sale, că mintea nu dispune de o distribuţie uniformă în creier. Secolele ce au urmat au înlesnit observaţiile neurologice prin apariţia tehnologiei de imagistică funcţională cerebrală cu ajutorul căreia relaţia dintre minte şi corp a putut fi analizată în condiţii neuropsihologice strict controlate. Brent A. Vogt şi Orrin Devinsky susţin (14) că mintea este adesea definită ca reprezentând „conştiinţa de sine", operaţionalizare pe care ei o demonstrează a fi reducţionistă. Copiii născuţi prematur şi izolaţi nu se dezvoltă normal din punct de vedere psiho-biologic iar experimentele de stabilizare senzorială realizate în încăperi special concepute provocau reducerea performanţei intelectuale, alterarea percepţiei, halucinaţii şi schimbări afective. Prin urmare teoria conform căreia sinele poate exista independent de evenimentele interne şi externe, este o concluzie extremă ce are la baza dualismul minte / corp ce nu poate fi integrat în discursul neuroştiinţelor. Pe de altă parte, nu toată activitatea senzorială şi motorie este activitate mentală, la fel cum mintea nu se identifică întregii activităţi cerebrale. Studiile arată că mamiferele nu sunt conştiente de evenimentele din cortexul vizual primar şi că interpretarea explicită a scenelor vizuale se realizează în alte arii cerebrale (15). În acelaşi sens, pacienţii orbi având leziuni corticale vizuale primare au acces la informaţia vizuală dar nu sunt conştienţi de ceea ce văd (16). Conceptul de sine în formare este ilustrat iniţial la individ prin experienţa şi conştientizarea propriului corp. Mai târziu pe parcursul dezvoltării personale, apare capacitatea de reprezentare si autoreflexie. În ultima etapă intervine intelectualizarea eului când sinele îşi dobândeşte natura abstractă eliberându-se de corp. Tot ceea ce va intra in atenţia individului mai apoi va trece prin filtrul subiectiv al sinelui susţinut de corpul de care s-a eliberat. Kinsbourne (17) cercetează dacă imaginea corporală este înnăscuta sau se construieşte prin experienţă şi învăţare. Există cazuri rare de copii ce se nasc fără unul sau mai multe membre (aplazia membrelor). 15% dintre aceşti copii raportează fantome ale membrelor pe care nu le-au avut niciodată. Prin urmare senzaţiile corporale sunt prezente în creier cu mult înainte ca experienţa să le justifice prezenţa. Faptul că majoritatea copiilor născuţi cu aplazie nu raportează membre fantomă, ilustrează importanţa mediului in menţinerea sistemelor neuronale preprogramate precum şi natura flexibilă a structurilor cerebrale (18). Conştientizarea propriului corp devine ast-

fel un proces dinamic ce nu presupune doar extragerea de informaţii preexistente dintr-o anumita arie cerebrală, ci descoperire şi învăţare graduală. Senzaţiile somatice par a fi cele care guvernează descoperirea propriei corporalităţi în detrimentul senzaţiilor vizuale care ocupă un rol secundar. Copilul se va percepe pentru prima dată ca individ pe măsură ce îşi va folosi corpul provocând senzaţii diferenţiate şi în părţile corporale pe care nu le poate vedea. În acelaşi sens, copiii orbi îşi formează o imagine a propriului corp în ciuda deficitului lor iar în cazul membrelor fantomă, pacientul integrează membrul lipsă chiar dacă nu îl poate vedea. Perceperea propriei corporalităţi stă la baza formării iniţiale a conceptului de sine şi continuă a marca semnificativ devenirea persoanei, a relaţiei ei cu lumea şi cu sine însăşi. Perspectiva cognitiv comportamentală propune un model coerent pentru a explica determinismul complex ce funcţionează în constituirea imaginii corporale, precum şi rolul acesteia în alegerea comportamentului individual. Interacţiunea mai multor factori ce acţionează asupra persoanei încă din copilărie, va duce în timp la construirea de convingeri şi credinţe specifice cu privire la parametrii de evaluare ai propriei imagini corporale, precum şi la importanţa acesteia în evaluarea personală globală. Cadrul cultural, experienţele interpersonale timpurii, însuşirile fizice, mediul familial si anturajul precum si trăsăturile de personalitate, fac parte dintre factorii ce vor contribui la conturarea schemelor şi atitudinilor cu privire la imaginea corporală si semnificaţia ei. În funcţie de contextul situaţional, aceste scheme se vor activa determinând gânduri automate ce vor condiţiona emoţii şi comportamente specifice. Dincolo de etichetele şi împărţirile teoretice funcţionarea interactivă a acestor factori se complică in realitatea psihologică intra si interindividuală. La fel cum unele situaţii pot determina activarea anumitor credinţe şi scheme, individul va fi predispus să se concentreze şi să selecteze situaţiile care vin în acord cu propriile credinţe. Noile experienţe trăite se vor adăuga la istoricul personal, întărind atitudinile deja existente sau modificând vag structura sudată de-a lungul mai multor ani. În acest sens Albert Bandura, teoreticianul învăţării sociale, vorbeşte despre „triada cauzală reciprocă" : factorii externi, de mediu, factorii interni personali si comportamentele individuale, funcţionează împreună, determinându-se reciproc (19). Aprofundând relaţiile ce leagă rolurile diferenţiate ale fiecăruia dintre factorii deja amintiţi, considerăm util a-i descrie mai amănunţit. Cadrul cultural impune standarde şi modele estetice, caracteristicile fizice valorizate şi cele dezaprobate, precum şi importanţa imaginii fizice, semnificaţia ei într-o anume societate. Ce este atractiv şi ce înseamnă a fi atractiv. Tot aici se decid caracteristicile de gen, atributele fizice care definesc si diferenţiază conceptele de feminitate şi masculinitate, se stabilesc idealuri plasate şi prezentate în contexte bine conturate (20). Astfel de exemplu, societatea occidentală propune ca ideal de feminitate un trup tânăr, înalt şi foarte slab asociat adesea cu ideea de succes, fericire si dezirabilitate. Femeile vor internaliza acest model investindu-l cu o importanţă semnificativă globală în cadrul evaluării personale, ceea ce le va afecta la nivel perceptual, afectiv, cognitiv si comportamental. Ca urmare a comparării sociale, la nivel perceptual femeile riscă a se considera supraponderale doar pentru că nu corespund standardelor. Distanţa de netrecut dintre imaginea ideală nerealistă şi imaginea percepută duce în plan afectiv la stări distimice, stimă de sine scăzută şi nemulţumire legată de imaginea corporală. Din punct de vedere cognitiv, transformarea aspectului fizic în criteriu central al evaluării globale, va duce la concentrarea excesivă asupra mesajelor legate de acest aspect şi selectarea lor preferenţială pentru construirea imaginii de sine. Comportamental, femeile se vor angaja in activităţi menite să le ajute sa îşi împlinească idealul estetic stabilit. Pentru un sistem complet, tot mediul cultural va stabili şi va crea mijloacele pen-

tru atingerea idealurilor fizice propuse: moda, dietele, operaţiile estetice. În funcţie de acest sistem individul îşi va forma propriile credinţe şi aşteptări cu privire la imaginea sa corporală, va stabili cum se plasează faţă de modelele impuse şi ce importanţă au acestea pentru el, ceea ce va influenţa felul particular de raportare la evenimentele trăite. Chiar dacă societatea stabileşte standarde şi criterii de evaluare ale imaginii corporale, experienţele interpersonale timpurii şi mediul familial au un rol esenţial în influenţarea felului în care individul se va situa în raport cu acestea. Opinii, aşteptări şi feedback verbal sau nonverbal sunt transmise mereu în interacţiunile cu prieteni, colegi, membri ai familiei sau chiar persoane străine. Imaginea corporală este în continuă formare de-a lungul vieţii şi devenirea ei va depinde în parte de compararea socială şi feedbackul primit de la persoanele semnificative din apropierea individului. În copilărie acestea vor fi părinţii, în adolescenţă o importanţă deosebită o vor avea colegii şi prietenii iar la vârsta adultă partenerul romantic va fi cel care va mijloci devenirea imaginii corporale. Cu toate acestea, experienţele timpurii au o importanţă capitală în formarea schemelor cognitive, a credinţelor şi atitudinilor şi prin urmare părinţii şi familia vor avea un rol esenţial. Fisher, Fisher & Stark arată că felul în care părinţii se vor raporta la propriul copil depinde în parte de discrepanţa dintre imaginea ideală, expectanţele lor despre copilul ce se va naşte şi felul în care acesta arată in realitate (21). Criteriile fizice dorite de părinţi pentru copiii lor par a fi asemănarea lor cu membrii familiei şi absenţa malformaţiilor fizice. La baza unei imagini corporale sănătoase şi stabile se află un mediu familial afectuos, tolerant şi atent la nevoile copilului. Fraţii şi surorile au de asemeni un rol important în a stabili importanţa aparentei fizice în evaluarea personală (22). Atât experienţele interpersonale cât şi informaţiile primite din mediul cultural vor fi filtrate şi asumate de indivizi într-o varietate de forme în funcţie de trăsăturile lor de personalitate. O variabilă importantă în acest sens este stima de sine care va influenţa semnificativ evaluarea propriei imagini corporale. Astfel, satisfacţia cu privire la propria aparenţă fizică va corela cu o stimă de sine ridicată şi este un bun predictor pentru stabilitatea acestui raport în faţa diferitelor evenimente exterioare ce pot interveni, în timp ce o stima de sine scăzută predispune persoana la o evaluare preponderent negativă, mai dependentă de factorii externi. Trebuie însa menţionat că şi de această dată interacţiunea este reciprocă. În perioada timpurie, când personalitatea este in formare criticile sistematice cu privire la aspectul fizic pot determina o evoluţie problematică în mai multe planuri ale personalităţii, marcată de neîncredere în sine. Aceasta va deschide cercul vicios permiţând persoanei a se concentra preferenţial asupra mesajelor şi evenimentelor ce vin a confirma ideile sale despre o imagine corporală deficitară, ceea ce îi va întări credinţele şi va perpetua eventual o stimă de sine globală scăzută. Un alt factor de personalitate ce ar putea influenţa formarea imaginii corporale, este conştiinciozitatea. O persoană perfecţionistă îşi va stabili standarde înalte pe care le va urmări cu stricteţe. Aceste criterii se pot referi şi la aspectul fizic. Pentru că adesea aparenţa fizică nu stă doar în puterea individului, eforturile de voinţă se pot dovedi puţin eficiente lăsând persoana frustrată. Dependenţa/independenţa de grup arată în ce măsura persoana îşi este suficientă sieşi, luând decizii şi formându-şi convingeri pe cont propriu. O persoană influenţabilă, dependentă de grup, va fi mai expusă evenimentelor şi părerilor externe astfel încât şi imaginea corporală poate avea o structură mai vulnerabilă (23). Factorii de personalitate nu acţionează izolat, mai importantă fiind interacţiunea dintre ei, precum şi felul în care vor plasa individul în mediul lui cultural, social şi familial. Nu în ultimul rând însuşirile fizice în forma lor absolută vor stabili unde se plasează individul la nivel obiectiv faţă de standardele culturale

estetice ale epocii, precum şi felul în care va fi perceput de ceilalţi. Persoanele cu deficienţe fizice de natură congenitală par a prezenta un risc crescut de a fi nemulţumiţi de propria imagine corporală, prezentând stima de sine scăzută şi întâmpinând dificultăţi interpersonale. Cu toate acestea, toţi ceilalţi factori ce conlucrează complex în formarea individului, fac evoluţia acestor persoane mult mai puţin previzibilă. În timp ce un număr semnificativ dintre ele vor fi afectate de situaţia lor, altele vor avea o evoluţie normală învăţând chiar să profite de pe urma a ceea ce le face diferite sau reducând diferenţa fizică la un rol minor în imaginea lor corporală (24). Obezitatea pare a fi stigmatul social cel mai dificil de suportat. Majoritatea oamenilor consideră că indivizii îşi pot controla corpul spre deosebire de rasă, naţionalitate sau sex, fac atribuiri interne, şi apare tendinţa de a învinui. Persoanele suferind de obezitate vor interioriza aceste opinii şi vor tinde a se culpabiliza şi a se simţi vinovate (25). Ca exemplu suplimentar, în societăţile occidentale în care tinereţea fizică este valorizată, angoasa îmbătrânirii este acutizată de focalizarea indusă asupra aparenţelor corporale (26). Corpul este supus schimbărilor sistematice iar imaginea corporală este un concept dinamic ce trebuie mereu ajustat şi adaptat în consecinţă. Din punct de vedere biologic şi psihologic mintea şi corpul sunt inseparabile. Chiar dacă neuroştiinţele nu au putut încă stabili cu exactitate unde anume în sistemul nervos central se găseşte localizat „spiritul" iar psihiatria şi psihologia încă încearcă a clarifica mecanismele prin care zbuciumul sufletesc determină tulburări somatice semnificative, este însă evident că încercarea de a separa trup şi spirit este una artificială. La fel, încercarea de a contura identitatea unei persoane făcând abstracţie de modul în care aceasta îşi asumă şi înţelege corpul. Persoana umană, ca actor moral, de pildă, se constituie în bună parte şi din felul în care aceasta se raportează la sine ca având un corp şi suportându-i, inevitabil, limitările. Corpul, din perspectivă psihologică, nu reprezintă un accident al personalităţii sau o „închisoare a sufletului" după cum o numeşte Platon, ci un element prin care aceasta se construieşte şi se dezvoltă, după cum, în mod reciproc, structurile mentale şi de personalitate sunt cele care permit constituirea şi apoi raportarea la propria corporalitate.

CONCLUZII

Textul de faţă poate fi citit ca o încercare de a argumenta şi preciza o afirmaţie a lui D. Le Breton din Antropologia corpului şi modernitatea: „Corpul funcţionează ca o frontieră ce delimitează în faţa celorlalţi prezenţa subiectului. El este factor de individuaţie" (27). Ascensiunea individualismului, arată Le Breton, este legată de conştientizarea corpului ca limită, ca barieră a persoanei. Odată cu aceasta, interesul pentru corp ca posesiune a individului, ceea ce trimite, automat, la una dintre sursele fundamentale ale dualismului de la care am pornit: odată cu individualismul, corpul uman nu mai reprezintă, ca în societăţile arhaice, o legătură cu cosmosul, mai bine zis o parte a acestuia. Prin corp, omul nu se mai integrează în cosmos, ci se delimitează de celălalt. Corpul desparte şi, odată cu această funcţie pe care o capătă, el însuşi devine doar un efect de suprafaţă al sufletului, adăugat acestuia, iar nu cosubstanţial cu el. Ceea ce am încercat să arătăm, în textul de mai sus, este că această funcţie nu este dusă până la capăt. Corpul nu doar este semnificat, ci şi semnifică la rândul lui. Este activ, ştie să vorbească, iar tăietura pe care o produce între un sine şi un celălalt ia, de fapt, forma corpului, îi suportă determinaţiile. Identitatea se constituie prin corp, iar interioritatea nu poate fi abstrasă tensiunii în care stă cu cel care o „delimitează", anume corpul. Cele două secţiuni largi ale textului de faţă descriu această tensiune în mod diferit, dar complementar, atât din punctul de vedere al problematicii, dar şi al metodei. Rezultatul este sublinierea relevanţei corpului din punct de vedere etic, dar şi din punct de vedere al constituirii

propriu-zise a imaginii despre sine, a interiorităţii. Asumarea unei probleme de bioetică sau a unei decizii cu privire la întrebările acesteia este susţinută, în fundal, de perspectiva unei persoane „întrupate", diferită de subiectul eticii clasice, aflate în umbra metafizicii. Nu este vorba, altfel spus, despre o subiectivitate autonomă, definită prin atribute „tari" atemporale, supramundane, precum autonomie, substanţialitate sau libertate, ci de un subiect finit, marcat de puterea temporalităţii, a fragilităţii şi a inevitabilelor eşecuri ale lumesculu.
